Priscilla F——, a widow aged thirty-eight, was admitted under Dr. Tilbury Fox on May 19th, 1876, when I was the assistant to the skin department, so that she has been under my observation the whole time. Her father died of pneumonia. Her mother accompanies her to-day, and is quite healthy. She has been married ten years, and has had six pregnancies, but each one aborted at about the sixth month; there is no other evidence of syphilis. The husband was a circus man, and she travelled with him, leading a very hard life, which broke down her health. Three years before admission she got wet, and sat in her wet clothes in the circus. The next morning she had pains all over her body, especially in the joints, which were swollen, the knuckles, wrists, and ankles being specially affected. The joints were so stiff that she could not bend them without difficulty. Soon she experienced a sense of tightness of skin across the chest, which extended to the collar-bones and up the neck to the mouth, and the skin "felt like a cord" from the chest to the chin. The fingers became drawn down into the hand, much more than they are now, and pressure, continued for some time, produced pitting of the hands. The feeling of tightness of the skin gradually spread up the arms and over the face, and wasting set in; the legs became affected also, but less than the arms, and there was a feeling of tightness at the knees when she stooped, but the legs have not wasted very much. Pains, generally of a gnawing character, and sometimes pricking, were experienced, and are still felt at times. For about a year previous to admission there has been no change in the condition of the skin; for the last two years she has been subject to fainting attacks occasionally, but lately they have been more frequent and severe. She is often giddy, and has had occasional attacks of numbness in the lips and left side of the face, and also in the right leg, but only of a few minutes' duration. Condition on admission: The face is much wasted, there are no wrinkles or folds, and the skin is tightly stretched over the bones; but on the forehead with great difficulty the skin can be slightly pinched up. The lips are shrunken and tightly stretched over the teeth, and the incisors are loose and appear to be falling out, but the gums are not very hard now. The venous radicles are dilated and mottle the otherwise extremely pale surface. There is general desquamation of the epidermis in fine scales, and scattered papules appear from time to time, which ultimately leave only a patch of scales in their place. On the chest the skin is tight and parchment-like as far as the third rib, and in a lesser degree down to the level of the ensiform cartilage; below this the skin is normal. At the back the disease extends over the scapula, but is less marked at the supra-spinous fossa, and ceases between the shoulders. The hardness is most marked in the arms, where the skin is much thickened, but the muscles and fat are extremely wasted. There is an increase of pigment in the axillæ and the upper third of the area on the inner side. The right arm is flexed to a right angle at the elbow; the bony prominences are very conspicuous through the stretched skin, and ulcerated in two places from being knocked. The right hand is extremely atrophied, the skin quite smooth and shiny, and the fingers semi-flexed in a claw-like manner, the little one being nearly flexed on to the palm, though there is slight power of movement in the metacarpo-phalangeal joint, but none in the other joints. The wrist is ankylosed, but she has slight power of rotation from the head of the radius being partially free; the distal phalanx of the thumb is drawn back by the contracted extensor, but the other is straight. The front of the thigh is in the same condition as the arms, though less developed. The urine was 1012, with no albumen or sugar. The heart had no thrill, but there was a systolic and a presystolic murmur at the apex, both conducted towards the axillæ, and reduplication of the second sound at the base. Such was her condition in 1876. She was treated with iron and other tonics and cod-liver oil, and diligent friction with simple ointments. Under this treatment gradual improvement took place, and she has now recovered as far as the severely damaged tissues would admit. Her face, as you see, is still thin and expressionless, for not only the fat but the muscular tissue was atrophied. The skin is now easily pinched up and freely movable, but it is still pale, except where mottled by telangiectic vessels, which are very abundant. The upper lip is shortened still, but all the front teeth have dropped out, so that the shortening is less noticeable than before. The arms are much wasted, but the stiffness and hardness of the skin have disappeared and the wrist has recovered its mobility. The hands, however, are hopelessly crippled, for though the skin is movable, and perhaps there is a little more movement at the metacarpo-phalangeal joint, it is not of any material use, as the rest of the finger-joint is as completely flexed as ever. If you compare her hands with the preceding case you will see how exactly one is the counterpart of the other, with the exception that the wasting and flexion are somewhat greater in this patient. This is the condition that Ball described as "sclerodactylie," though another name is scarcely needed for a single phase of this disease. Deep as is the abyss into which such patients as we see before us are plunged, there appears to be a lower depth still. After a time in these patients the disease comes to a standstill, and though they generally lose flesh, at least their life is not in danger, unless from an intercurrent malady which they are less able to resist than they were before. In the other cases to which I allude the disease is progressive, with long periods of rest, it is true, but steadily downwards. Such a course is fortunately very rare, and I will merely quote in abstract one of Sir Erasmus Wilson's cases to illustrate it. The patient, aged fifty-seven, was secretary to a society, when the disease began, in 1866, with repeated attacks of swelling of the hands. Some months later the hardness and contraction made themselves sensible, and he experienced pain in the joints and tightening of the skin; then the front of the chest and neck became affected, and a little later the shoulders and arms; there was also a slight impediment in swallowing. In 1869, when Wilson saw him first, his hands, face, breast, and right foot were affected with atrophic scleroderma, and he was very feeble; voice, back, and knees, weak. In 1873 the disease had progressed and he was rather worse in every way, and deglutition was more difficult. In 1876 the left foot was attacked, like the right. In 1875 he died; it is not stated in what way. The condition had thus lasted nine years, with gradual progression and undermining of the general health.

Let us now compare our last two cases with each other, and then with the first two. In both the disease began with articular pains, but in the last it is clear that there was acute rheumatism present. In this patient there is a definite history of exposure to wet and cold immediately preceding the scleroderma, but in Jane E——, though probable, it cannot be definitely established. This association of acute rheumatism and heart disease with scleroderma is not an infrequent occurrence, and you will remember that this was the case in the child whose history I briefly related; but, as is so common in children, the brunt of the disease fell on the heart, the articular manifestations being slight. What is, then, the relation of acute rheumatism to scleroderma?—is it etiological? I scarcely think so. While there are, on the one hand, only a moderate proportion of scleroderma patients in whom the two diseases are associated, there are many scleroderma cases in which there has been no antecedent or associated rheumatic fever, while scleroderma would not be so rare if so common a disease as rheumatic fever was of direct etiological importance. I regard them, and also ordinary articular rheumatism which frequently accompanies scleroderma, as being due to a common cause—viz., exposure to cold, which is one of the most frequent and important causes of scleroderma. No doubt persons who have suffered from rheumatism are abnormally sensitive to cold and wet, and the same is true of people liable to erysipelas, and in this way rheumatism and erysipelas may

predispose to scleroderma among other things. With regard to the frequent association of valvular cardiac disease with scleroderma, it is more reasonable to consider it the direct outcome of rheumatism than to assume that it is due to a sclerosis of the valves analogous to the affection of the skin, though the possibility of such an origin cannot be denied.

To return to our last two patients. Both of them show their disease in the atrophic form, contrasting thus with the first two patients, though, as I have said, they do not represent anatomically but clinically opposite conditions. In this contracted condition the disease attacks the surface of the skin, the papillary layer, and epidermis, as well as the deeper part of the corium, and the subcutaneous tissues, which are alone attacked in the other form. The result is that the disease is much more obvious to the eye. The ivory-white colour which characterises nearly the whole of the skin of the affected area of Jane E——, unlike the white patch in Jane R——'s thorax, marks no mere deficiency of the pigment, but indicates a profound alteration of an atrophic character in the elements of the skin, due to defective nutrition. Great as that change is it is not irretrievable, except where there is complete destruction of elements, as we may see in the case of Priscilla F——. We shall consider this condition of skin again when discussing the other forms of scleroderma, as in them it is more invariably present. Both these patients have the deformity of the hands and forearms the same in every particular except degree, and in Jane E—— you will remember the upper and lower extremities were affected in precisely corresponding areas. Owing to the alteration of colour we can determine more easily the line of demarcation in this form, which, as we have seen, is rarely possible in the other. The symmetry is as exact here as in the other cases, both as regards the parts affected and the parts exempt, as in the small free areas in the knee- and elbow-joints, which allowed free motion of those joints; but all patients are not so fortunate, frequently the tissue round the tendon of the biceps is infiltrated and forms a thick band of hard tissue traversing the front of the joints like a cord, and firmly fixing the joint in a more or less flexed position. In both these patients there was some increase of pigmentation in parts, but this was insignificant compared to what occurs in some cases, as, for instance, in Jane R——. Interesting in this relation is Dr. John Harley's case, in the Medical and Chirurgical Transactions, vol. xli., where there is a plate of the skin in the clavicular region, showing a network of dilated vessels like those of Priscilla F——, but more regularly retiform, and between the vessels streaks of light-brown pigment, though the most extreme instance of pigmentation in connexion with this disease is recorded by Mr. Gaskoin in the fiftieth volume of those Transactions. In many respects this is a most interesting case. At present I will only refer to the pigmentation. The patient, who was a brunette, "became very dark, especially below the waist, and in the extremities. In depth of colour the skin resembled that of a negress, or one of the darkest races, but the staining was otherwise than uniform. In the darkest parts there were yet darker portions interposed. Thus, in spite of glossiness of surface, the aspect was singularly disagreeable, and the well-washed integument was always spoken of by her as being dirty. The locality of the joints was clearly indicated by an increased depth of tint; the neighbourhood of the coxal articulation was shown externally by a huge black stain. In the course of the limbs there were superadditions to and renewals of colour, in the form of markings and blots; there were smudges and alterations in the tints, as of brown and yellow ochre, side by side, crowded together, and but slightly blended. The skin was thus varied and unequal, and though the ensemble is very black, it is broken with dingy shades of red, purple, or green."

This is doubtless an extreme case, but it may emphasise to your minds the fact that more or less pigmentation is usually present. Another point in Jane E—— is of some interest. In the subcutaneous tissues of the nape of the neck were some firm tubercles, the remanet of a large number which had formerly existed in the same region. In two other instances these tubercles have been noticed in the case of Mr. Gaskoin just alluded to, and in one of Mr. Hutchinson, a boy of ten years old, where they were in large numbers in the superficial fascia and the periosteum of the superficial bones, especially over the scapulæ, the spines of the vertebræ, the cartilages of the ribs, the crests of the iliac bones, &c. It appears to me probable that these tubercles are of the same nature as the "rheumatic nodules" described by Drs. Barlow and Warner, and commonly found in association with cardiac disease and rheumatism; they occur in similar situations and tend to disappear spontaneously. In Mr. Gaskoin's case some disappeared in a month, some took much longer; probably, if looked for, they would be found much more frequently than appears now to be the case, as they produce no inconvenience and are rarely conspicuous.

We now come to the most interesting consideration. What is the relation of this atrophic form to the hypertrophic form? Is it a later phase, only that the new tissue has shrunken and produced this condition? This is the usually accepted explanation, and the minute anatomy of such cases as have been examined lend some support to this theory. There has been found a great increase in the connective-tissue bundles, and of the elastic fibres, with diminution of the subcutaneous tissue bundles and fat lobules; and in these contracted cases the skin is directly adherent to the fascia or periosteum. There is narrowing of the vessels, in Schwimmer's case, examined by Babes, from concentric hypertrophy of the media and intima, but the commonest cause seems to be the infiltration of lymphoid cells round the vessels, which lie in the lymph channels, and form a sheath of varying thickness which presses upon the vessel, and this pressure is added to by the contraction of the increased connective-tissue bundles. There is increased pigment in the rete and corium, ectasia of the sweat glands, at first, and ultimately destruction of them, and of the hair and sebaceous follicles. Doubtless the contraction of all this new connective tissue would be calculated to produce the condition we observe in the atrophic stage, and in some cases this probably plays an important part, but it can scarcely account for such cases as that of Jane E——, and for most of the atrophic cases on record, in which the contraction appears to follow too quickly for it to be due to the contraction of newly developed connective tissue. The disease commenced, you remember, with œdema, or, as she called it, "dropsy," limited to the extremities, and the present condition gradually supervened, and was fully developed in less than six months. In the other case the early history is not very clear as to how soon the wasting set in, but there was pitting on pressure at first. In a case of Erasmus Wilson, after great mental anxiety, the skin became dark and swollen, and in a short time contracted; that the swelling was œdema we learn from the condition of the hands and feet, which some months later were swollen. The patient had perfect command of their movements at first, but later they stiffened, and were contracted.

Clearly, then, these cases differ somewhat from the first set, in which there was no pitting, though the difference is one of degree, not of kind; for it is not simple œdema, the pitting being, as Wilson put it, more like that produced by pressing on a skin of lard than on mere dropsical tissue. What, then, is the factor which determines whether atrophy shall set in early or late, or be absent altogether? Mere blocking of the lymph channels will not account for the symptoms, for, as Kaposi justly remarks, we should expect with this the condition of elephantiasis arabum; but there is this difference—in elephantiasis arabum, the trunk afferent vessels are, for the most part, free, while large numbers of the afferent vessels, both venous and lymphatic, are blocked. The result is œdema and overgrowth. In scleroderma large numbers of the terminal afferent vessels are more or less obstructed; and though, no doubt, many veins and lymphatics are obstructed too, the amount of nutrition brought is so much diminished that atrophy, not hypertrophy, results; while in cases such as our first two, occlusion affects a smaller number of afferent vessels, or is less complete, and distension of the tissues results. In short, in my opinion, the condition is one of ischæmia affecting the terminal arterioles, on the one hand, and venous and lymphatic blocking on the other, and according to whether the arterial obstruction is relatively great or small, atrophy or hyperplasia results. This view is, I think, in accordance with the acknowledged anatomical facts, and it will explain how the atrophic stage may be reached with antecedent œdema, but without the conspicuous intervention of the extreme lymph infiltration which characterises the hypertrophic condition; still, it leaves unexplained what was the origin of the process. Hutchinson, Kaposi, Schwimmer, and others seek this in the nervous system. Kaposi and Schwimmer regard it as a central trophoneurosis, and this is probably true to a certain extent for these diffuse symmetrical cases; while for the unilateral cases, especially those which show a distinct nerve distri-

bution, a more local neurosis would accord better with the clinical facts; but even now we have only gone one step further back, for while the nervous system may start a morbid process, and may have influence in localising its cutaneous manifestations, some other factor is necessary to determine the kind of disease that shall ensue. What that other factor is we do not know; probably the idiosyncrasy of the patient, whether congenital or acquired, is one of the most potent influences. In this case our French *confrères*, from its relation to rheumatism, would probably consider that the arthritic disposition was the factor sought for; but, as I have already shown, this is not a satisfactory explanation, for it has already been made responsible for so many varieties of skin eruption that it leaves us much in the same position as before.

There is another point in these cases to which I must allude. Of the four cases before you, three are females and one a male. As it happens, this is the proportion in which, taking a large number of cases, the disease affects the different sexes, and the coincidence will perhaps impress it upon your minds.

Such then, gentlemen, are the history and explanation, as far as I can afford it, of this mysterious disease, which, attacking people in the prime of life who were often previously in good health, too frequently leaves them hopeless cripples and blights their whole future existence. Is there, then, nothing to be done for these unfortunate patients? Yes, something may, though it falls far short of what we should wish. For the hypertrophic cases there is always hope that improvement may occur before new fibrous tissue is completely formed and undergoes its subsequent contraction. The first two cases show that nature itself does much; but we may assist her, not so much directly as indirectly. Good food and protection from changes of temperature are imperative; ferruginous and other tonics, with cod-liver oil, are distinctly beneficial in most cases, and shampooing after Turkish baths, or friction with oily substances appear to be important adjuncts; while some attach importance to galvanisation of the sympathetic. Although it is difficult to appraise the value of these measures in a disease capable of spontaneous improvement, yet as a whole I believe them to be useful, and they are certainly grateful and encouraging to the patient to whom a "do-nothing" treatment is profoundly disheartening. For the atrophic cases the outlook is decidedly gloomy, too often by this time irremediable crippling has resulted before the patient is seen. Priscilla F——s case should encourage us to strive to give relief, though a cure is hopeless, for she had had the disease three years without improvement, when she first came under observation, and now has regained many of the lost movements, and all induration has disappeared. The same line of treatment was pursued as that indicated above, except that she had only the frictions and tonics without either Turkish baths or galvanism. The last agent is much advocated by some observers, but I have not tried it in these cases; for Jane R—— was so evidently improving spontaneously that it would have only been misleading to have used such an agent, while Jane E—— had been treated by galvanism for twelve months before she came here, without benefit. The best proof we can get of the efficacy of any line of treatment is when, after the disease has been quite stationary for some time, improvement ensues on the adoption of a certain measure. This is the case already with Jane E——; so that I think we may fairly credit the means employed with a good share in her improvement. The use of Turkish baths can afford another test of improvement- namely, in the resumption of the secretion of sweat, which is in abeyance when the disease exists in a high degree. Jane R——, for instance, observed spontaneously that sweating had returned in her hands in one of the baths, after being absent for several months. I think, therefore, there is fair ground for assuming that these therapeutic measures do really influence the disease for good, probably by improving the impeded circulation. Of course, arsenic, iodide of potassium, and mercury have been administered over and over again, but there is no evidence that they have been of any benefit; and mercury appears to have been distinctly injurious.

AT the recent annual meeting of the supporters of the Windsor Dispensary and Infirmary a very favourable report was presented, showing a balance in hand. During the past year a new women's ward has been erected, and increased facilities for dealing with accident cases provided.

ABSTRACT OF

Lettsomian Lectures

ON

DISORDERS OF DIGESTION,

THEIR CONSEQUENCES AND TREATMENT.

Delivered at the Medical Society of London on Monday, February 2nd, 1885,

BY T. LAUDER BRUNTON, M.D., F.R.C.P.,
ASSISTANT-PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL.

LECTURE III.

WITH regard to the treatment of disturbances in the digestive function, the first step towards restoring it to health is to remove, if possible, the disturbing causes. Imperfect mastication is one of the commonest causes of disordered digestion. Man is a low-pressure engine, and works almost all his organs considerably under their full power. A healthy stomach can usually digest a good deal more than it is commonly called upon to do. There is, however, a limit to all things, and that limit is more easily reached in some cases than in others. The reserve powers of any function gradually diminish as age increases. If the mind be excited in any way, the movements of mastication are apt to sympathise with the mental excitement. It is evident that, during meals, all ideas of action to be taken by the individual himself should be banished from the mind. Reading anything which interests strongly should not be done during meal-time; and solitary meals are as a rule to be avoided, for the presence of a companion serves to maintain the nervous activity to which reference was made in the first lecture as an important factor in perfect digestion. The condition of the teeth is another cause of imperfect mastication. No teeth at all is far better than a few teeth; an absolutely toothless old man may masticate and enjoy even hard toast, and here the gums may be like the mandibles of a turtle. The nature of the food plays a considerable part in the process of perfect mastication; for if the meat be tough or the bread new proper comminution is impossible, and so digestion is more difficult. The fine subdivision of fatty food is also of great importance in regard to its digestion. The fat of hot mutton is indigestible because it cannot be pulverised, whilst cold fat can. The more minutely we can subdivide the fat the more easily it is digested. Many years ago Professor Hugo Kronecker asked Dr. Brunton: "How should butter be spread in a sandwich? Should the whole of it be put on one slice of bread and the other slice of bread simply put over the top of it, or should the pat of butter be divided into halves and one of them spread on each piece of bread?" The professor answered the question: "The butter should be divided into halves, and one spread on each piece of bread, because in this way the butter is more minutely subdivided, and thus not only gives a more agreeable taste, but is more readily digested." In regard to butchers' meat there are great differences, depending both on the kind of meat used and its condition at the time of cooking. Meat cooked in a state of rigor mortis was tough to eat, but the old Romans used to eat still newer meat; they suffocated their fowls in wine and cooked them forthwith, so that both meat which is perfectly freshly killed, and also meat which has been kept for a sufficient time, are tender. Dr. Brunton thought the taste for "high" meat was an acquired and morbid one. Eating high meat may overtax the antiseptic powers of the gastric juice and bile. The Esquimaux and Icelanders can consume decomposing food to an extraordinary extent without suffering. The effect of keeping may, to a certain extent, be imitated by the application of a vegetable digestive ferment. In the West Indies a tough beefsteak is rendered tender by rubbing it with the juice of a fresh papaw fruit, which contains a ferment, papaine, having an action very much like the trypsin of the pancreas. Bad cooking is another cause of imperfect digestion. Pleasant and repulsive food will act on the stomach through the nerve centres; while the idea of pleasant food will excite

appetite, the very idea of unpleasant food will excite disgust, and even bring on nausea and vomiting. The appearance of the table furniture may also exert an influence on the digestion. That food itself is a moral agent has long been recognised, and has found expression in the proverb, "A hungry man is an angry man." The favour with which Isaac blessed Jacob was augmented by the ingestion of savoury meats. Cookery may not only be a powerful moral agent in regard to individuals, but may be of great service in regenerating a nation. "Schools of cookery for the wives of working men in this country will do more to abolish drinking habits than any number of teetotal associations." A clear-headed clergyman in New York has perceived that dentistry may be a moral agent, and he has insisted on all the people attending his mission chapel keeping their teeth in good condition.[1] Since the clergyman adopted this plan he has had very much less trouble from drunkenness in his congregation. In Switzerland the relation between the consumption of alcohol and the quality of the cookery has recently been investigated. Savoury substances probably stimulate the circulation of the blood in the nervous centres.

Another important question is the kind of food which a person may eat. The appetite is the best guide for the healthy man. As Dr. Austin Flint very sensibly puts it, "the diet should be regulated by the appetite, the palate, and by common sense." The duration of the meal is an important item, and the comfort of digestion at a *table d'hôte* may be safely attributed to the forced slowness of the progress of the meal.

The pleasurable sensation of perfect satisfaction, ease, and quiescence of body and mind should be the criterion of sufficient alimentation. To effect this most agreeable of sensations and conditions—the real elysian satisfaction of the reasonable epicure—timely attention must be paid to the preliminary processes, such as thorough mastication and moderate or slow deglutition.

Many a man has been saved much misery by a weak stomach, which punished its owner by sickness or headache whenever he tried to overburden it, and thus checked his tendency towards excess at the very outset. The late Professor Laycock observed that patients recovering from a severe illness not infrequently have a craving for salt herrings, pork, or ham; but the fact is that these patients really want salt, and if salt be given them in the form of a mixture the appetite is appeased and the harm is avoided which the herring or ham might have caused. The degrees of digestibility of various meats, fruits, vegetables, and drinks were discussed at length. Sour wines are apt to set up gastric catarrh. A single glass of good wine sometimes disagrees, and some of the people who suffer in this manner also have an unpleasant burning feeling in the gullet whilst swallowing the wine, and Dr. Brunton suggests that hyperæsthesia of the mucous membrane may have something to say in the matter. Coffee does not affect the stomach to such an extent as tea. In its preparation, however, a substance called caffeon is produced, and this, along with the caffein which is present in coffee and tea, appears to dilate the abdominal vessels and cause a feeling of fulness in the abdomen, with a tendency to piles in some persons.

Another cause of imperfect indigestion is fatigue. When exhausted, it is far better to get forty winks before dinner than after. Walking or other exercise after a long day's work and prior to dinner, by exhausting the nervous system, was a potent cause of indigestion. Effects somewhat similar to those of fatigue may be produced by depressing or disturbing mental emotions or bodily conditions. Different emotions appear to affect specially, not only different organs like the heart and intestinal canal, but different parts of the digestive apparatus. Thus disgust affects the stomach, causing vomiting; fear is seen, in some of the lower animals, to affect the rectum, causing defecation; compassion affects the small intestine, producing borborygmus; worry and anxiety appear to have a very special influence upon the liver. In treating indigestion due to injurious mental influences, bromide of potassium, either alone or combined with bromide of ammonium, is very useful, both in lessening the sensibility of the nervous system to worry and in procuring sleep; for, as Shakespeare truly says,

> "Sorrow's weight doth heavier grow,
> Through debt that bankrupt sleep doth sorrow owe."

Disorders of the genital organs are apt to give rise to mental depression and to digestive derangements.

[1] The New York Medical Record, Feb. 24th, 1883, p. 224.

The pathology of indigestion and the action of remedies cannot be properly understood unless we constantly bear in mind the intimate relation which exists between the alimentary canal and the rest of the body.

The gastric tonics are chiefly vegetable bitters, and they increase the appetite, lessen flatulence, and tend to diminish discomfort and languor. Nux vomica is one of the most useful of this class, and the great benefit derived from its use is probably due to its stimulating action on the nerve centres, by which the coördination of the digestive processes is rendered more perfect. Carminatives tend to disperse flatulence; the ethers and volatile oils probably act by increasing the movements of the stomach and intestine, and altering them in such a way as to allow the gases they contain to escape upwards or downwards. Charcoal, subnitrate of bismuth, and binoxide of manganese would appear to act largely mechanically; and cases of dyspepsia are reported which have been successfully treated by the administration of fine sand. The ethers and alcohols are closely allied to the carminatives. The difficulty about alcohol is to define its place. There is a great deal of practical truth in the definition of dirt as "matter in the wrong place." In regard to the use of alcohol in dyspepsia, Dr. Brunton thought St. Paul's advice to Timothy was very good: "Drink no longer water, but use a little wine for thy stomach's sake and thine often infirmities." Another important chapter in treatment is the removal of waste products. The regular action of the bowels must be maintained at all cost. Headache from constipation is probably due, in part at least, to poisonous products formed in the intestine and absorbed from it, for Brieger noticed that it was only in the first stages of albuminous decomposition that alkaloids are formed, and afterwards they seemed to disappear. So that prolonged constipation without headache may be explained. The manner in which the salts of Carlsbad are used at the site of their natural origin accounts for the greater benefit derived from them than when they are used at home. The sipping has a powerful influence on the heart, as already pointed out in the first lecture.

One cause of biliousness, which deserves attention, is the alteration in the condition of the bile itself. Biliousness is accompanied by two different conditions of biliary flow. In the one kind the stools are clay-coloured from the absence of bile; in the other, the stools are either normal or are dark-coloured, from excess of bile. Certain bodies of the aromatic series have a powerful action upon the secretion of bile. Salicylate of soda is a powerful hepatic stimulant, increasing greatly the quantity and rendering very fluid the consistence of the bile. Other substances of the aromatic series, especially toluylendiamin, greatly increase the quantity of solids in the bile, so that sometimes the bile, from being viscid and thick, will no longer flow through the biliary capillaries, and jaundice results. A similar action may be exerted by poisons manufactured in the intestines. Mercurials may have an antiseptic action in addition to their other well-known effects. Horse exercise acts in a mechanical manner on the liver, tending to squeeze the bile out of the organ into the intestines; rowing, or its imitation in the gymnasium, may effect the same purpose. The alteratives, though ill-understood as is the manner of their action, must occupy an important place. The acids are probably a means of carrying out nitrogen in the form of ammonia, nitrogen which should normally pass out as urea. Nitro-hydrochloric acid is found to be clinically useful in patients suffering from eructations of sulphuretted hydrogen; it is also useful in oxaluria and depression of spirits. Ammonia and chloride of ammonium have a powerful action on the liver. Ammoniacal salts increase the formation of glycogen. Diuretics are useful in some cases of indigestion. Hot water is thus useful in some cases of gouty dyspepsia. Alkalies increase the diuretic effect, and effervescent citrate or tartrate of potash is useful both as a diuretic and as a local sedative to the stomach in neurotic and gouty gastralgia. By the frequent use of water as a diluent, either alone or with salines, the consequences of indigestion in regard to the lungs, heart, and head may often be averted or remedied. Asthma in gouty subjects is, perhaps, best treated by a mixture of bromide and iodide of potassium, and the addition of a little arsenic is said to increase the effect. Bromide of potassium is frequently useful in cases of intermittent pulse, though Dr. W. Begbie used with success a remedy composed of two grains of powdered rhubarb, ten of subnitrate of bismuth, one and a half of nux vomica, and three of compound cinnamon powder, to be taken before meals, and, if there

be acidity, ten grains of bicarbonate of soda or of magnesia may be added to it. It may be given in water or in a wafer swallowed along with a little water. Giddiness frequently takes the place of headache in persons of middle age suffering from biliousness, and both headache and giddiness are frequently connected with disorders of vision. Bilious headaches with tenderness of the globe of the eye may be relieved by small doses of salicylate of soda, half a grain in an ounce of water being taken every quarter of an hour or half an hour. Considerable attention ought also to be given in confirmed cases of indigestion to a most important method first introduced to notice by Weir Mitchell—namely, massage. A case of most profound emaciation, apparently dependent upon tubercular peritonitis, was narrated by Dr. Brunton in which the effects of massage seemed little short of marvellous. From the hasty sketch given of the disorders of digestion Dr. Brunton thought it would appear that although our knowledge of the subject is still very imperfect, yet a large number of observations have been accumulated which we may hope will, before long, enable us to understand the pathology more fully and to treat these disorders more perfectly.

ON

SOME COMPLICATIONS OF TRACHEOTOMY, WITH ILLUSTRATIVE CASES.

BY ROBERT WILLIAM PARKER, M.R.C.S.,
SURGEON TO THE EAST LONDON HOSPITAL FOR CHILDREN.

(*Concluded from p. 195.*)

3. *Irritative Changes due to the Presence of a Tube.*—In a few cases the mere presence of a tracheotomy tube in the trachea, even when perfect as regards length, shape, and size, appears to give rise to an irritation which is quickly followed by the growth of granulations. A considerable amount of granulations has been found in from four to eight days in cases which have terminated fatally. Such a condition may be suspected if the insertion of the tube appears to cause undue irritation, and especially if its insertion is followed by blood-stained secretion. The use of the feather also causes very considerable irritation, and has to be discontinued. In cases where the granulations about the external wound proliferate with unusual exuberance, such a growth may be suspected within. This peculiarity seems to depend on a hypersensitiveness of the tracheal mucous membrane, and it is an idiosyncrasy which must be taken into account. Minor degrees of this condition are often experienced, some tracheotomised children never reconciling themselves to the cleaning and changing of the tube.

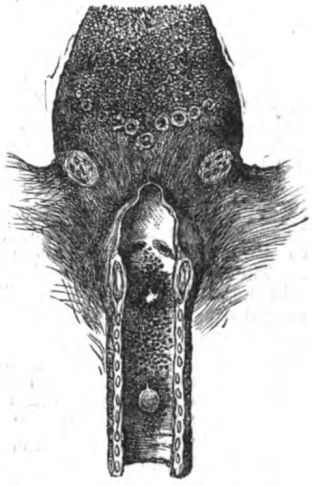
If granulations spring up, the best treatment is the local application of nitrate of silver. A silver probe, after being suitably bent and coated with fused nitrate of silver, is introduced into the tracheal wound, and made to touch as nearly as possible those parts on which the tube has rested. Or a few drops of a thirty-grain solution of nitrate of silver may be allowed to trickle into the trachea, the child sitting upright and inclined slightly backwards, so that the solution may run over the affected portion of the trachea.

The granulations I am now alluding to may occur all round the trachea, and not merely on the anterior wall or at one spot; for they are not due to pressure, but, as before stated, to the presence of a foreign body in an unusually sensitive trachea. I append the drawing of a trachea (see Fig. 5) in which granulations due to this cause were very abundant over the whole track of the tube. There was no sign of ulceration; the granulations occurred within five or six days of the operation. The child appeared to be doing very well, until one night it was suddenly choked after a violent fit of coughing. The autopsy revealed the presence of granulations between the tracheal wall and the tube, which doubtless during life were florid and turgid with blood, and completely filled the space; one currant-like granulation, larger than the rest and attached to a small pedicle, had apparently been driven by the coughing into the tube and completely occluded it.

In the case of warty laryngitis—that is, when there is a natural tendency to the formation of warts—the irritation of a tube leads to the production of minute warts, instead of granulations proper, as seen in Fig. 3, below the tracheal opening. In the case of granulations proper, some difficulty is usually met with in the removal of the tube. At first sight the obvious remedy is the removal of the cause; but an acute obstruction having necessitated the use of the tube, granulations having occurred and actually existing, the difficulty arises of how best to treat them. Such cases all point to the desideratum of tracheotomy without the use of tubes at all. At present, I have not been able to dispense with them; nor do I know of any trustworthy means of gaining the desired objects without tubes; at the same time it is a desideratum I constantly have in mind, and which I recommend to the consideration of my professional brethren.

As to treatment, reference has just been made to the use of nitrate of silver once a day, or once in two days. The alum spray or tannin spray (an ounce of tannic acid glycerine in seven ounces of water) must be used at frequent intervals through the day and night. The tube should be removed for as long as possible, and the silver plug inserted, the patient being meanwhile under direct supervision; for on the removal of the tube, the granulations swell out, and if present in quantity they in time occlude the trachea. Hence in a few instances a child will breathe well for an hour or two, then the tube must be reinserted. The explanation appears to be as follows. The tube by its presence keeps back the granulations, but having been removed, they commence to swell up; possibly also the more laboured breathing (which follows the removal of the tube), by causing congestion, helps them to still further occlude the

FIG. 5.



trachea. Cauterisation and astringents are the best remedies, and are generally successful.

4. *Accidental Conditions.*—Under this heading I shall include two cases, which, though not unique instances, are nevertheless so rarely met with as to require separate consideration. They appear so purely accidental in their incidence that none but the most general precautions can be taken to guard against them.

CASE 6. *Catarrhal Laryngitis; Tracheotomy; Difficulty in removing Tube; Hypersensitiveness of the Trachea; Death in Convulsion fifteen days after removal of Tube; Autopsy; large Granuloma at the seat of cicatrised Wound inside the Trachea.*—Eliza M——, aged two years and a half, was admitted into the hospital under the care of my colleague, Dr. Eustace Smith, on February, 1882. She was one of eight children, of whom one had recently been suffering from quinsy. She had enlarged glands about the neck, secondary to eczema capitis, to which disorder she was very subject. She was a plump, well-nourished child, and well-grown for her age, with no very manifest signs of rickets. On admission she was said to have been hoarse for two days; she had that morning complained of having "a pin in her throat." She had had no discharge from her nose, and there was no illness in the house. Her breathing had become so laboured by the following day that tracheotomy had to be performed by Mr. Battams; the high operation was done; chloroform was administered by Mr. Sanderson, one of the resident officers. No membrane was got up or seen. The child did fairly well; efforts to remove the tube, however,

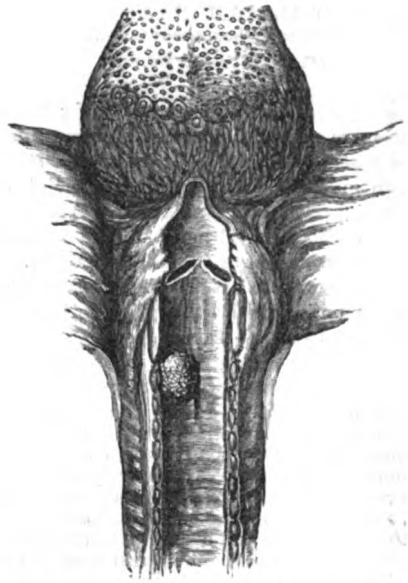
were not successful until March 15th, thirty days after the operation. It was remarked at the operation, as well as subsequently, that the child's trachea was remarkably sensitive; she coughed violently whenever it was necessary to clear the tube or attend to the wound, and one of the difficulties which attended the attempts to remove the tube appeared due to this hypersensitiveness of the tracheal mucous membrane. Finally, the tube was removed, and the external wound gradually closed up. The child breathed fairly well in the day-time, but had attacks of urgent dyspnœa, becoming progressively worse during the nights, with some nights of comparative immunity. The voice was not hoarse. On March 31st, forty-six days after the operation, the child died in a convulsion after an attack of dyspnœa rather worse than usual. The trachea was again opened, but too late to save life.

The autopsy revealed the condition depicted in Fig. 6. "At the site of the old tracheal wound is a highly vascular livid red mass of granulation, more or less pedunculated, projecting into and considerably narrowing the trachea at this point. The ary-epiglottic folds are very œdematous."

In this case the laryngo-tracheal mucous membrane was exceedingly sensitive, and doubtless also somewhat œdematous. Thus breathing was rather more laboured than normal after the tracheal tube had been removed. The granuloma doubtless gradually developed and increased in size, and finally, during an unusually severe paroxysm of laboured breathing, it became extra turgid, and so completely occluded the cricoid opening (which is the narrowest part of the windpipe), and thus killed the child. A fatal termination to a case of tracheotomy from this cause may be regarded as a rare event. Dr. Petel, in his graduation thesis,[1] only collected ten such cases in addition to the one he himself recorded. In three of the cases a second operation was performed with complete success. In one case the child was tracheotomised three times, and had still to wear the cannula. In another case the polypoid granulation was spontaneously coughed up. In three cases death resulted before help could be given. In two cases the condition, which had not given rise to any symptoms, was only discovered at the autopsy, death having taken place from some other cause. In a minor degree, nevertheless, I am inclined to think that such a condition is not very uncommon. There are no *a priori* grounds why granulations should not spring up on the deep surface of the wound as they do on the superficial. On the latter granulations, sometimes very exuberant, are the rule. From a study of the published cases it appears that the granulations have most frequently grown from the upper angle of the wound—that is to say, immediately below the cricoid opening, the point where their presence would be most dangerous. The possibility of such an occurrence has even been urged, but I think the grounds very insufficient, as an argument against the high operation. This condition may be suspected—the patient having previously undergone tracheotomy, the tube having been removed, and the wound being more or less cicatrised—if the breathing again becomes gradually and temporarily embarrassed, the voice generally remaining unaffected. At first this embarrassment will be chiefly obvious at night, when the child is asleep; then during the day-time also. It will be paroxysmal, and vary much in intensity; in the later stages expiration will be as much impeded as inspiration (or more); there will probably be blood-stained expectoration, especially after paroxysmal coughing. It is probable also that the external wound may have exhibited a tendency to exuberant granulations. Given such signs, what is to be done under the circumstances? The surgeon will have to be guided by the intensity of the resulting dyspnœa; if it tends to improve slowly, the use of the alum or tannin spray may be continued; if it tends to become more marked, a second operation will have to be undertaken and an examination of the part made, with a view to the removal (if present) of the granulations by forceps, caustic or otherwise. In his interesting graduation thesis Dr. Carrié[2] says, p. 63:—"In these circumstances, with difficulty [of breathing], recession, noisy breathing during the night, we must not await a first access of suffocation, which may prove fatal, but at once re-open the trachea."

CASE 7. *"Croupy" Cough; urgent Dyspnœa; Tracheotomy; Inability to remove the Cannula; Sudden Death three months later; Autopsy; Web-like Adhesions between the Cords.*—A little boy, eighteen months old, came under observation on account of a "croupy" cough and dyspnœa, which subsequently necessitated tracheotomy. No membrane was got up. At the end of a week attempts to remove the tube were commenced. They were quite unsuccessful, and remained so. The child's general condition was good, and he appeared well in all respects except that he could not get on without his tube. One night he was found dead in bed. No sound had been heard by the night nurse, who had just previously looked at him and found him sleeping comfortably. The bedclothes were quite undisturbed. His eyes were closed, and his features free from any sign of a death-struggle. The autopsy revealed the following condition. The lymphatic glands, tonsils, follicles of the pharynx, and root of the tongue were very much enlarged. On the anterior wall of the œsophagus, opposite the shoulder of the tube, there was an oval diphtheritic patch three-quarters of an inch long, corresponding with a similar condition on the posterior wall of the trachea. Looking into the larynx from above the vocal cords were seen to be much swollen. Looking up the trachea from below there was no visible passage; in fact, immediately above the tube there was a diaphragm of granulating and cicatrising tissue, which had a short, unattached margin opposite the posterior wall of the windpipe and

FIG. 6.



nowhere else. This septum would impede inspiration greatly and expiration altogether. There was great ulceration of the mucous membrane opposite the end of the tube.

5. *Ulceration in the Trachea, due to ill-fitting of the Tube.*—This condition is now of much less frequent occurrence than formerly. M. Roger was the first to draw prominent attention to the subject, and to suggest at once the cause and the remedy.[3] As I have no personal cases to relate, I must summarise M. Roger's views and conclusions. He showed that the complication was more liable to occur in some cases and in some epidemics than in others; but from the anterior wall being most affected, and just at the place corresponding to the lower extremity of the tube, he argued that the chief cause of the ulceration was pressure of the tube, "l'action vulnérante de la canule." This condition is most to be feared when the tube has to be worn for a longer period than usual, but it has been found as early as thirty-six hours after the operation. The ulceration may be only superficial, or it may be deep enough to perforate the trachea; and, as cases are recorded in which the innominate artery has been opened, it will be allowed that this complication is a very formidable one. As symptoms of this form of ulceration, M. Roger gives the following. It is to be suspected if the external wound assumes a sloughy condition, and if the breath and expectoration become fetid, the tube will be blackened, either entirely or in patches,

[1] Des Polypes de la Trachée, survenant après Cicatrisation de la Trachéotomie. Thèse de Paris, 1879, No. 500.

[2] "Contribution à l'Etude des Causes empêchant Ablation définitive de la Canule. Thèse de Paris. 1879, No. 13.

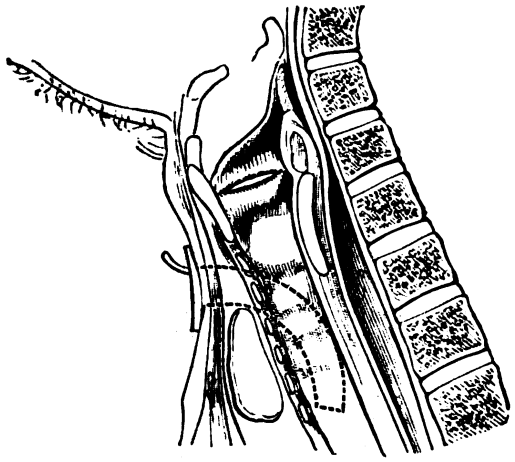
[3] Archives Générales de Médecine, 1859, vol. ii.

and there may be pain or difficulty in swallowing. Most of these symptoms, however, may occur without the presence of ulceration, as I have seen on many occasions. The difficulty of recognising the onset of this ulceration, no less than its dangerous nature, render it incumbent on the surgeon to watch his patient closely on the one hand, and on the other only to use such tubes as are comparatively safe and unlikely to press on the trachea.

M. Roger tried different materials—gutta-percha, india-rubber, flexible ivory; but finally discarded them in favour of silver, recognising that the ulceration depended on the unsuitable shape of the tube, rather than on the fact of its being rigid: "La forme des canules habituellement en usage n'est pas celle qui conviendrait le mieux" (p. 180, op. cit.). After many unsuccessful trials, M. Roger finally adopted Lüer's tube with the movable collar.

While admitting the immense improvement which was thus effected, I am inclined to think that much of the mischief was really due to the quarter-circle shape of the tube itself. A glance at the annexed drawing (Fig. 7), which

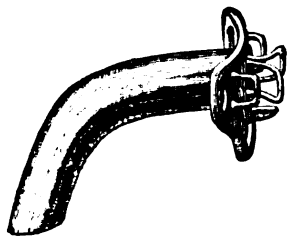
FIG. 7.



Outline figure of the trachea, showing its direction, and also an ordinary tube *in situ*.

represents the trachea in frozen section, will show that such a tube must of necessity press upon the anterior wall of the trachea. With a view to remedy this defect, I suggested some years ago an "angular" tube. An extended use of this tube leads me to think highly of it, and justifies me, I hope, in recommeding its adoption by others. The drawing (Fig. 8) shows how its lower half, by being directed

FIG. 8.



The angular tube.

backwards and downwards, corresponds with the direction of the trachea, and that, however long, it can never press upon it. If this tube be imagined in the trachea in place of the quarter-circle tube, as seen in Fig. 7, the advantage I claim for it will be conceded.

I will conclude by recommending surgeons to be well provided with a variety of sizes; slight differences in length of the tube, in depth from the front opening to the "angle," and in calibre, I believe, often turn the balance one way or another. A tracheotomy tube, like a boot, must fit comfortably, or it cannot be worn without injury. In order to make the inner tube pass the angle, its posterior wall has to be cut away; let me advise that as little as possible be removed. It is impossible to give too much attention to the manufacture of the tubes; all roughnesses and sharp edges must be avoided. Finally, I think it would be an improvement if the interior of the inner tube were polished, for it could be more easily cleaned.

Perhaps the day will come when we shall be able to dispense with tubes altogether; at present I know of no efficient substitute, though, as I have already said, my thoughts are constantly engaged in this direction.

The points in common in the foregoing, widely different, cases were urgent dyspnœa, necessitating operation, and subsequent difficulty in removing the tube; it will be seen on what a variety of causes the latter point may depend, and how important a correct estimate of its real one becomes. Since writing the above, I have operated for the second time on a little boy, and found a mass of granulation tissues blocking up the cricoid ring. In addition there appeared some cicatricial narrowing in the upper part of the trachea. The boy is still under treatment, and I am rather fearful that he will have to continue to wear his tube, until further growth in the trachea—which goes on very rapidly as adolescence approaches—has taken place.

Old Cavendish-street, W.

THE QUESTION OF THE IMPORTANCE OF FLEXIONS AND DISPLACEMENTS OF THE UTERUS.

BY GRAILY HEWITT, M.D., F.R.C.P.,
PROFESSOR OF MIDWIFERY AND DISEASES OF WOMEN, UNIVERSITY COLLEGE; OBSTETRIC PHYSICIAN TO THE COLLEGE.

IN a former paper[1] I offered some remarks on the recent statistics of Vedeler and Herman as bearing on "the question of the importance of flexions and displacements of the uterus." Dr. Herman has since[2] replied, and I hope to be permitted to make some further observations on this subject. Notwithstanding Dr. Herman's objections, I still maintain that these statistics do not give trustworthy evidence as to the actual frequency of flexions of the uterus in really healthy subjects, considering, as I do, that in all probability many of the supposed healthy individuals would have given evidence of presence of symptoms had such been carefully and sufficiently looked for, and for other reasons previously stated. But supposing for the sake of argument we agree to waive the point as to the health of the subjects of the statistics in question, how far do they support the view that flexions are in themselves of no pathological importance?

It has been made a reproach to me that before generalising in the way I have done on the subject of flexions (and displacements) of the uterus I should have proceeded differently, and should have ascertained the frequency of flexions in women generally who are in a state of health. It is easy to make the criticism, but it is not easy to make observations such as would satisfy all requirements in any considerable number on women in a state of health. The statistics which have been put forward by Vedeler and Herman, and which profess to offer the desideratum in question, I have already commented on, and have objected to them for reasons which still appear to me good reasons. But, nevertheless, I consider that they constitute a valuable contribution to the facts necessary for the discussion of the subject. These statistics do not, in my view, invalidate the conclusions I had arrived at as to the importance of flexions and displacements of the uterus. The statistics in question are intended to show that in cases not offering marked symptoms, uterine flexions are common. But supposing this to be correct, it does not follow that severe symptoms may not, or will not, arise in association with further increase, gradual or sudden, in the degree of the flexions and displacement of the uterus. In my recent paper I stated that "the sufferings of which patients complain are of such a kind as to prove that they are directly related to movements of the uterus, to exaggeration of existing flexions, and the like." Flexions of the uterus are in many cases of slow growth, and may for a time, long or short, give rise to few symptoms; but an accident, or a strain, or long-continued over-exertion, may so increase and intensify a previously slight flexion that acute sufferings begin there and then to show themselves. Analysis of cases under my notice has shown the great frequency with

[1] Vide THE LANCET, June, 1884. [2] Ibid., Oct. 1884.

which injury, falls, accidents, &c. were found responsible for the illness from which the patient suffered, as I have shown in the last edition of my work. When such cases come before us it, of course, generally happens that we know nothing for certain as to the state of the uterus before the accident. In some, probably the uterus was in a tolerably normal condition, but it is probable that in most of such cases, and this view is favoured by these recent statistics, the uterus was affected with flexion to a certain degree before the accident, injury, overstrain, or what not, and was therefore more readily and seriously pushed out of its proper place, and more considerably altered in shape, by reason of that existing predisposition. Further, if the previous history of cases of this kind be carefully gone into, it will be found that in many instances facts will be revealed intimating a more or less long-standing disability on the part of the uterus, although the ailment had not been sufficiently severe to call for medical interference, and the subjects of these slight ailments having been reputed to be in health. The transition from health to disease is often slow, and the organs of the body though altered perceptibly to the anatomist from what is considered the true healthy standard may not give evidence of such alterations in the shape of symptoms. Flexions of the uterus are in this category, and in many cases they may attract for this reason no attention. But admitting this to be true, it has still to be considered what is their clinical importace as predisposing to more decided and serious alterations in the uterus? What in fact is the relation subsisting between a patient with flexion, but without suffering, and another who presents a condition of suffering in conjunction with flexion to which are found added congestion, marked derangements of the functions of the uterus of various kinds, &c.? It is plain that this question can only be answered by careful clinical inquiry. One thing is certain, that some women are "weakly" in regard to the uterine organs, and some are comparatively "strong" as the phrase is. There is a predisposition to further and more decided disease in the weakly individuals, and this predisposition is, according to my belief, founded on long experience, a condition of the uterus such as allows it too readily and too easily to assume a more or less flexed shape. It is easy to understand that this kind of predisposition is common, for the number of young women who are really "strong" is not very great.

It is further to be pointed out that when the uterus is flexed, the fundus being directed forwards or backwards, offers a mechanical condition which probably favours to a considerable degree the occurrence of further flexion or the intensification of such flexion. Forces acting downwards, such as severe straining, will necessarily, as it appears to me, cause the free end of the lever, which is also the weightier, under these circumstances, to descend lower in the pelvis. Dr. Berry Hart, in criticising my views on the etiology of flexions, has pointed out that the central part of the uterus not being a fixed point, the effect of such downward pressure will be to cause rather a prolapsus than an increase of flexion. The effect will, no doubt, vary in different cases, and unquestionably a general lowering of the uterus would be a part of such effect (it may even be the chief effect in some instances); but it will probably be conceded that the fundus of the uterus is more free to move forwards or backwards than is the central part of the uterus to move downwards. Therefore, my idea is that, as a general rule, when the uterus is already flexed, a straining force downwards will force the uterus as a whole somewhat lower in the pelvis, but that it will also considerably intensify an existing flexion. In many instances the intensification of the flexion is, as I have repeatedly observed, the main effect resulting.

Flexion of the uterus implies a certain degree of displacement of the organ. When the uterus is abnormally bent backwards, for instance, the fundus is a position of displacement, and the cervix is also more or less displaced. There may be also a displacement of the organ as a whole downwards. There are therefore three possible factors usually combined. (*a*) The bending; (*b*) the anterior or posterior displacement of the fundus, and also to a less degree of the cervical part of the uterus; and (*c*) descent of the uterus as a whole. In different cases there will be a different intensity in each of the three factors in question, and the degree of suffering observed would be expected to vary accordingly. The symptoms resulting are most intense when each of the three factors is present in a marked degree. Mere displacement without flexion is often attended with symptoms, sometimes severe ones, but clinical facts show that taken as a whole versions, for instance, are incomparably less important as regards production of symptoms than those cases in which the uterus is bent. This, to my mind, is one of the great proofs of the importance of the latter condition. In speaking generally, however, of the importance of flexions, I have, as will be gathered from my writings, attributed a due share in regard to the sufferings present to the conditions concomitant with flexions, above categorically described—viz., the factors *b* and *c*. When the uterus, being flexed, retains its ability to move, or is "free to move," there may be no symptoms, and temporary intensification of the flexion may be unattended with such decided symptoms as to induce the seeking medical relief. But when congestion of the uterus, fixation of the organ in its bent shape, and non-capability of restitution after a bending force has been applied, when these events have occurred, decided symptoms will not long be postponed. No doubt there are a multitude of cases in which the condition is one which may be described as being on the borderland; the individual suffers a little, the uterine functions are not well performed, the uterus is more or less flexed. The health improves perhaps, and no further efforts follow; or the individual is overworked or overstrained, the flexion is increased, symptoms occur, and medical advice is sought; or there is a slowly occurring disimprovement, consisting in a very gradual but permanent increase in the degree of the flexion, together with gradual increase in the disturbance of the general health and in the intensity of the local symptoms.

The explanation, therefore, of absence of symptoms in certain cases when flexions are present is that the growth of the flexion has been slow, and secondary effects have not been developed, the uterus gradually accommodating itself to the altered shape. The explanation of the occurrence of symptoms is that there is either a sudden displacement and bending of the uterus, which may or may not have been previously flexed to a certain degree, or that the bending and displacement have become gradually intensified up to such a point that accommodation power is overstepped, and the symptoms slowly but certainly show themselves. Leaving now the question as to the general frequency of flexions and displacements, I proceed to discuss briefly certain other disputed points. The question really at issue in these discussions regarding flexions is the influence exercised by them in bringing about other conditions, termed variously chronic inflammation, congestion, &c., which all recognise as abnormal. These other conditions are, it is admitted, frequently found associated with flexions, and they have to be explained. At the present moment the explanation which has been given of their occurrence, that they are traceable to the presence of flexions and displacements, is contested on various grounds, one being the fact that flexions are frequently found in cases where there is no other alteration. This argument I have already dealt with, but others remain to be considered. The question as to the manner in which "congestion" of the uterus is produced is a vital one in uterine pathology. I was led to form my present opinion on this subject by clinical observations simply and solely. Having so constantly observed that patients suffering from congestion of the uterus were relieved, and the congestion diminished, by altering the position and shape of the uterus, it naturally occurred to me that the congestion must be due to the altered shape and position of the uterus, and the result above described was found to follow so frequently as to leave no doubt in my mind that the congestion was in great part, at least, a mechanical one. Constant observation of the phenomena described, extended over some years, has induced me to consider this account of the causation of congestion of the uterus in the vast majority of cases as accurate. And I am convinced that change of shape of the uterus, such as is involved in the sudden production of a severe flexion, or in the continued and gradual intensification of a previously existing flexion, is precisely what constitutes the principal factor of congestion of the uterus as it is clinically met with. The mere change of shape, occurring in this way, affects the uterine circulation, I believe, by impeding its free course at or near the centre of the bend. In cases of flexion, however, there is always more or less displacement, and not seldom a displacement directly downwards, so that the pressure of the uterus may no doubt interfere with the circulation outside the uterine walls, and in other methods presently to be mentioned. I

repeat, the effect of straightening the flexed uterus in reducing an accompanying congestion has so constantly shown itself in cases under my observation, that flexion and congestion appear to me to stand in positive relation as cause and effect. That such a relation does exist has been admitted by Klob, a pathologist of repute, by Thomas of New York, and others. The well-known power of adjustment in regard to the circulation which other organs possess is doubtless possessed by the uterus. And for this reason, when the uterus has become gradually altered in shape the impediment in the circulation might be slight and the resulting congestion trifling in degree. For this reason flexion of the uterus may be present without marked congestion. But the question is, What will happen when the uterus becomes suddenly and markedly bent to a greater degree than before? Then it is that the phenomena of congestion of a mechanical character would be reasonably expected to be observed. Under such conditions I have repeatedly known it to occur. I say "known," meaning thereby that I have found severe congestion and acute flexion present on examination shortly after accidents, injuries, falls, strains, and the like, whereby the patient has been made suddenly ill. Further, *there* is abundant evidence afforded by the study of chronic cases of flexion that in many instances congestion to a slight degree has been present for a long period, leading eventually to productions of decided symptoms and without occurrence of any severe or sudden accident. I confidently appeal to clinical observation for confirmation of the above statements.

(To be concluded.)

ARTIFICIAL CIRCULATION AS A MEANS OF RESUSCITATION AFTER APPARENT DEATH.

BY CHAS. EGERTON JENNINGS, F.R.C.S.ENG.,
ASSISTANT-SURGEON TO THE CANCER HOSPITAL, ASSISTANT-SURGEON TO THE NORTH-WEST LONDON HOSPITAL.

I. CHLOROFORM POISONING.

THOSE experiments which were published in THE LANCET, Sept. 1st, 1883, being insufficient to demonstrate several points in connexion with transfusion which require elucidation, I have, at the suggestion of Sir Spencer Wells, performed a series of experiments upon dogs at Ghent. As elsewhere stated,[1] the experiments performed in Dr. Pye-Smith's laboratory at Guy's Hospital having indicated that transfusion of blood and the intra-venous injection of saline fluid might be invaluable in certain cases of poisoning, the opportunity seemed favourable for testing the efficacy of the plan I have suggested where poisoning has occurred from the administration of chloroform. To M. Nuel, for the use of his laboratory at Ghent, and to MM. Boddaert van Custem, van Duyse, van Imschoot, Cleays, and Adenaw, for unwearying assistance in this work, my lasting obligations are expressed. I desire particularly to refer to Dr. Ringer's paper in THE LANCET (1883, vol. i., pp. 628-9), "Concerning the Effects of Dilution and Concentration on the Action of Poisons;" and to Dr. B. W. Richardson's paper on "Death from Chloroform," in the *Medical Times and Gazette* (1870, vol. ii., pp. 85-6), and to his communication to the Royal Society in 1865 on the "Possibility of restoring the Life of Warm-blooded Animals," &c., wherein a method of artificial circulation is described.

Experiment 1.—Repetition of the experiments already referred to (q.v.), to demonstrate the method of transfusion of blood and saline fluid, with subsequent repletion of the donor with saline fluid.—July 16th, 1884, 4.30 P.M.: Weight of giver, 47·35 lb. Weight of receiver, 40·74 lb. Hypodermic injection of morphia (⅓ gr.) for each dog. Coma becoming quickly profound in the receiver. $\frac{1}{100}$ gr. atropine was subsequently injected into this animal. Transfusion was established between the right external jugular veins of the dogs, the receiver being simultaneously depleted on the cephalic side of the cannula. The saline fluid employed (temperature 78° F.) contained rather less than half a minim of liquor ammoniæ to each ounce. After the transfusion of blood and saline fluid, the giver was repleted with saline fluid. The entire quantity of saline fluid injected into the dogs was 46·9 oz. Chloroform was the anæsthetic employed. After the experiment the donor had gained 3 oz. 230¾ gr.; since also this dog had vomited considerably after it was first weighed, the injection of saline fluid was still more in excess of the quantity of blood lost by transfusion. The receiver gained 21 oz. 162 gr. Thus it will be seen that in order to demonstrate the important point that blood would not coagulate in the instrument *in transitu*, the transfusion was very abundant, that the test might be a crucial one, and it appeared: (1) That the admixture of saline fluid with blood was capable of rapid and precise regulation; (2) that when the quantity of blood passing through the connecting tube is considerably less than the saline fluid, the former flows as a core, or as strands within the latter medium, the saline fluid being of the lighter specific gravity. Thus protected, the blood is not subjected to friction along the inner surface of the tubing. The transfusion of blood and the quantity of saline fluid injected into the receiver having been so great, it seemed probable that this dog might eventually perish from disorganisation of the corpuscles, and it was decided to repeat the experiment, keeping the injection of the saline fluid within the bounds of safety. And since the amount of saline fluid which can be safely substituted for blood holds a definite ratio to the quantity of blood in the body (the substitution may be carried to the extent of about one-fifth of the blood in man), it is clear that the experiment cannot be pushed so far on a small dog as the injection of saline fluid can be carried with safety in actual practice on human beings. The receiving dog died on July 30th. The autopsy showed that the vessels were exceedingly engorged with fluid blood of a dark colour. All the organs were engorged, especially the kidneys. Examined microscopically the kidneys did not exhibit notable changes. The animal was extremely fat, and there was fatty degeneration of the liver. The costal cartilages were firmly ossified. The dog was an old one, and had lost one eye. The dog which had supplied the blood recovered.

Experiment 2.—July 24th: The dogs each weighed about 12 lb. The receiver was depleted on the distal side of the afferent cannula to the extent of 8¾ oz. Transfusion of blood and saline, followed by repletion of the giver with saline fluid. Forty-four ounces of saline fluid at 85° F., with twenty minims of liquor ammoniæ, were injected into the dogs. This experiment confirmed the preceding; it was performed under mixed narcosis. The apparatus was now washed and taken to pieces; the vein of the giver was ligatured, and the wound closed with sutures. On attempting to tie the vein of the receiver, the animal, having recovered from the anæsthetic with unusual rapidity, struggled. Chloroform was administered with a small supply of air. The dog held its breath for a few moments, suddenly took three or four short inspirations, and (apparently) died instantly. It was proposed to attempt reanimation by means of injecting an ammoniated fluid towards the heart, and depleting from the distal side of the cannula. The apparatus was put together, and the saline fluid which had been prepared for the experiment just performed being exhausted, and there being no hot water at hand, cold distilled water, to which a few drops of liquor ammoniæ had been added, was injected into the jugular vein. The dog was depleted simultaneously. There was no response, and though the time before the operation was commenced was not noted, it was certainly considerable, as will appear from the description which has been given. As a last resort, four minims of liquor ammoniæ were injected by a syringe into the rubber tubing of the syphon, near the cannula, whilst the fluid was flowing. Instantly the heart's action was restored. The heart sounds, as heard by the stethoscope, were exceedingly rapid and forcible. The circulation was re-established; the pulsations of the arteries were very strong and fast; muscular contractions occurred. Artificial respiration was tried, but normal respiration was never resumed. The dog probably died from ammonia poisoning. The experiment with regard to resuscitation after chloroform poisoning was complicated in that it was performed after the dog's blood had been diluted by the previous transfusion of blood and saline fluid, and would not therefore tolerate the further dilution which the method of saline intravenous injection with simultaneous depletion involves. The blood giver recovered perfectly.

Experiment 3.—This was undertaken to test the value of the intravenous injection of an ammoniated saline fluid,

[1] British Medical Journal, April 26th, 1884.

with simultaneous depletion, for chloroform poisoning. The apparatus used was a simple syphon (Fig. 1) charged with saline fluid, containing a small percentage of ammonia. Near the cannula was a T-shaped glass interruption (inverted), the additional limb being surmounted by a short rubber tube and burette clip. This T-tube served not merely the purpose of an air-trap, but, by means of a syringe, a solution of ammonia stronger than that contained in the syphon could be injected into it at pleasure. On July 25th, at 2 P.M., 1/4 gr. of morphia was injected subcutaneously into a dog weighing 14·31 lb. At 2.30 the coma was very profound; 1/10 gr. of atropia injected. At 3.30 chloroform was administered on a towel by Dr. Boddaert very freely, with a small supply of air, till respiration and circulation had ceased. The tongue was then drawn out of the mouth and artificial respiration performed. Respiration and circulation were re-established. Chloroform was given again very freely. The respiration and circulation again stopped. Artificial respiration was performed. Respiration and circulation were again restored. Chloroform was again exhibited. The circulation and respiration ceased, and could not be restored by the performance of artificial respiration. The right external jugular vein was now exposed and grasped with a Wells's forceps at a point corresponding to the centre of the incision. The cannula of the syphon was inserted, by the help of a phlebotome, into the vein on the cardiac side of the forceps. The cannula was secured in its place within the vein by the application of a cannula pin and waxed ligature (Fig. 2), that it should not slip. The vein was opened on the distal side of the forceps. The quantity of blood drawn was about 8¾ oz. (besides a good deal wasted), and the quantity of the saline fluid injected was about 21 oz. at 90° F., containing 10½ minims of liquor ammoniæ. One minim and a half of liquor ammoniæ was also injected by the syringe. The intravenous injection and depletion were quickly followed by restoration of the circulation. Artificial respiration was now sedulously performed, and reanimation became perfect. The dog gained by the experiment about one-third of a pound in weight. This animal completely recovered. Since the injection and depletion appeared to have been carried further than necessary, it was decided to repeat the experiment, and to

FIG. 1.

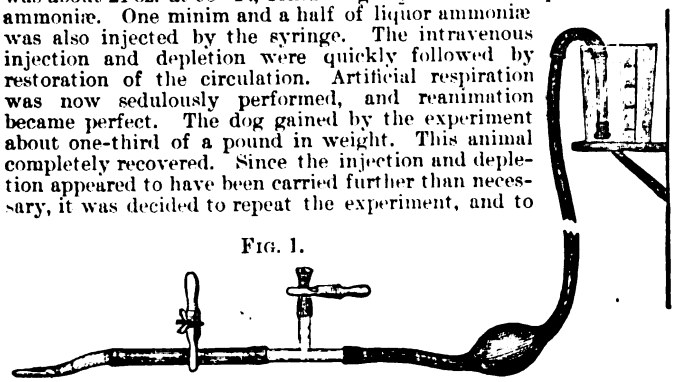


FIG. 2.

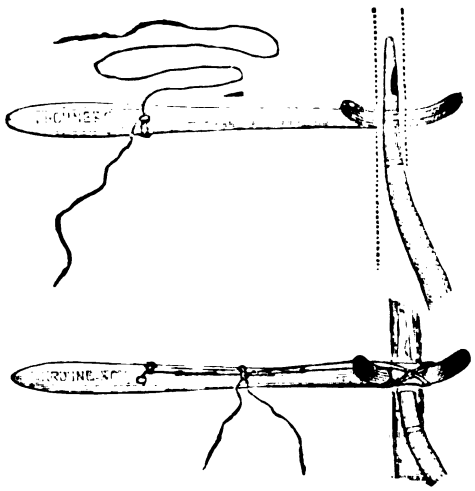

draw a little blood after the intravenous injection had been commenced.

Experiment 4.—July 25th: A black-and-tan dog; weight, 13.1 lb. 2 P.M.: Hypodermic injection of morphia, 1/4 gr. 2.30: Atropia, 1/10 gr. At about 5 P.M. the dog was poisoned with chloroform, and after the circulation and respiration had ceased, artificial respiration was ineffectually tried. After opening the external jugular vein with the phlebotome, the cannula, first entering between the vein and its sheath, was withdrawn. Blood escaped from the aperture in the vein, and a convulsion occurred. The aperture was now grasped with forceps, and the cannula inserted into the vein on its cardiac side. Ammoniated saline fluid was injected into the vein, but there was no return of animation. Depletion on the distal side of the cannula was tried, and the blood, which hardly flowed at first, was of a dark colour and tarry consistence. More saline fluid was injected, and three minims of liquor ammoniæ by the syringe. No signs of reanimation appeared. Artificial circulation was carefully performed, and altogether 23 oz. of saline fluid were injected. The quantity of blood drawn was not measured. On examining the heart, post mortem, its cavities were greatly distended with coagulated blood. It was resolved to repeat the experiment, but to deplete freely in the first instance, in order to relieve the heart and cerebral vessels of all engorgement.

Experiment 5.—July 27th: Weight of dog 11 lb. 3.15 P.M.: Injection of morphia, 1 gr. At 3.45 chloroform was freely administered on a towel with a small supply of air. The anæsthetic was exhibited for about a quarter of an hour, the respiration becoming shallower and fewer in number, and the pulse feebler towards the expiration of that period. At 4.1 the respiration ceased entirely. At 4.2 20 sec. the femoral pulses, which Dr. van Duyse and myself had been carefully feeling, ceased. The tongue was now drawn out forcibly with artery forceps, and artificial respiration was performed. Signs of animation not appearing, the operation was begun. A cannula was introduced as quickly as possible into the right external jugular vein, and tied therein. The dog was depleted on the distal side of the cannula, but the blood at first ran slowly and was of a very dark colour. At 4.5 i.e., 2 min. 40 sec. after the heart had ceased to beat—the injection of 8 oz. 7 dr. of saline fluid at 90° F. with about 4 minims of liquor ammoniæ was commenced. Artificial respiration was persisted with. The flow of the blood became freer, and of a brighter colour. Return of pulsation in the arteries was noticed at 4.10 precisely. Therefore the pulsations had been absent during a period of 7 min. 40 sec. The pulsations were now so forcible that it was feared a poisonous dose of liquor ammoniæ had been injected, but such was not the case. At about 4.30, after the experiment was concluded, the dog on being released ran about briskly. The amount of blood lost by depletion was not measured accurately, some being spilled. It probably was between 6 and 8 oz. 5 P.M.: It was noticed that whilst the dog walked about, curious tetanic contractions of the muscles of the extremities occurred. This point is of importance, for it has been shown that the injection of ammonia into the veins, in a toxic dose, causes tetanic spasms, which cannot be distinguished from those produced by strychnia.[2] This animal recovered satisfactorily.

Experiment 6.—July 27th, 3.15 P.M.: One grain of morphia was injected subcutaneously into a dog weighing 16·5 lb. The administration of chloroform was commenced at 6.15. The pulse became intermittent at about 6.34, and ceased entirely at 6.34 30 sec. The respiration ceased at the same time as the pulse, and could not be restored by artificial respiration, the tongue having been drawn out. Depletion with the injection of an ammoniated saline fluid (34¼ oz.) was performed at 6.38 i.e., three minutes and a half after apparent death. No signs of animation ever appeared. Probably the operation was begun too late after the cessation of the pulse. Further, at the commencement of the infusion the flow of blood was arrested by a coagulum which formed at the aperture made in the vein on the distal side of the cannula. So that what occurred in Experiment 4 took place here also—viz., that the heart, already paralysed by the chloroform, was distended by the infusion, which was in excess of the depletion. This hypothesis was supported by an examination of the heart and lungs, which were found to be enormously engorged. The quantity of blood lost—but not at the outset—was great; but, as already intimated, not so great as the quantity of fluid injected.

Experiment 7.—July 28th, 10.50 A.M.: One grain of morphia was injected into a dog, which weighed 18 lb. Chloroform was administered at 11.30. The pulse became irregular at 11.36, and ceased just before the respiration at 11.40. After the tongue had been withdrawn by artery forceps, and after artificial respiration had been ineffectually

[2] Richardson, Cause of the Coagulation of the Blood, p. 440.

tried, the right external jugular vein was exposed and grasped with forceps. The animal was bled on the distal side of the forceps and a cannula was inserted into the vein on the proximal side. At first it seemed doubtful whether the cannula was properly inserted within the vein; it was therefore withdrawn and inserted in the left external jugular vein. The depletion and injection of nearly 30 oz. of saline fluid at 100° F., with 15 minims of liquor ammoniæ, were commenced at 11.43—i.e., three minutes after apparent death. Four minims of liquor ammoniæ were injected later on by means of the syringe. Artificial respiration was performed concurrently with the maintenance of the circulation; but pulsation not returning, the region of the fauces and larynx was inspected. It was noticed that comparatively little air entered the lungs during their expansion, owing to the fact that the epiglottis, which was flaccid, was drawn down like a valve over the superior orifice of the larynx. The epiglottis was drawn forwards with another artery forceps, and in a few seconds, at 11.55—i.e., fifteen minutes after apparent death—forcible pulsations were detected in the femoral arteries. Contractions of the muscles of the jaws occurred, and also of those of the extremities. The mouth being closed, and the forceps which grasped the epiglottis having been necessarily removed, the indication seemed to be tracheotomy, which was at once performed. But the action of the heart suddenly stopped, and life departed. An autopsy showed that the heart was distended with fluid blood, save a small coagulum on the mitral and tricuspid valves. The vessels were engorged. This report justifies the belief that had tracheotomy been performed simultaneously with the injection and depletion, or, what amounts to the same thing, had the epiglottis been drawn forwards at the onset, life would have been restored. As it was, the artificial respiration was only effectually carried out some fourteen minutes after apparent death, and after the blood had been too diluted to perform satisfactorily its functions. In such a case, transfusion of blood might meet the difficulty.[3]

(To be concluded.)

CASE OF

LYMPHADENOSIS (HODGKIN'S DISEASE), WITH MULTIPLE GROWTHS FROM THE DURA MATER.

BY C. W. SUCKLING, M.D. LOND., M.R.C.P.,
PHYSICIAN TO THE QUEEN'S HOSPITAL, BIRMINGHAM.

J. O——, a man aged nineteen, was admitted into the Queen's Hospital on the 22nd of November last, complaining of pain in the head and giddiness. The patient said he had been ill for three weeks, suffering greatly from pain in the head: it was not constant, but the intermissions were very brief. The pain was always much worse at night, being chiefly localised at the back of the head. For the fortnight previous to admission he found that he saw things double unless he closed one eye. He had a good deal to do with lead in his work, being a galvaniser; he had never had syphilis and had not been a drinker. There was no family history of importance. Up to four days from the date of admission the patient was able to walk about, but he then had severe vertigo, everything appearing to move round him. On admission, the patient was found to be emaciated and markedly anæmic; the facial expression denoted pain. There was internal strabismus of the left eye and diplopia, showing paralysis of the left sixth nerve. He complained of severe pain in the head, especially at the back, and tenderness on percusssion was found all over the skull. The lips and teeth were covered with sordes, the tongue being covered with a thick brown fur. There were anorexia and great thirst, with constipation. The glands in the neck and groin were observed to be very easily felt, but they were not much enlarged. The spleen and liver were also found to be enlarged. The reflexes were normal, sensation also was unaffected. The patient could scarcely stand, the gait being very staggering; but the staggering was not in any definite direction. The pupils were equal and responded normally, but were rather dilated. There was no optic neuritis or any marked change in either fundus, but the veins were noted to be very large and tortuous.

[3] Vide infra, Experiment 15.

Nov. 28th.—The pain in the head is less in the morning, but the patient cannot sleep for it at night. The blood was examined, and the white corpuscles were found to be small and increased in number, but not to any considerable extent, certainly it was not leucocythæmic blood.—30th: At 12 P.M. the patient began to breathe rapidly; the temperature went up to 104°. Severe pain in the head was complained of. He became comatose, and died at 2 P.M. The temperature varied between 98° and 101° F. during the time he was under observation; the pulse was soft, dicrotous, and rapid throughout.

Autopsy.—Hypostasis and rigor mortis were slight. On removing the calvaria, the dura mater was seen, with a soft pulpy tissue of reddish colour, growing in scattered patches over the outer surface; these growths had eroded small corresponding cavities in the bone above. When the dura mater was stripped off the base of the skull, similar growths were found growing from the outer surface of the membrane; one growth, polypoid in form, projected into the lateral sinus of each side opposite the inferior angle of the parietal bone. Another growth filled the sphenoidal fissure of each side, embracing the nerves running through the foramen, thus accounting for the paralysis of the sixth nerve. The lungs and heart were normal; there was no enlargement of the thymus or of the lymphatic glands in the thorax. On opening the abdomen, the intestines were observed to be dotted all over with white spots as large as hemp-seed; these were the solitary glands. Peyer's patches were very large and distinct, and most plainly seen through the peritoneal coat of the intestine; the cæcum especially was covered with white spots thickly crowded together. On section of the patches no trace of caseation or congestion could be found; they were of a white colour. The mesenteric glands were as large as pigeons' eggs, pale and firm. The spleen weighed 24½ oz., was uniformly enlarged, dark-coloured, and soft. The Malpighian bodies were easily seen with the naked eye; they presented trabeculæ radiating from them in a stellate manner. The liver weighed 7 lb., was uniformly enlarged, the lobules being very large and pale; it was easily friable. The kidneys together weighed 10½ oz.; in the cortex of the left one there was a body composed of whitish firm tissue the size of an orange-pip.

The above case is exceedingly interesting and instructive. Growths from the dura mater are certainly rare in this disease, and the prominence of the cerebral symptoms with the very moderate enlargement of the lymphatic glands obscured the diagnosis. The following symptoms suggested the diagnosis of cerebral tumour: Vertigo, pain in the head, paralysis of the sixth nerve, diplopia, and staggering. The staggering was not in any definite direction, and did not enable us to totalise any mischief in the cerebellum, although the pain was very marked at the back of the head. The absence of optic neuritis is probably accounted for by the fact that the growths were on the outer surface of the dura mater, and had eroded cavities in the bone in which they lay; thus not encroaching to any extent upon the brain space. It was thought that the slight enlargement of the glands of the neck and the cerebral symptoms might be due to syphilis, and this was supported by the nocturnal exacerbations of the pain, which were very marked. But the patient positively denied having had a chancre, and iodide of potassium did no good. The enlargement of the spleen suggested leucocythæmia; and the blood was examined, showing only a slight increase in the number of the white corpuscles. The marked predominance of the cerebral symptoms and the absence of any considerable enlargement of the lymphatic glands led us away from the diagnosis of lymphadenosis. The disease in this case was manifested especially in the spleen, intestines, liver, and dura mater. Histologically the growths from the dura mater were of a lympho-sarcomatous structure, consisting of a delicate reticulum, the meshes of which were filled with leucocytes.

ROYAL SOUTH HANTS INFIRMARY.—The yearly meeting of the subscribers to this institution was held on the 27th ult., when the forty-sixth annual report was read. The number of in-patients treated during 1884 was 993, and of out-patients, exclusive of dental cases, 3017. The total income of the infirmary during the year was £4033, and the expenses amounted to £4227. A formal resolution, as brought forward for a year or two past, that the post of assistant house-surgeon be not filled for another twelve months, was carried, with one dissentient.

PERFORATING BULLET WOUND OF ABDOMEN.

NOTES OF THE CASE OF INSPECTOR SIMMONS, ESSEX COUNTY CONSTABULARY.

BY ALFRED WRIGHT, M.R.C.S., L.S.A.,
SURGEON K DIVISION METROPOLITAN POLICE.

THIS officer, whilst on duty, met three suspicious characters on the road three miles from Romford, and, thinking they were contemplating burglary (a surmise justified by the subsequent finding of burglarious implements, which the fellows threw away on being chased) challenged them, and was shot by one of the men at a distance of a few feet. The officer, struck by the ball in the abdomen, staggered but did not fall, and pluckily ran after the fellows for half a mile; and, though feeling faint, afterwards was able to walk to the nearest police-station, two miles farther on; an astonishing circumstance, considering the severity of the injuries. When first seen by me, at 7 P.M., about two hours after the receipt of the injury, there was not much shock, the countenance was not anxious, and the patient had not vomited. There was a small circular wound, evidently made by a bullet, two inches and a half below the umbilicus, and one inch and a half to the left of the median line. There had been but slight hæmorrhage. A catheter being passed drew off half a pint of clear urine. It was at this time hoped that the ball might possibly not have reached the abdominal cavity; for, though it could not be felt in the abdominal wall, it might easily be missed, as the patient was a stout and muscular subject, and of course the probe was but sparingly employed. One-third of a grain of hydrochlorate of morphia was administered hypodermically, hot bottles applied to the feet, the wound was closed by a piece of lint and collodion, and ice was given to suck to relieve thirst, which was great. During the night the doubt as to the intestine being injured was solved by the patient vomiting a large quantity of dark fluid, a specimen of which examined microscopically showed altered blood-corpuscles in abundance. Temperature 99°; pulse 100. The morphia was repeated during the night, but there was no sleep. The patient complained of severe thirst, a good deal of abdominal pain, and had vomited repeatedly and extensively.

Jan. 21st.—9 A.M.: A little tenderness round the wound; no general tenderness of abdomen. Temperature 99°; pulse 110. 1 P.M.: More vomiting of coffee-ground fluid; oozing of similar fluid and flatus from the wound. 8 P.M.: Seen by Mr. Sydney Jones. A counter-opening made an inch and a half below the wound, and a drainage-tube introduced, to allow the escape of fluid, which was beginning to bag in the abdominal wall. No more vomiting since the morning; abdomen slightly tender and tympanitic. Temperature 101·3°; pulse 115; spirits good. The patient was kept well under the influence of morphia injected subcutaneously, and nothing was allowed by the mouth except ice sparingly. 22nd: Restless night; tormented by intense thirst. Temperature 101·3°; pulse 120; respiration 52; more tympanites and more abdominal tenderness; no vomiting; a good deal of dark fluid (fæcal) discharge from the drainage-tube. 6 P.M.: Seen again by Mr. Jones. Condition much the same, but appears weaker. Linseed-meal poultice applied to the abdomen.—23rd: Slept fairly during the night. Temperature 101·3°; pulse 128, weaker; respiration 50. No vomiting. Four ounces of peptonised beef-tea with half an ounce of brandy were administered per rectum, morphia being continued hypodermically. 1 P.M.: The patient turned suddenly livid, with great dyspnœa and cold skin. Ordered brandy-and-water in quantities of a teaspoonful, and enema of beef-tea and brandy repeated. 6 P.M.: Says he feels better; circulation is restored, but the pulse (130) is evidently much weaker; temperature 101°; more tympanites and more general abdominal tenderness. Brand's essence of beef was given by the mouth. 11.30 P.M.: Pulse 138, very feeble; a good deal of abdominal pain; more tympanites; free discharge of flatus and fluid from the tube. Deposition taken.—24th: Gradually sinking during the night. The patient died at 11 A.M.

Autopsy, twenty-four hours after death.—Sanguineous oozing from nose and mouth; great distension of abdomen. Considerable extravasation in fascia and substance of abdominal muscles. Small circular wound through peritoneum; intense congestion of omentum and peritoneal covering of whole of small intestine. A good deal of soft lymph effused, but no extravasation in peritoneal cavity; small intestine uninjured. Wound a quarter of an inch in diameter in front of descending colon, eighteen inches from rectum, the wound being plugged by a fragment of clothing; a corresponding wound three inches lower down in posterior wall of gut. Much extravasation in areolar tissue between colon and sacrum, and in quadratus lumborum muscle; the bullet (weighing two drachms) sticking in centre of sacrum to the extent of a quarter of an inch. Lungs much congested posteriorly; other organs healthy.

Romford.

ABORTION, PHLEGMASIA DOLENS, AND SEPTICÆMIA.

BY E. L. DIXON, M.D., M.R.C.P.,
HONORARY MEDICAL OFFICER TO THE PRESTON AND COUNTY OF LANCASTER ROYAL INFIRMARY.

A SHOPKEEPER'S wife, aged thirty-six, was seen by me for the first time on Sept. 8th last. She had been married three years and a half, had had four abortions (before this), and no living child. When three months pregnant she, apparently from fright, was seized with uterine hæmorrhage, which had continued almost up to the time of my seeing her, but had then entirely ceased. Five days before, a solid substance of some size had been expelled, but had not been examined. Three days before, two or three small black fragments of the size of marbles, and of offensive smell, had also been passed. The day before she had been seized with shivering, and the left leg had begun to swell and be very painful. During one or two of her previous pregnancies it had also swollen. The leg from the hip to the toes was hot and much swollen, and pitted on pressure; the skin was very red in large patches below the knee; the veins about the hip were very marked; and the thigh in the course of the femoral was very tender but not hard. The uterus was slightly enlarged, and the os rather patulous; there was no offensive or other discharge. She had had alarming attacks of fainting during the day; the pulse was very rapid and the temperature high; there had also been retention of urine for many hours.

Sept. 14th.—She has continued very ill. One evening she had a violent rigor, and the temperature went up to 105·2°, and it has always been very high; the pulse has been rapid; there have been distressing vomiting and occasional profuse diarrhœa, and once or twice a mouthful of blood has been expectorated. She has been taking quinine in four-grain doses up to tinnitus aurium, when it was reduced to half the quantity. Hypodermic injections of morphia have been given to relieve pain and procure sleep, and also morphia and atropine pills, unless the purging was profuse, when the atropine was omitted. Her principal food has been iced milk, of which she has taken large quantities; alcohol in every shape has produced vomiting. A vulvar gland (of Bartholinus?) has become enlarged, hard, and painful. Once or twice there has been a very trifling discharge on the napkin applied to the vulva, which has been thought slightly offensive. The symptoms were so alarming that, although on passing my finger into the os I could feel nothing, and the end of it did not smell, I determined to thoroughly explore the uterine cavity, and for this purpose passed in a large sea-tangle tent.

15th.—I thought I reached something with the end of my finger in the uterus, which I washed out with carbolic lotion (1 in 20), afterwards introducing another tent.

The following day the cervix was found fully dilated, and (without an anæsthetic) I succeeded in hooking the finger over and withdrawing a foreign substance, which proved on examination to be a piece of putrid placenta about the size of a damson. Beyond its place of attachment the cavity wall of the uterus quite up to the fundus was perfectly smooth. A carbolic lotion (1 in 40) was now injected into the womb daily until the 19th, when the os had almost closed; there was no discharge of any kind, and the painful enlargement of the vulvar gland had disappeared.

The patient began rapidly to improve after the uterus had been emptied, the temperature fell, and in a week was

normal, and the pulse diminished in frequency. A state of gastro-enteric catarrh, as evidenced by a glazed tongue, vomiting of almost everything but iced milk, and occasional diarrhœa, continued, however, for some time. The right leg became also œdematous below the knee, but was not painful and was soon better. The swelling of the left leg also gradually disappeared.

The interesting point in this case is the retention of a small portion of decomposing placenta within the uterus with such trifling local indications of the existence of the source of infection. The patient was, however, the subject of septicæmia in a very alarming form; and, even at the risk of finding nothing, it seemed desirable to dilate and explore the uterus. This was done not a moment too soon; indeed, it had better have been done earlier, for the poisonous dose absorbed was quite sufficient to make the convalescence somewhat protracted. Bismuth with laudanum seemed most useful in combating the gastro-entérite.

Preston.

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas at mortuorum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.* lib. iv. Proœmium.

GUY'S HOSPITAL.

EIGHT CASES OF CATARACT OPERATIONS IN AGED PATIENTS; CURE.

(Under the care of Mr. HIGGENS.)

These cases of cataract, all of which occurred in patients of the age of eighty or above, are instances of the successful performance of an important surgical operation at a period of life when the surgeon is, as a rule, unwilling to operate except for emergencies. Although the reparative power of the cornea is impaired before the age to which these patients had attained, still in properly selected subjects, as has been recorded by Mr. Higgens, the operation of extraction may be most successful.

CASE 1.—Minto G——, aged eighty, was admitted on June 14th, 1875. Cataract in both eyes; left eye has been quite blind nine years. Extraction by oblique corneal section downwards, and removal of a small piece of iris performed in left eye.—July 17th: Vision = $\frac{2}{6}$ with + 3.

CASE 2.—Judith S——, aged eighty, was admitted on Oct. 9th, 1876. Cataract in both eyes; that in right eye most advanced. Extraction by small flap section downwards, associated with iridectomy, performed in right eye; no anæsthetic was administered.—Nov. 9th: Reads Snellen $\frac{1}{2}$ with + 2½. Vision = $\frac{2}{6}$ with + 3.

CASE 3.—Grace H——, aged eighty-two, was admitted on July 22nd, 1878. Cataract of both eyes; most advanced in right. Extraction by small flap section upwards, and iridectomy performed in left eye.—Aug. 26th: Reads Snellen $\frac{1}{2}$ with + 16 D. Vision = $\frac{6}{12}$ with + 12 D.

CASE 4.—*Esther* A——, aged eighty-eight, was admitted 20th Oct. 20th, 1879. Mature cataract in both eyes; extraction by small flap upwards, and iridectomy in right eye.—Nov. 17th: Could tell the time on a watch with + 13 D.

CASE 5.—William B——, aged eighty-four, was admitted on June 7th, 1880. Cataract in both eyes; right worst. Extraction in right, small flap upwards, with iridectomy.—June 12th: Reads Snellen 1·25 with + 16 D. Vision = $\frac{6}{60}$ with + 13 D.

CASE 6.—Phœbe C——, aged eighty, was admitted on June 22nd, 1883. Cataract in both eyes; extraction in left by small flap downwards, with iridectomy. Severe iritis ensued. On Dec. 10th the iritis had subsided, but the pupil was entirely blocked.—March 10th, 1884: A needle for section for opaque capsule performed.—24th: Reads J. 8 with + 16 D. Vision = $\frac{6}{12}$ with + 12 D.

CASE 7.—Lucy J——, aged eighty, was admitted on Jan. 21st, 1884. Cataract in both eyes. Extraction performed in both by small flap section upwards, with iridectomy.—Feb. 20th: Both eyes could tell the time on a watch with + 16 D.

CASE 8.—William T——, aged eighty, was admitted on Jan. 28th, 1884. Extraction by small flap upwards, and iridectomy in right eye.—Feb. 18th: Tells time on a watch with + 16 D.

ST. SAVIOUR'S INFIRMARY, NEWINGTON.

CASE OF SWORD SWALLOWING; DEATH FROM INJURY TO THE ŒSOPHAGUS; NECROPSY; REMARKS.

(Under the care of CHARLES GROSS, M.B., B.S.Lond., F.R.C.S., Medical Superintendent.)

THE interesting case which Mr. Gross describes is certainly most uncommon, there being few cases on record where the practice of sword swallowing has led to the death of the performer. Dr. Parkes described a case[1] where the man, aged twenty-three, passed the sword through the anterior wall of the œsophagus into the pericardium, the patient dying from acute pericarditis a few hours afterwards.

Reuben S——, aged thirty years, by trade a painter, was admitted into the infirmary on Jan. 17th, 1885. He stated he was in the habit of conjuring and sword swallowing in various public-houses. On Jan. 15th, two days before admission, he was performing at a public-house in Leather-lane, when on pushing a sword down his throat it hurt him far more than usual, and on withdrawing it he spat a little blood. Pain, with difficulty in swallowing, quickly came on, and feeling very ill and uncomfortable he was obliged to return to his lodgings. Becoming gradually worse, he procured admission to the infirmary. On admission he seemed very ill and in pain all over, but especially in the throat and down the gullet, much intensified in his efforts to swallow. The front of the neck was swollen and tender, the breathing shallow and hurried, and he kept spitting glairy mucus unstained with blood. There was nothing abnormal to be seen on looking down the throat. He was quite sensible and gave an account of the occurrence as above; he also stated that he thought the sword he had used on the last occasion had some roughness at its edge; that the performance always hurt him a little, and that he preferred to swallow a smooth whip-handle rather than a sword. He was put to bed, hot fomentations applied to the neck, and milk and fluid diet ordered. He became gradually worse, the neck swelled up more, pain and difficulty in swallowing increased; he eventually became delirious, and died suddenly at 7 P.M. on Jan. 20th, three days after admission.

Autopsy, seventy-two hours after death.—Body, that of a well-nourished, healthy-looking man, well covered with fat. No external marks of violence. Front of neck still somewhat swollen. The heart was large and flabby, and nearly empty. The lungs were slightly congested and œdematous; there was evidence of old pleurisy on the lower lobe of the left lung. The stomach was quite healthy and showed nothing abnormal. The œsophagus, from its commencement to within one inch from the stomach, was somewhat dilated, with its walls much thickened. Its mucous membrane was thickened, tough, and smooth, whitish in colour, resembling the internal coat of the aorta. The outermost coat and surrounding tissues were infiltrated with pus, constituting, in fact, a diffused abscess from the back of the pharynx to the diaphragm. There was no sign of any perforating wound, and only a slight patch of excoriation at the upper and posterior part. Below the bifurcation of the trachea the left vagus nerve ran through the abscess. The other organs, including the brain, were healthy, but full of blood.

Remarks.—The condition described was undoubtedly due to the irritation of the parts by the constant passage of a hard solid body, such as a sword or whip-handle, and had probably been coming on for some time; certainly longer than the five days between the last performance and his death. As he himself stated that lately it had pained him "more than usual," some slight inflammation most likely was set up some time ago, and gradually culminated in the formation of an abscess. The stomach was in no way affected. Probably the sword was not pushed so far, but stopped at the natural narrowing, where the gullet traverses the diaphragm. The immediate cause of death was syncope. I have not been able to procure, nor have I seen, the sword with which this man performed, but I have been favoured by a visit from two sword swallowers, who were attracted

[1] Trans. Path. Soc., 1848-49.

to me by reading the account of my patient's death in the newspapers, and who were anxious for an opinion as to the peculiar dangers to which they were exposed. The swords they use are 21½ in. long in the blade, 1¼ in. broad, tapering to 1 in., straight, heavy, thick, smooth, with well rounded edges and point, similar to those carried by the "pompiers" in Paris. The longest they perform with is 27 in. in length. For my edification they gave a demonstration of the feat. Straightening the passage by well elevating the chin, then putting the point of the sword well to the back of the throat, with one thrust they pushed it down as far as the hilt. With the shorter swords they could bend the body forward from the loins and withdraw the sword whilst in that position. They both acknowledged that they frequently hurt themselves, and one of them had been an in-patient at St. Thomas's Hospital in consequence of an injury to the œsophagus.

The man referred to was under the care of Mr. Francis Mason, and we are indebted to him for an account of the case. The patient, a man aged nineteen, was admitted on June 16th, and remained under treatment eleven days. Two days before admission he was performing in public, and had passed the sword down the œsophagus to within two inches from the hilt. He made signs to a bystander to pull it out, but, instead of doing so, he forced it down. The patient vomited two hours afterwards, and was obliged to go to bed, where he was only able to lie on the right side. When examined, he complained of great pain, referred mainly to the centre of the sternum and upper part of the abdomen. The pain was increased by attempts to swallow and by deep breathing; the abdomen was slightly tender, but not distended. Respiration 30; pulse 84.

June 18th.—There was no pain; he still lies on the right side. Respiration less painful; pulse 94.

20th.—Pulse 84; respiration 26.

21st.—Slight crepitation noticed at the left apex.

23rd.—Still complaining of pain, and there was occasional sensation of sickness and of heaviness after food. He was only allowed ice at first and then fluids, the diet being carefully regulated. The temperature on the evening of admission was 101·6°; on the following morning 101·2°; and for the next week there was a difference of from one to two degrees between the morning and evening temperatures, the highest evening temperature being 101·8° and the lowest morning temperature 99·4°.

In this case it would appear that there was injury to the mucous coat of the lower part of the œsophagus, and possibly to the stomach itself; whilst in the case under the care of Mr. Gross the mischief, as he says, appears to have commenced before the date of supposed injury.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.

MULTIPLE RENAL CALCULI AND PYO-NEPHROSIS; AUTOPSY; REMARKS.

(Under the care of Dr. MILLINGTON.)

FOR the notes of the following case we are indebted to Dr. Dingley:—

Calculi in the kidney usually give rise to so much pain and uneasiness during their formation that they are brought under the notice of the physician at an early period: pain referred to the region of the kidney, more or less constant in character and aggravated by exertion, with occasional hæmaturia, general impairment of health, &c., causing the patient to seek relief before they have reached a large size. It is most unusual for them to attain to such a large size and number, causing so great an amount of destruction of renal subtance as in this case, before producing symptoms of local disease.

Mary Anne R——, aged thirty-two, was admitted on Nov. 8th, 1884. She had been married twelve years and had had four healthy children, who were all living. Her mother was living and strong, but her father died in an asylum. The patient says she has been ailing for a year, gradually losing appetite and wasting, but has never had any pain till the last week. Three weeks ago she had an attack of vomiting, and about ten days ago noticed a swelling in her left side. On admission she was found to be very emaciated, weighing 6 st. 3 lb., and weak. Her skin had a pale and slightly earthy tint, it was also dry and harsh with long downy hairs on the back. Her tongue was dry and slightly furred, her appetite very bad, she did not vomit, and the bowels were open. At times she had attacks of pain in the abdomen. Upon examination a large rounded tumour was noticed in the left lumbar region, extending downwards and inwards, and measuring about 7 in. in length by 4 in. in breadth. It had a smooth soft feel, but no fluctuation could be felt. Something could be traced running over it from above downwards, which moved about and appeared to be the descending colon, but it did not alter the dulness of the tumour. The lower border of the swelling reached 1½ in. above the left anterior superior iliac spine, and extended across to the middle line. Above, the dulness extended to the seventh rib. In the right lumbar region there was another tumour similarly placed, measuring 5 in. in length and 3 in. in width, and extending obliquely downwards and inwards; but instead of the soft smooth feel of the other, it had a very irregular form and feel of stony hardness. It had a sharply rounded border, under which the fingers could be inserted. An irregular upper edge could be felt, and the tumour seemed to be entirely distinct from the liver. They were both fixed and not at all tender or painful, and over both absolute dulness was obtained. When the back was examined, on both sides there was absolute dulness reaching from the spine to the tumours in front. Vaginal examination showed that the uterus was normal and the pelvis free from disease. The chest was in a fairly healthy condition, but the pulse was very weak and small, and the cardiac sounds rather indistinct. The urine had a specific gravity of 1025; it was pale, but turbid, with a stringy deposit. It contained about one-eighth of pus, and, after boiling, about five-twelfths of albumen; but nothing but pus and epithelium cells could be detected microscopically.

During the first week that the patient was in the hospital the left tumour increased rapidly in size, and became distinctly fluctuating, and the question of aspiration was being discussed when severe paroxysms of pain set in, and lasted several hours, the patient being in agony until relieved by opiates. After the pain had become easier, it was found that the tumour on the left side was much smaller than when the patient was admitted, and it continued so to lessen that no prominence could be seen. At the same time the pus in the urine increased to one-half, and for some days large quantities were passed in this way. The patient was evidently getting weaker, and died from syncope on Nov. 23rd.

Autopsy.—When the abdomen was opened nothing abnormal was to be seen until the intestines were pushed back, when in the place of each kidney a large swelling was noticed. On closer examination, the one on the left side was found to be 8 in. long by 4 in. wide and 3 in. deep, and the renal vessels and ureter could be traced entering it, and the descending colon passing over it. When opened, it was found to be a thin-walled sac full of pus, the walls nowhere exceeding ⅛ in. in thickness, and for the most part no thicker than the skin. After the pus had been removed the organ weighed nearly 10 oz. Its interior was divided by septa into four conical sacs, all communicating with each other at their apices and roughly representing the pyramids. In two of these sacs there were calculi from ½ in. to ¾ in. in diameter, whilst in the pelvis and commencement of the ureter there was another calculus, shaped like a very elongated cone, which completely blocked the lumen of the ureter when pushed down. No trace of ordinary kidney substance could be found. The right kidney was also much enlarged, measuring 7 in. in length by 4½ in. in breadth, by 3 in. in depth. Its hard irregular feel at once indicated that it was full of large calculi. It weighed, with the calculi, 18½ oz. When opened there was found to be a small, thin capsule of healthy kidney substance surrounding five large calculi; these were rounded and irregular with prominent bosses, and were so closely embedded in the renal substance that this had to be torn in some places to show them; the largest measured 5 in. in length and 2½ in. in its greatest diameter, and had three outstanding processes. The next was 3¼ in. long and 2½ in. broad, and the other three were almost as large. In the pelvis another was found 2 in. long and ½ in. in diameter, being horn-shaped, and filling up the pelvis, and beginning of the ureter. The calculi on chemical examination were found to consist of carbonate of lime, mixed with a little fibrinous material; the lymphatic glands on both sides were much enlarged; the other organs both in the abdomen and thorax were healthy.

Remarks by Dr. DINGLEY.—The chief interest of this case lies in the fact that the physical signs and clinical characteristics were elucidated by the autopsy. The soft fluctuating tumour on the left side with pus in the urine pointed strongly to either pyonephrosis or perinephritic abscess, whilst the paroxysms of pain followed by diminution in the size of the tumour, accompanied by a corresponding increase in the amount of pus in the urine, pointed almost conclusively to the presence of a calculus. The diagnosis of the condition in the other kidney was not so clear, as the calculi were so embedded in the kidney substance that no grating or movement could be obtained; the position of the tumour, its fixity, and the presence of calculi in the other kidney were the most important indications. The most remarkable feature of the case is that with such an advanced morbid condition and calculi in both pelves the patient should, with the exception of the attack noted above, have escaped without any pain, and should only have had her attention aroused by noticing the tumour. It is also interesting as showing with what a small amount of secreting renal substance life can be maintained. Of course, in such an advanced state, active treatment was out of the question; but had the case come under observation earlier, it would be worthy of consideration as to whether, by a lumbar incision and free drainage, the patient's life might not have been prolonged.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Cancer in a Cirrhotic Liver and Adrenals, with Pigmentation of Skin and Viscera.—Atrophy of Adrenals with Addison's Disease.—Infiltrating Growth in Liver and Adrenals of an Infant.—Addison's Disease.—Myoneuroma of Pituitary Body.—Tumour of Pituitary Body.—Hypertrophic Cirrhosis and Congenital Disease of Kidneys.

AN ordinary meeting of this Society was held on Tuesday last, Dr. J. S. Bristowe, F.R.S., President, in the chair. Perhaps the chief interest of the evening centred in the specimens of tumours of the pituitary body; the long discussion which many anticipated on the subject of the relation of Addison's disease to the adrenals did not take place.

Dr. CARRINGTON showed specimens from a patient aged fifty-four, who for two months before admission into Guy's Hospital had been suffering from epigastric pain and growing weakness, which had become so great that he could hardly walk across the road. The skin was everywhere of a walnut-brown, except in the axilla; the mucous membranes were not stained. In the epigastrium was a tumour evidently connected with the liver. He gradually became more and more feeble, and died three weeks after admission. At the necropsy the body was well nourished, the lungs were of a deep-black colour and œdematous; the blood was fluid, and there were ecchymoses beneath the pericardium. The site of each adrenal body was occupied by a cyst the size of a large orange containing soft brown grumous blood-clot. The surrounding tissues were not infiltrated. The liver weighed sixty-two ounces, and was extremely cirrhotic; its colour, internally and externally, was black. Scattered thickly through the organ were nodules, looking like altered blood-clot; several were as large as a pullet's egg. The spleen weighed thirteen ounces, and was very black externally and internally. The case was worthy of note on account of the obscurity of its pathology; though the naked-eye appearances were of cancer of the adrenal organs, yet the microscopic examination had shown that the walls of the cysts consisted of normal suprarenal substance. The apparently secondary growths in the liver consisted of clumps of altered liver cells. The pigmentation of the skin and viscera showed either that cancer of the adrenal bodies could produce the pigmentation, or that the patient was the subject of malarial melanæmia. Microscopic examination did not, however, confirm this view.

Dr. COUPLAND exhibited a specimen of Atrophy of the Adrenals with Addison's Disease. It was obtained from the body of a man aged thirty-seven years at death. He had been under observation for four years. The symptoms began in 1879, and death took place in January, 1884. Attacks of vomiting, faintness, lassitude, and extreme debility were the symptoms of which the patient complained. The last attack of this sort appeared to have been brought on by excessive drinking—an unusual circumstance with the patient,—and ended in death. There was decided pigmentation of the skin, especially of the face, hands, axillæ, and groins, and slate-coloured patches on the lingual and buccal mucous membranes. The scrotum was pigmented, the penis less so, and the areolæ of the nipples not at all. At the autopsy some pellets of orange-coloured fat alone remained in the site of the right adrenal, and numerous nerves could be traced to this region from the semilunar ganglion. The left adrenal was thin, arophied to about one-third of the normal size, though retaining somewhat of its normal shape. There was lymphoid infiltration of the gastric mucosa, and hyperplasia of the follicular and agminate glands of the intestine and of the splenic follicles. The body was well nourished and free from any tubercular deposit. Dr. Coupland referred to five similar cases where symptoms of Addison's disease were associated with absence or atrophy of the adrenals, three being recorded in the Society's Transactions for 1882 by Drs. Goodhart, Davy, and Eastes. He then mentioned the fact of the normal atrophic changes of the adrenals and their not unfrequent congenital absence or ill development, especially in association with defective cerebral development, and pointed out how cases like the present opened up the much-debated subject of the nature of Addison's disease. Reference was made to the results of Tizzoni's experiments,[1] and to Dr. McMunn's observations on the origin of the pigments of the adrenals.[2] The suggestion that disease of these bodies might account for all the symptoms of Addison's disease could not be sustained in face of the large body of facts showing that the adrenals may be destroyed by cancer, degeneration, or atrophy without such symptoms occurring. The alternative doctrine of the dependence of the symptoms upon a lesion of the abdominal sympathetic seemed the only possible one, but in order to harmonise it with such cases as the present one it required that the atrophic changes of the capsules should be a result of some primary derangement of the nerve centre.

Dr. BARLOW showed specimens of Atrophy of the Adrenals. Though there existed a state of extreme atrophy of the adrenals, the right one still retained the cocked-hat shape. Microscopic examination proved the nature of the atrophied tissue to be of supra-renal origin. The spleen was somewhat enlarged, and its capsule thickened; the left kidney presented a small bilobed tumour, situate in and puckering the cortex; it was tough and leathery, and of rounded shape; it had the typical characters of a gumma; no reaction was obtained with iodine. The specimen came from a female patient aged forty-two, who had typical signs of Addison's disease. The duration of the illness was ten months, during which the patient was pregnant, and gave birth to a stillborn child. He considered that the possible association of Addison's disease with syphilis had not been adequately discussed. He referred to a contribution by Baerensprung on disease of the adrenals in congenital syphilis, which appeared to be of the nature of miliary gummata so far as could be made out from the drawings and descriptions.

Dr. H. SAINSBURY related an ordinary case of Addison's Disease in a man aged fifty-one. The symptoms lasted for two years, and consisted of severe pains about the back and epigastrium, with attacks of vomiting, progressive asthenia, and pale bronzing of the skin. At the autopsy the costal pleura of the left side showed patches of pigment, and both lungs were darkly pigmented. Adhesions of the right pleura and of the peritoneum were present. The adrenals were converted into stony masses, but were not adherent to the kidneys. There were minute ecchymoses of the mucous membrane of the stomach. The connective tissue around the adrenals on the right side was specially dense. The caseous change was most marked in the left adrenal body. Microscopical examination of the semilunar ganglion showed a denser fibrous tissue than usually obtained in a healthy person of about the same age. No bacilli were found in the diseased tissues.

Dr. NORMAN DALTON showed specimens of Infiltrating Growth of the Adrenals and Liver. They were taken from the body of a male child aged six weeks. The abdomen

[1] Vide THE LANCET, vol. II., 1884, p. 559.
[2] Ibid., current volume, p. 169.

was large. A syphilitic history was obtained, and snuffles were present, but no rash. The subcutaneous veins were enlarged, and the umbilicus became œdematous towards the close of life. The liver weighed thirty-seven ounces and a half; was variegated in colour, having a basis of yellowish-brown, which was mottled with hæmorrhages. A tumour, the size of a hen's egg, was found in the position of the left adrenal body, and presented a similar appearance on section to that of the liver, though the hæmorrhages were somewhat larger. Under the microscope groups of leucocytes were to be seen bounded by a stroma of fibrous tissue, which may have originated either in an interlobular hepatitis or in a thickening of capillary walls. The growth in the suprarenal showed a peculiar finely granular, almost fibrillated, substance, which stained deeply with picro-carmine, and through which leucocytes were strewn in various arrangements. This granular structure was probably a degenerated reticulum of lymphoid tissue; the medullary portion only was affected, and there did not seem to have been any infiltration. There was a history of syphilis, but in all probability the conditions were allied to those met with in cases of leukæmia. A similar case had been recorded by Mr. R. W. Parker in the thirty-first volume of the Society's Transactions; there was no syphilitic history in that case.

Mr. J. A. P. PRICE of Reading showed a living specimen of (?) Addison's Disease. Of pigmentation there was none on the face or on the dorsum of the hands, and the peculiar mottling of a dirty-brown colour was confined to the trunk, thighs, and arms. There was no pigmentation of the mucous membranes. The pigmentation had been present for three years. A swelling of the abdomen was probably due to glandular enlargement, which certainly existed in the neck. There was a slightly increasing proptosis, and this fact, together with a rapid irregular action of the heart without murmur, pointed to the sympathetic nervous system as the cause of the affection.—Dr. ANGEL MONEY referred to a case of lympho-sarcoma of the left adrenal body, in which there was great development of the external genitals with growth of large hairs on the mons veneris. The child was about one year old. The liver and lungs were apparently secondarily affected. He said that Dr. Dickinson had described a similar case in an early number of the Pathological Transactions.—Dr. HALE WHITE had examined some hundreds of specimens of semilunar ganglia, and thought that Dr. Sainsbury's specimens were not abnormal.

Dr. HALE WHITE exhibited a specimen of Myoneuroma of the Pituitary Body. It was taken from a boy who died from inflammation of the meninges, apparently caused by the tumour. Microscopic examination showed that it consisted largely of striped muscle; the fibres were, as a rule, well-formed, but had here and there undergone atrophy. At one part of the section a small body about the size of a pin's head was seen. This was exactly like a sympathetic ganglion, having a fibrous sheath and several ganglionic nerve cells lying embedded in a fibrous groundwork. There was a clear space around each nerve cell, which was multipolar and nucleated. In the same part of the tumour were several bundles of white nerve fibres, some of which had undergone degeneration. Fibrous tissue containing fat bound together these nervous and muscular elements. The tumour was the size of a large hazel nut; it implicated the optic chiasma; there was extreme atrophy of the optic nerves. New growths of the pituitary body are not excessively rare, but one like this has not been previously described, the nearest approach to it being a tumour of the pineal gland containing several cysts lined by epithelium, the tissue between the cysts containing hair, sebaceous glands, fat, hyaline cartilage, smooth muscle, and nerve. Was this new growth in the pituitary body due to an included mass, or was it developed from the posterior lobe of the pituitary body, which in the lower animals remained connected with the brain more closely than in man?

Mr. BOWLBY showed specimens of a Tumour of the Pituitary Body taken from a man aged twenty-two, who had had fits ten years and headaches; he died in a semi-comatose condition. The tumour was situated at the site of the pituitary body, and consisted of a bony part the size of a large walnut, which was not closely attached to the base of the skull, and of a softer mass containing cysts filled with soft sabulous matter. The bloodvessels were very numerous, and there were masses of epithelial cells growing into the tumour. There was some true bone, and this feature, together with that of the included portion of epithelial cells, closely resembled those of the specimens shown to the Society by Mr. George Lawson. The origin of the tumour was probably to be explained on the supposition that an inclusion of more epithelial tissue than usual took place in the developmental process by which the pituitary gland made its appearance.—Mr. J. BLAND SUTTON referred to some facts in the anatomy of the nervous system of the snail, showing how the gullet passed through the nervous ganglionic ring at the cephalic extremity. He then spoke of the facts in the development of the pituitary body, which was largely composed of a nipped-off portion of the epiblast at the extreme cephalic end of what was the pharynx in the human body. A vertical section of the basi-sphenoid region of a fœtus of the seventh month showed a piece of connective tissue connecting the pituitary body with the superior constrictor muscle of the pharynx. In Dr. Hale White's case it was probable that the upper part of the pharynx had been cut off during development lower down than usual, and this would explain the presence of striped muscle fibre in the tumour, which was really a member of the class of tumours designated by the term "teratomata."

Mr. BRUCE CLARK showed a recent specimen of Primary Carcinoma of the Prostate and Base of the Bladder, taken from a man aged fifty-one, who had complained of difficulty of micturition for six weeks. A No. 19 French catheter was easily passed and the urine drawn off. The prostate could be felt per rectum much enlarged and firmly fixed. The urine was drawn off for the remainder of the patient's life; it contained blood and albumen, and had a specific gravity of 1012. Cystotomy was ultimately performed, and a piece of the growth was removed for examination. The temperature varied from time to time, and the case terminated in sudden death just after the appearance of hemiplegia and coma. At the autopsy an abscess was found at the base of the brain, and abscesses were present in the psoas muscle and lungs.

Dr. HALE WHITE showed a recent specimen of Hypertrophic Cirrhosis in a child aged nine years, who died from lobar pneumonia. The kidneys presented a shrivelled lobulated condition, probably congenital.—Dr. WICKHAM LEGG asked whether the other organs had been examined, and whether the temperature were raised. A case under his care presented the febrile chart of typhoid fever, and delirium with diarrhœa was also present. Cirrhosis was known to occur in early life in which other organs, as the heart and kidneys, were also cirrhosed. These facts tended to show that cirrhosis was not so much a local disease of the liver as a general one of the whole system.—Dr. HALE WHITE, in reply, said that he supposed the temperature was raised, as the lungs were in a state of red hepatisation.

The following card specimens were exhibited:—Dr. Coupland: Cases of Addison's Disease. Dr. Goodhart: Tumour of the Pituitary Body in a Baboon. Mr. D'Arcy Power: Knee-Joint seventeen months after Ogston's operation. Dr. Hadden: (1) Misplaced Kidney, with Short Ureter; (2) Puff-dart in Trachea; (3) Detachment of Peritoneal Coat of small Intestine, from Injury without Rupture of the Bowel. Dr. Hale White: A Calculus composed of almost pure Triple Phosphate.

HARVEIAN SOCIETY OF LONDON.

ON Thursday, the 15th ult., the annual meeting and conversazione was held in the Stafford Rooms, Tichborne-street. The Council, in its report, had to deplore the death of five members of the Society, but gave a very favourable account of the Society's financial and numerical condition. Valuable work had been done during the past year, and for the remainder of the present session many interesting communications were announced. Votes of thanks were given, on the motion of Mr. W. Adams and Mr. Cripps Lawrence, to the Council; of Dr. Meadows and Dr. Silcox, to the Treasurer; and of Dr. Symes Thompson and Dr. Dawson, to the President. In his address the retiring President, Mr. G. P. Field, alluded to the recent history and to the prospects of the Society, and to the sad losses it had experienced during the year; and acknowledged with satisfaction the result of the general appeal made in favour of the widow and orphans of one of the Society's most distinguished members, the lamented Dr. Mahomed. The subject selected for the address was the progress of medical

science during the period which had elapsed since the foundation of the Society in 1831. The vast improvements and the marvellous discoveries belonging to that period were reviewed in decades. The germ theory of disease, now in the ascendant, was chosen as an illustration of the remarkable oscillations to which medical opinion is liable. Medical literature, medical legislation, and medical ethics were included in the survey of recent advances. Honours were slow to reward the labours of the profession; they had not exceeded an average of a title and a half each year. But while the healing art was not represented in the House of Lords, "Poetry and Porter had equally secured Peerages." The address concluded with remarks on the desirability and practicability of founding a teaching university in London. The thanks of the meeting for Mr. Field's valuable address having been carried by acclamation, the President announced that the officers proposed by the Council had been duly elected. Dr. T. Morton, the new President, then took the chair, and declared the conversazione open.

The following names are those of the officers elected for the ensuing year. An asterisk is prefixed to the names of those gentlemen who did not hold the same office during the preceding year:—President: Dr. T. Morton. Vice-Presidents: Dr. Ferrier, *Mr. Malcolm Morris, Dr. J. H. Staples, *Mr. Charles Vasey. Treasurer: Dr. T. Buzzard. Hon. Secretaries: Mr. J. E. Lane, Dr. Wm. Ewart. Council: Mr. Bryant, Dr. Cavafy, Mr. H. E. Juler, Dr. Symes Thompson, Dr. Dunbar Walker, *Mr. G. P. Field, *Mr. F. Otley Lovell, *Dr. Kirkpatrick Picard, *Mr. W. H. Platt, *Mr. H. Power, *Dr. Gilbart Smith, *Dr. John Williams.

The conversazione was enlivened by musical performances and the display of numerous objects of scientific, artistic, and historical interest.

MEDICAL OFFICERS OF HEALTH SOCIETY.

Small-pox Hospitals, their Influence on Surrounding Populations.

AT a meeting of this Society, held on Jan. 16th, at Adam-street, Adelphi, Dr. T. O. Dudfield, President, in the chair,

Drs. E. T. WILSON, GWYNN, and TRIPE each read a paper on the Influence of Small-pox Hospitals on Surrounding Populations. The following are abstracts of the papers:—

Dr. WILSON said that the occasional spread of small-pox *in the imm*ediate neighbourhood of small-pox hospitals in the metropolis seems to be an acknowledged fact; at the same time it is clear, from Dr. Thorne Thorne's exhaustive *inquiry*, that no such extension of the disease has ever been known to take place in even the largest provincial towns. How is a difference so remarkable to be explained? Are the *ordinary* channels of small-pox spread, acting under the altered conditions of a dense population, sufficient to account for the facts, or are we driven to seek for some altogether *new factor*, peculiar, it may be, to the metropolitan area? The answer is important, as on it would seem to hang the very existence of isolation hospitals for small-pox in London even in their present modified form. Those who hold that no new element has been introduced would point to the exceptional facilities which have existed up to a very recent *period*, perhaps exist even now, for the extension of small-pox around the isolation hospitals: defects of site and of construction: ingoings and outgoings with but slight precautions: abuse of the ambulance system; convergence of friends upon the hospital, and of patients who often walk through the streets; surroundings generally of the poorest; cases treated at home or concealed;—these and other causes too numerous to mention are, it is maintained, sufficient to account for any undue spread of the disease in the neighbourhood of small-pox hospitals. There are others, however, notably Mr. Power, Dr. Tripe, and Dr. Gwynn—who have felt themselves compelled to the conclusion that, whatever may be the case elsewhere, in London the infectious matter from small-pox hospitals is carried through the air for distances of a mile or a mile and a half. The evidence for this remarkable theory, first propounded by Mr. Power in 1881, rests on statistics chiefly, and on facts which certainly admit of more than one interpretation. Much stress is laid, for instance, on a graduated intensity in the number of houses invaded round small-pox hospitals, although in some cases the houses and population have been so varied in character as to render any comparison between districts useless, and in others the intensity has resulted from a convergence of disease commencing at a distance, and not from any divergence springing from the hospital as a centre. Again, whilst Mr. Power holds that the spread takes place at the commencement of an epidemic only, when acute cases begin to accumulate in a hospital and atmospheric conditions are favourable (these being a still, foggy air, deficient in ozone), others contend that the spread is noticed towards the close of an epidemic—under atmospheric conditions very varying, sometimes in the direction of the wind, sometimes in its teeth,—and apparently in entire independence of the number of acute cases at the time in the hospital. Such contradictions cannot but give rise to the suspicion that neither the atmosphere nor the numbers in hospital are concerned in the spread round these buildings, especially when it is found that the waves of intensity during an epidemic period are synchronous to a very remarkable extent around the various small-pox hospitals and in the metropolis as a whole; that, moreover, whole streets and buildings with susceptible individuals, in the closest vicinity to small-pox hospitals, often enjoy an immunity from the disease quite unaccountable on any theory of distal aerial spread of the infection. The distribution of cases also in both time and space, especially in Mr. Power's investigation, points to some causes acting continuously within the district rather than to any emanation from the hospital itself. On these grounds, and in view of the known causes of small-pox spread, giving rise to thirty or even fifty cases from a single one, it is contended that there is no need of a hypothetical aerial spread of infection to account for cases whose origin cannot be traced; and that a small-pox hospital *per se*, and independently of its operations and intercourse with the neighbourhood, is not necessarily a danger to the surrounding population.

Dr. EDMUND GWYNN read a paper dealing with the question, Could a small-pox hospital limited to thirty or forty beds be maintained in a crowded neighbourhood without danger to the surrounding inhabitants? Abundant proof had accumulated that in former epidemics small-pox had increased greatly in the neighbourhood of large hospitals. In Hampstead all the houses lying between the hospital and Haverstock-hill in the epidemic of 1872 were attacked, and in the epidemic of 1877 there was a great concentration of disease in houses adjoining the hospital. But in the epidemic of 1881, when the hospital was closed, the houses and streets in the vicinity were almost entirely free from small-pox. The Hampstead Hospital was again opened for small-pox cases on April 6th, 1884, the largest number of admissions in any week being 44, and in some weeks the numbers in hospital fell to 7 and 5. Three or four weeks after the opening of the hospital a large increase in the number of cases in Hampstead occurred; the houses near the hospital were not the first attacked, the chief outbreak being in the district of Belsize. These latter houses were distant from the hospital from one quarter to half a mile, and during the period they would receive their infection the wind blew steadily from the direction of the hospital on to them. After the first week in June the number of houses invaded within a quarter-mile circle from the hospital continued to rise steadily in proportion to the other houses in the parish, until at the end of eight months out of 310 houses in the special area 62 had been attacked, against 134 out of a total of 6870 houses contained in all the parish. In the epidemic of 1881 the special area, containing 267 houses, contributed only four, against 36 in all the parish. Thus with the hospital open the incidence on houses in the special area had increased to 20·9 from 1·5 with the hospital closed. A similar area taken around the workhouse showed only an increase of 1·5 over ·57. The death-rate from small-pox per 1000 deaths had risen from 2·1 in 1881 to 15·3 in the present case. The author asked, if the explanations offered to account for the spread of disease in the neighbourhood of the hospital by concealed cases, by overcrowding, by the natural march of the epidemic from east to west or south to north, are to be accepted as satisfactory when the hospital was open, why did the disease almost absent itself from this particular quarter during a severe epidemic when the hospital was closed? The entrance to the hospital was formerly on the west side, yet disease in former epidemics concentrated itself on the east side, where ambulances only come to remove cases by reason of a barrier erected in Fleet-road. In the present case the barrier had been removed and the entrance was now in Fleet-road, yet the disease first appeared on the west side. There appeared to be little spread of disease on the line of sewer above the

hospital. The author believed the danger from the hospital to arise from its action being continuous, whereas local outbreaks in other quarters could be effectually dealt with by disinfection and removal of cases.

Dr. TRIPE began his paper by stating that if it be admitted that the infectious matter of small-pox can infect at a distance, say, of twenty yards—and this is allowed by most authorities,- he could not understand why, under favourable circumstances, it could not infect at a greater distance, especially as no one assumed that the poison could be destroyed in a few minutes. He then referred to the great difficulty in ascertaining the precise source of infection in most cases, and therefore of assigning aerial infection as a means by which the disease is spread. This is especially the case as regards the Homerton hospital, where the visitors and tradespeople going to the small-pox and fever hospitals enter and come out by the same gate, and where the wards are much too near the street. After describing the position of the hospital as regards the streets and open country, he brought forward statistics to show how that in all the epidemics since that of 1870-71 the inhabitants of the streets near the hospital had suffered far more than those at a distance from it; that the high rate diminished as the distance from the hospital increased, and that although other outbreaks nearly as severe had from time to time occurred in other parts of the district, yet they had not occurred in every epidemic, as was the case with the streets near the hospital. As regards the proposition that the disease is spread by aerial infection, Dr. Tripe stated that in March, 1884, an outbreak of sixty-seven cases in six days occurred in a part of the district (to the south-west of the hospital), where there had been but two cases a fortnight before, and where it was in his opinion impossible that the disease could have been caused by the so-called ordinary modes of infection. In this instance the wind veered three times all round the compass from south-west, and blew on each occasion for some time east-north-east or north-east from the hospital. There was almost a calm on two occasions, and the air was unusually moist for March. Dr. Tripe again expressed his belief, which he had stated before the Royal Commission on Hospitals for Infectious Diseases, that the infection may be carried over a high building, and he gave what he considered reasonable proof of this assumption.

In the discussion which followed the reading of the three papers, the President, Drs. Gibbon, Iliff, Pringle, and others took part.

ACADEMY OF MEDICINE IN IRELAND.

A MEETING of the Medical Section was held on Dec. 19th, the President, Dr. Cruise, in the chair.

Dr. WALTER SMITH read a paper on the Nature and Treatment of Lupus. He found the frequency of occurrence of lupus in Ireland (Dublin) to be about 1 in 200 cases of skin disease. In England and Scotland the proportion is about one in fifty. He drew attention to the differential diagnosis of lupus, but he dealt chiefly with the arguments in favour of the doctrine that lupus is a branch of the tuberculous stock and is produced by an organised pathogenic virus. These arguments are derived from three sources—viz.: (1) clinical, (2) histological, (3) experimental. Viewed clinically, numerous skilled observers in England, France, and Germany recognise the points of contact between scrofula and lupus, and note the frequent coincidence of cheesy affections of the glands and joints with lupus. In 1883 among thirty-eight patients under M. Besnier's treatment for lupus in St. Louis, eight presented well-marked physical signs of phthisis. Histologically, the close resemblance between a caseating miliary tubercle and a lupus nodule had been often pointed out, and quite recently Dr. R. Koch had furnished decisive proof. He examined seven cases of lupus: in four, excised bits of skin; in three, scrapings of the lupus tissue. He found tubercle bacilli in all the four excised bits, but never more than a single bacillus in a giant cell. Experimentally, both culture and inoculation experiments had yielded positive results. As to the treatment, it was pointed out that if the tuberculous doctrine of lupus be accepted, it strengthens the position of those who advocate constitutional treatment, and especially anti-strumous remedies. The different plans for dealing locally with the lupus neoplasm were referred to, particularly the methods of linear scarification and of erasion.—Dr. HENRY KENNEDY said he had in his practice combined constitutional with local treatment, and of thermal applications he had used plain hot water, as hot as the patient could bear. In one case he established an issue in the patient's arm, which had the effect of keeping her face well for six years. All that time she wore the issue. Cod-liver oil was one of the best constitutional remedies. It was remarkable, as showing the constitutional history of the cases, that the moment the health became impaired the disease reproduced itself. He had used blistering with good effect.—Dr. ARTHUR BENSON alluded to some experiments made on rabbits by introducing pieces of living granulations, taken from the conjunctiva of a child suffering from lupus, into the eyes of the animals. One rabbit died after a week from hæmorrhage into the stomach. The eye was examined and found healthy. In the eye of the other rabbit there soon appeared patches of tissue of a yellowish colour with a pinkish appearance, very similar to what is recognised as tuberculosis of the cornea. After three weeks this animal succumbed to chloroform, and sections made from the enucleated eye by Dr. Abraham exhibited tuberculosis of the cornea and iris. Almost all the patients he had seen with lupus of the conjunctiva showed a marked tubercular tendency, but without lupus appearing elsewhere in the body.—Dr. DOYLE said when he was a student lupus seemed to be a prevalent disease; but he had reason to think that in a number of the cases eczema had been mistaken for lupus.—Dr. CORLEY was not so sure of the bacillary theory in this disease as some recent writers on the subject appeared to be. Having had large experience in the treatment of lupus, he had tried several remedies—red iodide of mercury amongst others; but latterly he had chiefly employed the method of scraping with Volkmann's spoon, which he thought gave the best results. Still some of these cases returned after two or three months, when he had to repeat the scraping, the disease having reappeared. Undoubtedly, constitutional treatment, especially by cod-liver oil, was of great value in some cases.—Dr. FINNEY said his treatment was chiefly scooping combined with linear incision. The cases in which he adopted scooping were those where the lupus was in the tuberculated form, and not where it had formed large thick crusts. Thus, where the tubercle was disseminated with a certain amount of skin between the patches, a good cicatrix might be anticipated. If a portion of skin apparently healthy, but not really so, was left without being touched with the nitrate of mercury, lupus nodules developed again. In many cases the return of disease was due to the inefficiency, rather than the inutility, of the treatment. The intense pain caused by exposure to cold wind in some of his cases was relieved by the scraping process and linear incision and burning out every spot with nitrate of mercury.—Dr. ROBERT M'DONNELL related the particulars of a case in which various remedies, including arsenic, had been tried, without having given permanent relief, until eventually the patient was cured by the free use of cod-liver oil internally; but she died some years afterwards from phthisis, showing the tubercular character of the disease in this case. Whilst a student in Paris, under Cazenave, he had paid a good deal of attention to the disease. Cazenave observed a case of lupus of the face, which became attacked by erysipelas, and, although fearing this complication would make the disease a great deal worse, to his surprise, when it passed away the patient got rapidly well. Effects of this kind suggested the use of counter-irritants to imitate erysipelas; and Cazenave, after using a number of irritants for the purpose, gave preference to red iodide of mercury ointment; but, beyond comparison, the greatest improvement of the time in the treatment of the malady was the scraping with the spoon and then rubbing the raw surface with a rough sponge. He had used this method a great many times, and had never been disappointed. There was a form of lupus in which, if arsenic was given at all, it should be in such doses as would produce poisonous symptoms, to act as mercury does where it was intended to produce marked salivation. It produced rapid improvement, but he could not say that a permanent cure was always effected.—Dr. WALTER SMITH, in reply, said the diagnosis of superficial lupus of the ear from eczema was shown by a loss of tissue when the crust was removed. So far as he knew, the bacillus was only found in tuberculous and scrofulous affections, and not in large ulcers, and therefore it could not be introduced from without. Lupus on a single surface like the cheek seldom ulcerated deeply; but when it attacked the nose it acted on both surfaces, and

thus caused great destruction of tissue. He could hardly lay down a specific rule as to which cases were most suitable for scraping. Spots of lupus too small to be scraped he treated by drilling with a pointed piece of wood tipped with nitrate of mercury.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

AT the meeting held on January 9th, Dr. Bell, President, in the chair, after the exhibition of several pathological specimens,—

Dr. JAMES BRAITHWAITE related a case of Fibroid Tumour (Sessile) in the Anterior Wall of the Uterus. This was removed from the peritoneal surface of the uterus by enucleation, and a large abscess was opened into the capsule of the tumour. The abdominal wound was closed, but free drainage was provided for by the capsule being stitched to the lower angle of the wound. The patient was in a very bad condition at the time, having been tapped for ascites repeatedly; and she died within twelve hours from cardiac thrombosis.—Professor JESSOP remarked that his experience of the removal of uterine myoma by abdominal section was limited to three cases. In 1865 he performed hysterectomy by the extra-peritoneal method in a case of very large multiple myoma, and the patient died after the removal of the clamp on the sixth day. A few years later he operated in a similar case by the intra-peritoneal method, and the patient died in the course of a few hours. A few weeks ago he operated by enucleation in a case in which the tumour weighed between 4 and 5 lb. He found some difficulty in stripping the tumour of its cyst; but there was not much haemorrhage. In dealing with the cyst he inverted its edges so as to bring the serous surfaces in contact to the extent of about the upper five-sixths, and stitched the margins at the lower end to the abdominal wall for drainage. The patient is now convalescent, and Mr. Jessop hopes to bring her for inspection on a future occasion.—Mr. C. G. WHEELHOUSE mentioned two cases of abscesses in the uterine walls, one of which opened primarily into the bladder, the other directly into the uterine cavity, and both of which, the former by mechanical dilatation of the urethra and the latter by dilatation of the uterine cervix, were reached, cleansed, drained, and cured.

Dr. HELLIER read some notes of a case of Hysterical Ischuria in the case of a young lady aged fifteen, in whom for a period of nearly seven weeks there was marked scantiness of urine, interspersed with periods of complete suppression. On two occasions there was no secretion for forty-eight hours, and once, it was asserted, no urine was passed for five days. The case was associated with severe attacks of gastralgia, with obstinate constipation and menstrual irregularity, but there was little vomiting and no uræmic symptoms. After considering the possibility of fraud, Dr. Hellier discussed the reasons which led him to employ the somewhat unsatisfactory term "hysterical," criticised some of the common definitions of the word, but pointed out that it must be retained for the present because of its very practical meaning in (1) diagnosis, (2) prognosis, (3) treatment, with special reference to the employment of moral means of cure.

Mr. MAYO ROBSON showed a patient who had sustained an extensive laceration of the arm, leaving a large gap seven inches long by three wide in front of and above and below the right elbow-joint, exposing the brachial artery. After a sharp attack of secondary hæmorrhage on the fifth day from ulceration into the brachial artery, which necessitated its ligation, healthy granulations covered the wound, and on the sixteenth day after the accident a large flap of skin with its base below was reflected from the thorax and placed directly on the granulating surface, being left attached by a pedicle two and a half inches wide, which was separated on the twelfth day. The flap had nearly all lived, and the patient had now a sound right arm with every movement perfect. The points of interest in the case were: (1) The transplanting of the flap directly on to granulations, and not on a refreshed surface; (2) the question as to whether or not the brachial should have been ligatured at first, thus saving the patient the danger of death from sudden rupture. Bearing on this point, Mr. Robson had seen a wound heal without hæmorrhage, in which the carotid artery was not only exposed, but even notched.—Dr. BARRS pointed out the little tendency blood-vessels have to participate in pathological changes going on in their vicinity, so long as the blood stream through them is uninterrupted.—Professor JESSOP related several cases where he had successfully transplanted flaps on to granulating surfaces.—Mr. Wheelhouse and Mr. Ward spoke, and Mr. Robson replied.

Mr. W. H. BROWN related a case where two months after Amputation of a Stiff Index-finger following Whitlow the stump became so tender that the patient begged to have it removed, which was done. The removed portion was examined by Dr. Griffith, who reported that there were two small fibrous nodules situated in depressions at the end of the bone. These consisted of nerve-fibres embedded in fibrous tissue.—Professor JESSOP related a case in many respects like the above in which amputation of the finger failed to relieve, but after years of suffering the neuralgia spontaneously disappeared.

Dr. CHURTON read notes of a case of Syphilis very early affecting the nervous system, and showed the patient, a man aged twenty-four years, strong but of dissolute habits, who had had a chancre four months ago. Two months after this he had sensory disorders in his right foot, spreading to the whole limb, and shortly after to the left foot and limb; he staggered in walking. A month later the hands became affected; he could not cut his food or pick up a match; he could not distinguish any object with accuracy by the sense of touch. When admitted into the Leeds Infirmary he seemed dazed and gave varying replies; he could not walk at all nor stand alone, even with his eyes open and anxiously watching his legs. The plantar and patellar reflexes were absent; simple muscular power somewhat feeble, no special wasting of muscles. Under treatment by mercurial inunction, rest, and abstinence from alcohol, the patient had in three weeks so much improved that only slight symptoms of ataxy remained.

Mr. MAYO ROBSON showed a girl, aged sixteen, from whom he had removed, on Dec. 10th, the sac of a Spina Bifida the size of a fœtal head, on account of severe brain symptoms, apparently due to inflammation of the sac, great increase of fluid, and pressure on the nervous centres. The patient was in good health, and presented only a cicatrix over the site of the tumour. He drew attention to: (1) Simple tension, raising temperature; (2) suppuration set up by tension, and not necessarily by septicity; (3) the new departure in the treatment of such cases; and (4) the excellent result of the operation, which undoubtedly saved the life of the patient.—Dr. Eddison, Mr. M'Gill, and Professor Jessop joined in the discussion.

Reviews and Notices of Books.

Scientific Papers and Addresses. By GEORGE ROLLESTON, M.D., F.R.S., &c. Arranged and Edited by WILLIAM TURNER, F.R.S.; with a Biographical Sketch by EDWARD B. TYLOR. Two Volumes. Oxford: Clarendon Press. 1884.

WE have experienced great pleasure in reading these memorials of a very active, vigorous, and independent worker and thinker. The subjects of which they treat are multifarious, and all as he treats them are rendered interesting. Whether we open the volume at the chapters devoted to the series of prehistoric crania which he with Canon Greenwell took such pains to unearth and describe, at that in which he discusses the origin of the domestic pig, at the place where he inquires into the cause of the rot in sheep, where he so nearly gave a correct solution in naming the black slug instead of the Limnæus since shown by Lewis to be the real delinquent, or at some other of the numerous essays contained in these volumes, we cannot fail to be struck at the amazing extent of Dr. Rolleston's knowledge, the facility with which he adduces and arranges facts, and the caution with which he draws inferences from them. Rolleston was indeed a brilliant man. His memory was singularly tenacious and his powers of work extraordinary. In fact, his too early death may be in great part attributable

the increasing demands he made upon his mental and to bodily powers. *Apropos* of this, we once heard him tell the following anecdote. He had been, as was his custom, hard at work in the museum, and was returning home, when a stranger accosted him with, "Ah, Professor Rolleston, I am glad to have met you, for I find I have half an hour to spare, and I should be so much obliged to you if you would show me over the mus——" "You have found a spare half hour," interrupted Rolleston; "for God's sake give it to me; I have been looking for it all day."

The work is introduced by a charming biographical sketch by his friend Edward B. Tylor, the present Reader in Anthropology, in which such details of his early life as are known, and many extracts from his letters, are given. Rolleston was born in 1829, and whilst very young was devoted to natural history; at the age of six setting traps in the grounds of his father, and dissecting mice and weasels. Not less significant of his future, Mr. Tylor observes, was his setting up heaps of stones to record the death of a favourite animal, or other event. A boy who at eight years old piled up in the plantation a memorial cairn to commemorate his sister's recovery from scarlatina was well started on the line for an explorer of ancient burial-grounds. Early imbued with a sound knowledge of Latin and Greek by his father, at the age of twenty-one he took a first-class in classics, and next year was elected a Fellow of Pembroke. The Fellowship was a medical one, and naturally determined him to take to medicine as a profession. He entered at St. Bartholomew's Hospital, and worked there long and hard. The outbreak of the Russian war led to his departure for Smyrna, and to his doing duty in the general hospital. At the close of that war he returned to Oxford, and was soon appointed to the Linacre Professorship of Anatomy and Physiology (1860). In 1861 he married Grace, daughter of Dr. John Davy and niece of Sir Humphry Davy, by whom he had seven children. He died from renal disease in 1881. Though never lecturing to large classes, he worked at each lecture with untiring assiduity. He made many warm friends amongst his pupils, and he was proud and pleased to say that they never forgot their old master; from them he was constantly receiving specimens, which, whilst they filled the shelves of the museum, told him that the lessons he had taught were bearing fruit, and that he was affectionately remembered by men who were separated from him by many years of time and by half the circumference of the earth. Professor Turner has collected no less than seventy-nine memoirs and addresses, which have been published, to which are added three hitherto unpublished notes. There is not one of these which is not interesting, and which, if it have been already read, will not bear a second perusal; not one that is not illustrated by his varied learning and accurate powers of observation. A large number of them are anthropological, deal with the contents of barrows, and give an account of researches and excavations in various parts of the country; others deal with zoological subjects; the majority are, however, occupied with points of anatomy and physiology, on which he was constantly engaged. He leaves a brilliant name to his children. We can wish them nothing better than that they should emulate his earnest and useful life.

London and Provincial Water-supplies, with the latest Statistics of Metropolitan and Provincial Waterworks. By ARTHUR SILVERTHORNE, Assoc. M. Inst. C.E., Consulting Engineer. London: Crosby Lockwood and Co. 1884.

THIS is a carefully compiled and most valuable statistical account of the water-supply of London and about eighty of the other principal towns of Great Britain and Ireland. The book will be a real boon to all practical sanitarians. It consists partly of tables showing the sources of supply, the quantity supplied, the population, the rateable value, the expenditure and revenue, the scale of charges, and some other details for each important town, and partly of a critical and historical description of the metropolitan and provincial undertakings. The gigantic character of the London supply is shown by the fact that the population of Greater London is now over five millions, and is increasing at the rate of about 100,000 every year. It is estimated that if the present rate of increase is maintained, this enormous population will have doubled by the year 1919. By far the greater part of this wonderful metropolis is supplied by the eight London water companies. Mr. Silverthorne gives great and deserved praise to these companies for their general management, and expresses a strong opinion that the present supply is not only sufficient in quantity, and, with proper precautions, in quality; but is also capable of indefinite expansion to meet the wants of the constantly increasing population. He repeats the familiar arguments as to the danger and injustice of drawing our supply from distant places, and quotes with entire approval the opinion of Sir Robert Rawlinson to the effect that "to sacrifice the present source and lay out fresh capital to bring in some imaginary pure supply would be gross waste of money, and would not accomplish the object intended." From the engineering point of view this argument is unanswerable; but it must not be forgotten that the physician and the chemist have something to say on the other side.

The present supply of water to London is certainly ample, although we occasionally hear of water famines in certain districts. It amounted in 1883 to 144,592,772 gallons daily, or nearly thirty gallons per head of population. But the cost to the consumer is unfairly high, and the profit to the shareholders inordinately large. Mr. Silverthorne, who writes in the most moderate tone, points this out with great clearness. He explains the various modes by which companies can increase their profits and expresses a decided opinion that Parliament must ere long put a check upon them. The doubt we have long felt as to the wisdom of the present system is certainly not removed by the statement.

The statistics of provincial water-supply are very interesting, and occupy the greater part of the book. There is still great inequality in the supply of different towns, but of course there are much greater difficulties in some cases than in others. Hastings is still unsatisfactory, as in the time of our inquiry. The population at the last census was 42,258, and the average quantity of water supplied in twenty-four hours 700,000 gallons, or less than 17 gallons per head, derived in part from surface springs. The new works at Filsham will, it is said, add 500,000 gallons to the daily supply; but, on the other hand, it must be remembered that in the autumn the population is much greater than on the day of the census. The supply in the summer is, moreover, more scanty, and probably inferior in quality. Eastbourne, on the other hand, with a population in 1881 of 24,000, has a daily supply of 1,300,000 gallons, derived from deep chalk and greensand wells, which is equal to 54 gallons per head. Eastbourne is growing so rapidly and its summer population is so large that the supply is by no means too liberal. Brighton, with a population at the last census of 134,954, has a daily supply from chalk wells and adits of 4,500,000 gallons, equal to 33 gallons per head. Glasgow receives about 50 gallons per head each day of the pure water of Loch Katrine.

SOCIETY OF ARTS.—At the meeting of the Society of Arts on Wednesday next, the 11th inst., there will be a discussion on the recent Report of the Royal Commission on Metropolitan Sewage. It will be commenced by a paper by Capt. Douglas Galton, F.R.S. Sir Frederick Abel will be in the chair, and most of the principal authorities on sanitary questions are expected to be present.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 7, 1885.

THE distinction of the Fellowship of the Royal College of Physicians is one which is highly prized. Its value depends not merely upon the privileges it confers and the opportunities it affords for taking a share in the management and educational work of the College, but also upon the fact that it is regarded as a recognition of honest persevering labour in the sphere of medical science. It is, then, looked forward to as an object worthy of attainment by those who have resolved to devote their lives to pure medicine—a pursuit which during many years has no compensation beyond such a distinction as this. It carries with it but little social advantage, but it stamps its holder as one who has chosen a definite line in life; and it should be conferred with strict regard to such a circumstance. Nor should it be alone bestowed upon those who are entering upon a career; it is quite fitting that those who have borne the burden and heat of the day, who have earned for themselves a reputation, should also be entitled to receive almost the only honorary reward the profession can offer. Being, then, as it is the legitimate object of ambition, it is most important that the manner in which the Fellowship is conferred should be, as far as possible, above cavil and reproach. The duty that devolves upon the College in making the selection is therefore one of a momentous kind; and great care should be exercised to ensure that those who are selected are worthy to receive the distinction. It is perhaps unavoidable that now and again some undeserved hardship is apparently inflicted, and that the names of members of the College who are known to have done good and honest work are passed by. No system of election is altogether free from a blemish of this kind. But under a system which leaves the selection of candidates in the hands of a Council the risks of injustice from inadvertence and ignorance are increased. It is true that the Council is supposed to represent the whole body of Fellows, and therefore to be trusted to consider the claims of all eligible members impartially and fully. But it is impossible to expect that the Council can possess all the knowledge requisite for this task; and the unfortunate occurrence of last year, which resulted in no Fellows being elected at all, arose simply from this one reason.

It is nevertheless well known that every Fellow of the College has the right to nominate a Member whom he thinks deserving of the Fellowship, and the nominations so made are placed at the disposal of the Council, in order to aid it in its selection. Now, whether rightly or wrongly, the idea has grown up that the Council is not guided by these outside nominations at all. It is doubtless owing to this impression that the nominations received from the Fellows are absurdly few; and this very paucity suffices to lead the Council to the belief that the Fellows are willing to leave in their hands unlimited discretion. It must, then, have been a rude shock to the Council, and for our own part we do not hesitate to say a most unmerited rebuff, to have had their nomination list returned on their hands. The Fellows of the College by their act of last year, impelled doubtless by unimpeachable motives, really passed a vote of censure upon themselves; for they had neglected their duty in not making nominations, and were not satisfied with the result of the task they had thus tacitly imposed upon the Council.

The present system of election to the Fellowship, if carried out by the College and its Council as thoroughly as it should be, ought to sufficiently safeguard the College from the risk of conferring an honour where it is not deserved or of withholding one where it is merited. To deprive the Council of the prerogative of selection, and to cast the whole responsibility upon the Fellows, might give rise to a state of things much to be deplored. It would open the door to intrigue and canvassing for votes, which are the inevitable concomitants of an open election. It might split the College into factions and damage its reputation seriously, so that the Fellowship would no longer be held in esteem. No such radical change is in fact needed. All that is required is that the Fellows should feel assured that their nominations are thoroughly weighed by their representatives; that the idea that the Council are indisposed to attend to such nominations, fearing that they are often made on considerations other than those of securing the most suitable men for the distinction, should be dispelled. In a word, the Fellows as a body should trust the Council they elect that it will perform its unenviable duty of selection with the greatest circumspection; and the Council in its turn should trust the Fellows to nominate impartially those who are entitled to receive the encouragement of their professional brethren in a career that is opening to them, or the reward of their approbation for years of pure unselfish labour in their profession.

THE agitation against the lunacy laws and in favour of their reform is confessedly, in the main, factitious; but outside the area of this useless, if not actually mischievous, perturbation there is a calm and mature opinion that the law, as it stands, is unsatisfactory, and that it ought to be, and eventually must be, changed. We are anxious to make it clear, to those of our readers who do not yet recognise the position we have assumed, that while we have no sort of sympathy with the mad onslaught of agitators against the private asylum system, or with the unbridled abuse of those who keep private houses of detention for the insane, it is our mature conviction that the whole business is bad and in need of prompt and sweeping amendment. We cannot but regard the trade of keeping private asylums for the insane as incompatible with the position and obligation of members of an enlightened profession. Those who are so engaged nearly all agree with us; indeed, we could scarcely point to a single member of the profession in the way of business alluded to who has not, either publicly or privately, expressed himself in the same sense on this subject. The private asylum system is an anachronism, and those who are personally responsible for its maintenance keenly feel it to be one. If there were no central Board of Commissioners in Lunacy to cast a glamour of respectability on the trade, not a Member or Fellow of the College of Physicians would engage in

it. There must be "abolition." The only question is, how and when will it be brought about? We have no immediate hope in relation to the matter; and we must be excused for thinking that the agitation in progress, to which some among us seem to attach much importance, will not hasten the desired reform. On the contrary, we incline to think it may have the disastrous effect of postponing it.

Dr. BUCKNILL'S article in the current number of the *Nineteenth Century*, on the "Abolition of Proprietary Madhouses," falls, we fear, into the category of ill-advised proceedings in agitation for reform of the lunacy laws, and, in so far as it does so, its publication is to be regretted. It is an able composition, admirably written, cleverly argued, and we do not for a moment question the entire accuracy of the somewhat startling allegations made in it. Nevertheless, we do more than question the wisdom of making those allegations, well-founded as they may be. There is such a thing as pushing a policy of defamation too far, so that the effect shall be to turn the tide of sympathy in favour of the class abused. We do not commiserate the asylum proprietors on the position in which Dr. BUCKNILL'S paper has placed them. They are rather to be congratulated on its appearance. It is for our side of the case—the opposition—pity needs to be asked. If Dr. BUCKNILL should be anxious to know why we feel and write thus, notwithstanding that on the whole we agree with him, the answer would be simply this: the system is so bad that it is wanton as well as witless to abuse the men. Nor are all his allegations germane to the question at issue. What conceivable bearing on the private asylum system has the fact—assuming it to be a fact—that some asylum keepers have made a profit by letting out their attendants on hire? We fail to see the objection to this particular branch of the business. It is not only, as Dr. BUCKNILL describes it, "a custom of the trade"; it is a perfectly intelligible and commercially sound custom. Nor is there anything whatever more mean or less respectable in this department of the commercial enterprise than in that of letting furnished lodgings, with board, washing, and attendance included; a profit being of course made on every item of the business—house rent, the wear and tear of furniture, the food consumed, and the services of the *employés*. Why all this straining at a puny gnat, when the camel is swallowed without so much as a single grimace? Others of Dr. BUCKNILL'S specific allegations are equally open to criticism.

When reform is seriously undertaken, there will be reasonable and sufficient opportunity for the discussion of the real question at issue in all its bearings. We do not complain of the transparently silly objections of those who are interested in maintaining the existing state of matters. They urge that we have no knowledge of the subject and nothing to propose. We *have* a reasonably good acquaintance with the facts, and our proposals have been on more than one occasion placed at length and in detail before our readers. They cover the whole ground, and to them we adhere. We do not expect any great benefit from partial changes in the law. So long as mental disease is looked upon and treated as something apart from the subject of general medicine, and while special *legal* powers are demanded "for the protection of doctors," or "for the safety of society and the insane," there must be dissatisfaction, insecurity, and scandal. In truth, medical men ought to have no more to do with the legal and social disabilities of the mentally diseased than they have with the moral character, the financial position, or the educational attainments of their patients. If the profession were true to itself, it would cut the Gordian knot of all this difficulty by refusing to give or sign any document having a legal bearing or capable of being used in a court of justice, except it be to protect the insane from the legal consequences of responsibility for wrong-doing in their madness. We repeat the affirmation that no single power is needed by physicians engaged in the medical treatment of the insane which the *common* law does not give every citizen. At the present moment *lunacy* law, so far as the insane or society may be concerned, is an idle farce in Scotland: there the doors of asylums are not even locked; no sort of coercion is employed beyond that which every nurse uses in the care of a *patient*, and all goes well. Let this system be adopted throughout the country; let there be no more talk of "lunatics" in the legal sense, but only of *patients* in the medical sense of the term; let *hospitals* replace "asylums," and we shall neither need to clamour and agitate for lunacy law reform, nor will there be any longer reason or use for "certificates."

THE address of Lord REAY, in his capacity of Lord Rector of the University of St. Andrews, on University Reform in Scotland, is sure to have pleased his audience, and may be read with much interest by others. He recommends most freely the creation of new Faculties and more generous endowments of the Scottish Universities. He would have universities fulfil the double function of educating for the professions, including the teaching profession, and providing for general culture and research. He would have by all means a Faculty of Science and a great enlargement of the functions of the Faculty of Law. He would certainly retain the Faculty of Theology, so that clergymen may be trained to grasp the relation of theology to other sciences. His observations on the Medical Faculty of the Scottish Universities would have been more valuable if they had been less flattering and more critical. They were as follows: "About the Medical Faculty little need be said, as it has obtained European fame by adopting many of those improvements which I am recommending for the other Faculties. Nothing that it can possibly require should be refused to it." This is very pleasant language for Scotch professors, but it is not altogether worthy of Lord REAY, who should know that in one part of Europe at least—namely, England—there are many persons of no mean authority who think lightly of the medical work and the medical degrees of the Scottish Universities, and who have only been confirmed in their opinions by the recent action of these bodies in regard to medical legislation. Lord REAY very properly maintained that the placing of the Scottish universities on a level with universities anywhere was a matter of public, not merely local, importance. We should entirely agree to this if the Scottish universities showed a little more readiness to fall in with public proposals for testing the work they do. Their attitude to the Medical Bill of the Government has been that of bodies who believed that the empire existed for them rather than otherwise. Lord REAY explained to his audience that the first thing

for Scotch statesmen to do was to make the most of "Scotch brains," and that the great thing for the Scotch universities is to supply the empire with the professions ready-made. "We have scattered doctors and surgeons broadcast over the empire. Why should we not do the same for other professions?" Why not? That is a question which we may leave the Scotch universities to consider. They have done a great "professional" business hitherto, and it will be their own fault if they do not continue to have a large share of the work of educating the "professions" for the empire. But they must remember that the conditions are altering very much. The schoolmaster is abroad. The Education Act of 1870 has not only extended and improved popular education, but has given a great stimulus in England to secondary education. Universities, too, are multiplying—and universities that receive cheerfully any legislation in the interests of the public. The consciousness of having some slight "brains" even may overtake the community south of the Tweed, and English statesmen may be required, as Lord REAY requires Scotch statesmen, to look to the greater efficiency of universities. Not the least significant part of Lord REAY'S address was the confidence with which he predicted that London is to acquire a splendid university. We share the same faith, and we agree with Lord REAY that such an acquisition would act beneficially by way of competition with the universities of Scotland. Lord REAY would have men *qualified for professions by a university degree, and not by the State examinations, which is the system of Germany.* He may be right, but there is much to be said against this view. If university degrees become the common qualification of men for professions, they will lose that distinctive and honourable character which gives them their special value. Moreover, under such circumstances they would have to be given on low terms—we mean low examinational terms,—which would be a public misfortune. In our judgment, university degrees should be distinctions, not mere qualifications. They should imply more than mere qualification. We cannot doubt that this is Lord REAY'S meaning, for he carefully points out that the one essential element of success in a university is that the teaching should be first-rate. Would he exclude, say from the medical profession, all who cannot command university teaching and a university degree? And are the universities to concern themselves with the mere qualification of medical men, and not with their higher education? We must leave Lord REAY'S address, feeling that perhaps the newspaper report of it has not done him justice, while grateful to his lordship for raising so well questions which concern, as he says, not the Scotch universities, but the empire.

THE decision of Mr. Justice STEPHEN last February with respect to the burning of a body in irregular and revolting circumstances, asserted the legality of cremation when performed in a decent manner. The subject had never been so much considered in this country as to call for the recognition or control of law, and it therefore remained a matter of opinion. That which alone had influence over it was the law of nuisance, which operated equally in the case of burial, and more or less of every social usage. We may say, then, that the permissive stage has been reached in reference to cremation, and that to be burned or buried is at the option of every person who desires to arrange for the disposal of his body after death. The question now before us has to do simply with the advisability of the former method, and the special regulations, if any, which must guide its execution. In the course of many discussions the reasons of general public interest which may be stated on one side or the other have received due consideration. We, as medical men, are naturally desirous to concern ourselves more particularly with that aspect of the case which presents the most notable features to the medical jurist. To register a practical certainty as to the cause of death is also, we observe, justly regarded by the Cremation Society as a first essential to the success of their scheme. They propose in their latest circular, as in those formerly issued by them, to do this by means of the process now in use as the necessary preliminary to burial—namely, by certification where there has been medical attendance during life, and by the usual autopsy where there has not. They propose, in addition, to strengthen the ordinary medical certificate by a second, given on later inquiry by a practitioner who would have to decide whether the circumstances connected with the death as reported to him were sufficient to have caused it. This second assurance is really, then, a repetition of the first, for all the evidence which gives it value is derived from the same sources. The most trustworthy of these is usually of course the visiting practitioner. We admit without hesitation that for many cases these precautions would be ample. Thus, there is to our present understanding of medicine nothing in the course of ordinary acute disease, or for that matter of most diseases which are fairly common, to excite suspicion of unlawful practice. It is no less certain, on the other hand, that the natural and the artificial or criminal factors of disease may, and often do, closely agree in their effects in consequence of their acting along the same lines. Symptoms are moulded on pathology. The structural proofs of local irritation, the physiological inaction of narcotism, are the same for many of their causes. There need be no surprise therefore if now and then the most acute observer may have to trust to informants, in order to trace the history of his own diagnosis.

When we come to chronic poisoning, the uncertainty is at times great, and is very apparent in the action of such drugs as arsenic, strychnia, opium, and mercury. Cases of exhumation, on account of some suspicion as to the real nature of a fatal ailment, have commonly been of this kind, as, for example, that which resulted in the conviction of PRITCHARD. The medical attendant has in such cases, we may presume, had no doubt as to the reality of an apparent illness not due to poison, or it may be the influence of the latter has appeared to be the grateful euthanasia of exhaustion at the close of a long and painful malady. A second certificate might perhaps have been barred by some opposing trifle of detail, but no reliance should be placed on the chance of this occurring. There is no absolute security even in multiplied certificates. They follow one another in line, one may say, and the tendency to repetition is unavoidable. We do not think therefore that the advocates of cremation have materially strengthened their position by their latest circular. In the vast majority of cases in which the *bonâ-fide* course and termination of disease seem

clear to all who are interested in the patient, it is of no real consequence whether the earth or the urn is made the last resting-place, nor even whether the illness and death have been certified or not; but the question is one of law, not of fact alone. Certification is, or is understood to be, applied generally for the satisfaction of law in a few doubtful and exceptional cases. It may fail to give that satisfaction. Then the body is for a long time procurable for examination. Cremation would abolish this final evidence, without offering an equivalent guarantee that life has not been taken by design. Regarding fact as well as jurisprudence, we are unwilling to remove the legal sanction which has been accorded to the burning of the dead, even while we do not approve the practice, though we can clearly see that a feeling of insecurity must belong to it so long as cremationists admit no need for post-mortem examination except in ordinary coroners' cases.

DR. LAUDER BRUNTON'S name is so strongly associated with the scientific aspect of medicine that the Fellows of the Medical Society of London and the profession at large felt perfectly sure that his Lettsomian Lectures would deal with the subject of disorders of digestion in a scientific and able manner, and we may say at once that this anticipation has been fully justified. We have endeavoured, in giving full abstracts of these lectures, to present our readers with the most important matters upon which the lecturer touched, and we shall now make it our duty to further discriminate and arrange the material which Dr. BRUNTON has brought forward. If we were asked what two or three salient features chiefly distinguished the character of these lectures we should select the following: The consideration of the subject of diffusibility in regard to the dimensions of molecules; the importance of the part which that class of bodies known as alkaloids may play in the physiology and pathology of digestion; and the question of the action of some of the newer remedies on the intestinal and neighbouring secretions. There can be no doubt that a knowledge of molecular chemistry will prove to be the most solid and lasting foundation of physiology and pathology. The sizes of molecules, their varying constitution, the interaction of the atoms of which they are composed, and the manner in which molecules behave towards one another—these are questions which it is the aim of molecular physiology to elucidate and explain.

With regard to the diffusibility of various substances through membranes, Dr. BRUNTON has given some important information. MORITZ TRAUBE showed in experiments on diffusion through artificial membranes that a membrane of tannate of gelatine would allow nitrate of barium, with a molecular weight of 130·6, to diffuse through it, and would also allow the passage of all compounds having a smaller molecular weight; but it stopped the passage of ferrocyanide of potassium, having a molecular weight of 211·4. "Membranes may thus be regarded as atomic sieves, and if one substance will not diffuse through a membrane which will allow another to pass, we may consider that the molecules composing the substance which diffuses are smaller than those of the other." The importance of such views on the causation of certain forms of albuminuria is very great. The number of atoms in a molecule of a typical albumen is so numerous, and the modes in which these atoms may be arranged are so varied, that albumens are justly regarded as some of the most interesting chemical bodies, and a thorough knowledge of their actions and composition is very necessary; so that we welcome the prominent manner in which Dr. BRUNTON has brought forward physiological facts concerning albumens, and has given them a place in clinical medicine which men of less daring would perhaps have hesitated to assign them. But surely it is only by thus boldly asserting the practical importance of acquired physiological knowledge that we are likely to gain any large addition to a scientific understanding of the processes of disease. It is, however, with the exposition of the share which alkaloids may take in the morbid and healthy economy of the body that we are most pleased.

It is some time since Dr. BRUNTON called attention to the symptoms of nervous depression which are to be attributed to certain forms of indigestion. At that time alkaloids had not been shown to be formed in the body, but now the evidence which we have to prove the presence in the circulation of alkaloids formed in the intestine is identical with that which we have to show their presence when injected subcutaneously. BOCCI has found that from human urine an alkaloid can be extracted which has precisely the same physiological action as that powerful nerve-depressor, curare. And the alkaloid which BOCCI discovered in the urine has been stated to be identical with the alkaloid obtained by BRIEGER from the peptones formed in the process of digestion of fibrin with gastric juice, which has received the name of peptotoxin. These alkaloids may not be of identical constitution, though their action is like that of curare in paralysing the peripheral terminations of the motor nerves.

In respect of treatment, there can be no doubt that readers of Dr. BRUNTON'S remarks on this subject will gain a clearer insight into a rational mode of dealing with patients the subjects of disordered digestion. Under this heading it will perhaps be most useful to take note of the further knowledge which we appear to be acquiring on the mode of action of some of the complex bodies of the aromatic series. The influence of salicylate of soda on the secretion of bile as well as toluylendiamin, may well form a nucleus or starting-point for a most extensive series of investigations. The former of these bodies causes the bile to be secreted in very large quantities of a very fluid kind, whilst the effect of the latter is in the opposite direction. In this connexion Dr. BRUNTON observed: "We do not yet know whether a similar action on the liver is exerted by substances—we may perhaps say poisons—formed during the process of digestion in the intestine. If such substances are formed, their formation might be consequent on something wrong in the food which had been taken, or on some disturbance of secretion or absorption, or might be due to foreign organisms having been taken into the intestinal canal and having produced there abnormal decomposition."

Throughout the lecture the idea prevails that the intestinal canal is a part of the outside world; and the inevitable conclusions from such an idea—that processes allied to those which occur in the main and tributary sewers of our municipal system of drainage may occur in the *primæ* and

secundæ viæ of our inside yet outsides paces—may be drawn without conflicting with our knowledge of medicine, even if a little shocking to our sense of refinement.

THE new Conjoint Board is to be congratulated upon the recognition of the value of its examination scheme accorded to it by the University of Oxford. That university has asked permission for its members, who have passed the earlier stages of study, to be eligible for the final examination without passing through the first and second. On their part the Colleges have resolved to admit to the same privileges any member of an English university. We believe that Edinburgh has made a similar application, so that the next very important matter which the *English* Conjoint Board will have to decide will be whether it should afford equal facilities to the students of the Scotch and Irish universities as it does to the English. At a time when the proportion of Englishmen studying medicine in Scotland is steadily increasing, any proposal to still further encourage this exodus by bestowing upon the students of Scotch universities privileges of the same kind as are afforded to those who prefer to remain in England might lead to opposition. Yet, if the Conjoint Board is satisfied that the anatomical and physiological examinations passed by the graduates of Scotch and Irish universities are of the same stamp as its own, it would be unjust to decline any extension of such privilege to the whole of Great Britain and Ireland. Indeed, the London Colleges must feel gratified that there does exist so widespread a desire to obtain their diplomas, and they will act wisely in not placing any uncalled-for obstacles in the way of candidates. The question is one which, however, demands most careful consideration. Meanwhile, an even more important step is proposed to be taken by the University of Oxford. It is this: it will regard the passing of the final examination of the Conjoint Board as equivalent to the final examination for a degree in medicine; but before conferring the degree it will demand of its graduate evidence of higher study, in, we presume, the form of a thesis upon some subject in scientific medicine. We trust that this scheme will speedily be sanctioned by the university. For although it may be said that Oxford thereby gives up its legitimate sphere of medical examination, it only does so to a certain extent. Its students now spend their final years at the London hospital, for Oxford has not the means of providing a clinical education. To the Oxford student it will have the advantage of diminishing the number of his examinations; whilst the university will retain an influence upon higher medical learning which will do more for medicine than any attempt to resuscitate what has been termed the "lost medical school," in a city which does not possess that very necessary part of a medical school—a wide field for clinical instruction. We shall follow with interest the practical working of these proposals.

A NEW mission hospital is being erected at Hang-Chow, the cost being borne chiefly by the William Charles Jones Fund, administered by the Church Missionary Society. Many English and Americans in China have also contributed, and even the mandarins of Hang-Chow. Dr. Duncan Main is the medical missionary in charge.

Annotations.

"Ne quid nimis."

INDIAN MEDICAL SERVICE.

WE learn from our contemporary, the *Broad Arrow*, that the Indian Government has come to an important decision with regard to the travelling expenses of officers wishing to enter the Staff Corps. "Hitherto officers leaving British regiments to join probationary appointments in native regiments have been obliged to defray their own travelling expenses, on the grounds that they are proceeding to an appointment for their own advantage, and also benefiting pecuniarily by the arrangement. In future these officers are to be exempted from the operation of this rule, and to be allowed passages at the public expense, under the circumstances mentioned." The new regulation appears to us to have an important bearing upon one of the undoubted grievances of the medical officers. We have repeatedly called attention to the injustice done them in being required "to pay their way to all appointments in which they draw higher pay." The expense thus incurred is in many instances greater than the benefit derived, especially in the case of "officiating appointments." So far as we are aware the only reason given for maintaining this rule with regard to medical officers has been that the abolition of it in their case might form a precedent for the exemption being extended to the service generally. The new regulation as regards officers joining the Staff Corps removes this objection at least, and establishes a system which ought, in justice, to be extended to the medical corps. In the British medical service an officer proceeding from one station to another, or from one appointment to another, unless in the case of an exchange between officers at their own request, is entitled to the travelling expenses of his rank, or to a free passage, and it is difficult to understand why a similar rule should not be applied to the officers of the Indian Medical Service. Important changes have within the last few years been introduced into the department in the interests of the public service, many of them by no means acceptable to the officers interested, and we do not think it is too much to expect of the Government that it should endeavour to remove the feeling of discontent which has arisen from the new arrangements by abolishing a regulation so manifestly unjust and impolitic.

THE ELECTION TO THE FELLOWSHIP OF THE ROYAL COLLEGE OF PHYSICIANS.

THE time is now approaching when the list of Members recommended for the Fellowship of the Royal College of Physicians will be submitted for the consideration of the Council. It is to be hoped that the *fiasco* of last year will not be repeated. It will be remembered that, owing to some unaccountable delay, the election had to be postponed till a later period in the year than usual, and that when the list did ultimately appear it gave so little satisfaction to the Fellows that it was referred back to the Council to be modified. The cause for this unparalleled rejection arose not so much from the sin of commission as of omission; it was probably felt that great injustice had been done in passing over the names of certain young physicians who had a decided claim to the honour on account of the services they had rendered to the profession as teachers in their respective schools, as well as having contributed to the progress of medical science by the prosecution of original research. In considering the claims of the various candidates at the forthcoming election, the first duty will be to weigh the merits of the junior members, since early election to the Fellow-

ship greatly enhances the honour, and those only should be selected who have earned a recognised position either by practical teaching, as examiners, or by original research. Next in order, the claims of the provincial members should be considered; and these of late years have increased enormously, owing to the development of many of the medical schools in the large towns. Nor should the Army and Navy be overlooked, nor the claims of some of the most distinguished physicians in our colonies be disregarded. It has been usual hitherto to elect on an average about twelve Fellows annually, but with the great extension of scientific work in the provinces and the establishment of universities in colonies, it may be a question whether this number might not be extended to fourteen or fifteen. Out of this number four Fellowships at least should be conferred on junior members as a mark of special distinction for professional work done in connexion with their hospital or the societies. Five Fellowships might be distributed among provincial members, one for each of the services, whilst three would be hardly too many to meet the requirements of India, Australia, New Zealand, Canada, and the numerous physicians practising in the large cities of Europe and America. Finally, one or two might be bestowed for other than professional work, such as for eminent service to the State, distinction in literature, or for pure science. But whatever course the Council may decide on, it is earnestly to be desired that they will carefully weigh the merits of each candidate as expressed on the nomination papers, and not disregard the recommendation of the junior Fellows with regard to election of the younger members. Above all things, a repetition of the events of last year's election must be avoided if the College desires to maintain the prestige of the Fellowship unimpaired.

GOVERNMENT PRECAUTIONS AS TO CHOLERA.

IT is evident that an organised scheme of inspection by officers attached to the Local Government Board is in progress, and that it has for its principal object to prepare sanitary authorities for the possible importation of cholera into this country in case of a recrudescence on the Continent. On the one hand, we find that Dr. Blaxall, R.N., one of the ordinary medical staff of the Board, is renewing the inspections which he commenced along the sea-coast last autumn; and on the other, it is announced that Professor de Chaumont of Netley is expected to represent the Board at some of the northern ports, and that Dr. Davies, jun., of Bristol is at work in the south, advising authorities as to the measures which they should take so as to be prepared beforehand in case cholera reaches our shores. The value of inspections such as these is very great. The comparative freedom which this country enjoys as regards diseases which are due to preventable causes is largely due to the preventive works which have been carried out during non-epidemic periods, to the sanitary improvements effected by the labours of Mr. Simon, his staff, and their successors, as also to the continuous labours of the present body of officers of health; and it is only by continuing to follow out the principle of being ready beforehand that we can expect to prevent the importation of cholera or to check its progress if it finds its way into our midst. Above all things is it necessary, first, that at all our ports there should be a sufficient staff for inspection purposes, and sufficient means for the immediate isolation of actual or suspected cases; and, secondly, that all sanitary authorities, whether in connexion with ports or inland, should similarly be prepared to deal with the sick, and should get rid of all conditions of filth in their districts which are likely to contaminate the air, water, or food of the community. After the epidemic of cholera in Egypt in 1883 the Italian Government made a number of proposals as to some concerted action on the part of the various European States, with a view of preventing the diffusion of the disease from the East; but, so far as could be judged by the ordinary Italian press, the attitude of Italy was then not such as was likely to secure the end they professed a desire to attain, and the epidemic of 1884 put the question aside for a time. But Italian views have, it is believed, undergone a material change since the proposal was first made; and it is stated that a new proposal of a similar sort has not only been made, but this country has decided to join in an international gathering by sending a delegate. The occasion may be regarded as an opportune one, for the countries in which the late epidemic so specially prevailed, have had an opportunity of learning afresh how utterly futile the sanitary cordons and allied preventive measures, on which they have hitherto relied, become in the moment of danger; and it may be that the more advanced views which have been long favoured in this country, and which have also come to be relied on in Germany, may ultimately form the basis for some general European action against the diffusion of disease.

THE INCREASE OF THE POPULATION OF FRANCE.

AT a late meeting of the Académie de Médecine, M. Rochard, who is evidently fond of statistical inquiries, read a paper on the rate of increase of the French population. Our readers may remember that in the early part of 1883 (THE LANCET, vol. i., page 417, 1883) we had occasion to draw attention to a remarkable attempt made by M. Rochard to estimate the loss in wealth that a nation sustains from such a preventable disease as typhoid fever. M. Rochard has now directed his attention to the causes of the slow augmentation in the number of Frenchmen. The French population grew at the rate of 6·30 per 1000 living at the beginning of the century, whereas the apparent increase is now represented by 3·34 per 1000; the real increase is, however, lower than this estimate, and may be put down as 2·47, a proportional rate which is even too high when emigration is taken into account; so that the actual augmentation of the French population cannot be given as more than 1·65 per 1000. This small increase cannot be explained on the ground of diminution in the number of marriages; for marriages are relatively more common now than they were in the beginning of the century. On the other hand, the number of children born in wedlock would seem to have suffered considerable diminution. This poverty of legitimate births is related to a voluntary abatement of fecundity, as well as to an involuntary loss of fecundity. The doctrines of Malthus, though not well known in France, still appear to be put in practice to a considerable extent. In the provinces the limitation of family would seem to be directly due to anxiety concerning property, whilst in towns the increase in family would lead to increased expenditure, which is so much dreaded. In the higher classes considerations of another kind present themselves. In this case the fear of the fatigue and danger to which the young mother is necessarily liable, and the altered appearances due to pregnancy, which also prevent the full enjoyment of society, seem to be the reasons for wishing to prevent increase of family. Moreover, to have many children is considered to be *mauvais goût*. The report goes on to say that France cannot be allowed to remain idle whilst other nations are in arms, for she needs children for her defence, children born of *le vieux sang français*. The upper paths of life are overcrowded, every one seeks to attain to the highest places; agriculture is deserted; peasants leave the country for the town; the rural population, which was formerly three-fourths of the whole of France, now measures barely two-thirds. M. Rochard concluded his paper by asserting that

"the evil is in our midst, and that public opinion must be brought to bear on the question." M. Le Fort considered that the Civil Code exercised some influence in causing the feeble increase of the population; for in Germany, the only province which did not increase its population was that which still retained the French Civil Code.

LEAD-POISONING.

A CASE was recently brought before Mr. Bushby, at Worship-street, which showed how unsatisfactory the Factory and Workshops Act is so far as concerns the protection it affords to men in factories where unhealthy trades are carried on. In this instance the complainant informed Mr. Bushby that he had been employed at a white-lead manufactory, and that in consequence of the owner not complying with the rules laid down in the Factory Act he had lost the use of his limbs, and that he now wanted to proceed against the owner for the damage he had received. Mr. Bushby was unable to afford the man any assistance, since he could not find that the Act was intended for the protection of men, but only of women and children. If this should prove to be the case, then the sooner the Act is amended the better. It may be all very well to say that men can protect themselves, but it often happens that the men are ignorant of the risks they run, or at least do not know how to guard themselves effectually against the dangers of an unhealthy trade. In this case it was alleged that the owner had failed to secure the attendance of a doctor to visit and examine the workmen at stated intervals, as required by the Act, so that the unhappy man, instead of having the particles of lead removed from his system before they had damaged his tissues, and at a time when treatment might have been effectual, was allowed to continue to imbibe the poison till paralysis resulted. Should such neglect to provide protective medical inspection be proved to be true, we can hardly imagine that a penalty is not incurred, and even should the Factory Act fail to reach the offender, it is to be hoped that the Employers' Liability Act would at least provide the injured man with some compensation for the terrible and lingering disease inflicted on him.

"WHEN DOCTORS DISAGREE."

ON January 19th the Ipswich Borough Coroner resumed and completed an inquiry into the cause of death of a pauper in St. Peter's Workhouse. It was alleged that the deceased woman had been struck on the head by the nurse in attendance, and the object of the investigation was to ascertain if such supposed blow had shortened the duration of life. The post-mortem examination was conducted, at the request of the jury, by Mr. Hetherington, a gentleman disinterested in the case. The body was fairly well nourished. There were two or three insignificant bruises on the limbs; there were four discharging openings on the neck. The scalp, cranium, and dura mater showed no signs of violence having been inflicted. Beneath the pia mater, on the right hemisphere of the brain, was some lymph, the result of recent meningitis. The large curvature of the stomach was infiltrated with cancerous growth, and behind the stomach were some enlarged glands, and also an abscess. The lobe of the right lung was consolidated, and the pleuræ were generally adherent. The right side of the heart was enlarged. It was an interesting and singular fact that during the lifetime of the patient the malignant disease of the stomach had not been suspected; but this may be explained by the circumstance that neither orifice of the viscus was involved. It is true on one occasion the deceased was treated for "colic," but this seems to have been the only symptom referable to the abdominal organs. It passes our comprehension why Dr. Elliston and Mr. Hetherington should have so utterly failed to agree in their opinion as to the cause of death. The former said the fatal issue was due to meningitis; the latter as strongly contended that it was the result of cancer of the stomach. It was a pity they did not recognise the relation that one lesion probably bore to the other. The proximate cause of death may have been meningitis, but surely it was not fair to exclude the antecedent conditions—suppuration in the neck and abdomen and cancer of an important organ. Every pathologist knows that in the advanced stages of malignant disease venous thrombosis is not rare; and may not the meningeal effusion have been the consequence of clotting in the convolutional veins? Again, a patient exhausted by the cachexia of carcinoma is likely to develop secondary pyæmic changes in the presence of purulent foci, such as were found in this case in the neck and abdomen. We leave without comment other points in dispute between Dr. Elliston and Mr. Hetherington, as they were not very material to the inquiry. The view of each one seems to us too exclusive, while the facts as deposed to warranted a very clear expression of opinion of the cause of death. Whether or not the discredit thrown on the nurse was merited it is not our province to decide; but it is only fair to state that from our reading of the evidence there seems no grounds for supposing that deceased succumbed to other than natural causes. The verdict of the jury, which we append, was a sensible one:—

"That the medical evidence brought before the jury being very conflicting as to the actual cause of death, we return our verdict that death arose from natural causes; and we very much regret that, owing to the great difference of opinion of the medical gentlemen, we are unable to say whether death arose from cancer or meningitis. The evidence brought before the jury has disclosed certain circumstances in reference to the death of Maria Cleveland which the jury recommend should be inquired into by the Local Government Board, and they request that the coroner should forward a copy of this recommendation to the proper authorities."

The coroner undertook to comply with the request of the jury.

SANITARY ADMINISTRATION IN IRELAND.

AT the Congress of the Sanitary Institute, which was held in Dublin in 1884, Dr. Edgar Flinn read a paper on the administration of the Public Health Act in Ireland. He explained at the onset that, with the exception of a few towns, such as Dublin (under Dr. Cameron's supervision), the Public Health Act in Ireland was a dead letter, and after making allowances for the differences between England and Ireland, both as regards wealth and other matters, he arrived at the conclusion that the principal cause of the great contrast in sanitary administration was that in Ireland the health officer was the district Poor-law medical officer, whereas in England so many officers of health are either specially skilled or give their whole time to their duties. As an ex-officer of health in England Dr. Flinn contrasted the reception given to health reports by the Irish guardians and by the English guardians respectively, in their capacities as sanitary authorities, and though he drew too rosy a picture of the English reception, at least in a number of sanitary districts, yet his statement that the Irish reports are rarely listened to and are often conveyed straight to the waste paper-basket is, we fear, but too true. As a general rule, it is a great mistake to appoint a certain number of medical practitioners to hold a health office merely because they happen to hold a Poor-law one. And not only so, but since there are nearly always several Poor-law medical officers to each union, the result is that in health matters the sanitary authority have a number of advisers scattered over different portions of their district,

instead of a single one. Owing to this circumstance alone they seek the advice of none. Where a single officer has the duty of advising an authority, a definite responsibility is vested in him, and he nearly always succeeds in performing his duty with some degree of efficiency. Without doubt, the point raised by Dr. Flinn is an important one, and it will have to be dealt with before an efficient sanitary administration is secured for Ireland. But we fear that there are other reasons than the one to which prominence is given for the laxity which obtains across the Channel. Money is scarcer there than with us, the education of the inhabitants in the rural districts has been long and sadly neglected, and even amongst many of the better classes there is not the same appreciation of the value of sanitary work as is the case in England. Ireland, too, lacks the educating element of a staff corresponding with the medical department of the English Local Government Board, and though both countries have need to make more rapid progress than they have done, yet Ireland has the largest amount of lost time to make up.

RESEARCHES ON THE NEUROGLIA OF THE RETINA OF VERTEBRATA.

IN the first part of the *Archives Italiennes de Biologie* for 1885, Dr. Joseph Sacchi gives an account of certain special investigations he has made in regard to the structure of the retina. H. Müller demonstrated before his lamented death that in all vertebrates there was a system of nucleated elements, which he termed fibres, that were sometimes disposed in fasciculi and were sometimes isolated, traversing the whole thickness of the retina from the internal limiting membrane to the external nuclear layer. He further showed that in some animals there was a second supporting system running parallel to the retinal layers. Hence he advanced as a general fact relative to the structure of the retina that in the nuclear layer the supporting apparatus formed by the radial fibres is reinforced. This reinforcement is formed partly by the radial fibres themselves, by means of lateral offshoots decussating in different planes, and in part by special elements which are isolable and belong exclusively to the nuclear layer, such special elements being particularly evident in the retina of fishes. M. Sacchi gives the results of the observations of Rivolta, Golgi and Manfredi, Rampoldi, Dogiel, and Tafani. He has himself examined the retina of Petromyzon, Esox lucius, Tinca italica; Bufo vulgaris, Rana esculenta; Tropidonotus natrix, Platydactylus mauritanus, Emys europæus, Testudo græca; Columba livia; Canis, Felix catus, Bos taurus, Equus caballus, and Cercopithecus. He appears to have obtained the best results in the case of Emys europæus, Testudo græca, and Petromyzon marinus. The eyes were quickly removed after death and placed in a 0·30 solution of osmic acid, and then into one of potassium bichromate of nearly equal strength, and finally into a chloride of sodium solution coloured with eosine. In the Emys, the anterior layers of the retina up to the neurospongium are continuous with one another, and the feet of the rods and cones are seen to be connected with the nuclei situated at different heights in the external nuclear layer. The inter-granular layer is composed of bodies of elongated and usually more or less triangular form, resembling smooth muscular tissue, but giving off branches at various points of the surface which gradually become attenuated, and after dividing dichotomously, end in extremely fine processes. Their contents are homogeneous without granulations or striæ, and there is no trace of a nucleus. Their length varies between 65 μ and 97 μ, and their diameter between 3 μ and 5 μ. The successive layers of the retina in Emys europæus are, then, as follows:—The rods and cones, presenting an external limb, a coloured droplet, an intercalated portion and an accessory portion; an external limiting membrane; the outer granule layer or large visual cells of Dogiel with large basal cellules; the intergranule layer; the internal granule layer with the fibres of Müller and nerve cells situated alongside the neurospongium, constituting the spongioblasts of Müller; the neurospongium; the ganglion cell layer; and, lastly, the layer of optic nerve fibres.

THE POWERS OF WATER COMPANIES.

IN a special report which has been submitted to the Kensington Vestry Dr. Dudfield draws attention to a case in which twenty separate business premises in a mews in his district were suddenly deprived of their water-supply by the action of the Grand Junction Waterworks Company, who severed the service pipes to the several premises because the landlord had failed to pay the water-rates. In this case the landlord's default to make the proper payment seems to have been inexcusable; but Dr. Dudfield refers to the case mainly with a view of showing how needlessly extensive and arbitrary are the powers with which water companies are vested in this matter. Not only can groups of houses be thus suddenly deprived of one of the necessaries of health and life, but if any neighbours or friends were to give those persons whose water has been cut off a supply from their own service pipes, or were to allow them to take enough for their needs, they would render themselves liable to penalties of ten pounds and five pounds respectively; whereas the company could, without resorting to so extreme a measure, recover the rent for water by an ordinary legal process. It is true that in the case in question the company, after the matter had been made the subject of public comment, fixed a stand-pipe in the mews, and so prevented an actual water-famine; but it seems clear that water companies have in this and allied respects powers which are much in excess of those which should be granted to bodies having a monopoly of one of the requisites of life, and we are glad to observe that all the details of the case have been brought under the notice of the Local Government Board, of the Home Secretary, and of the Royal Commission on the Housing of the Working Classes.

DEGENERATION AMONGST LONDONERS.

THE lecture delivered last week by Mr. James Cantlie on "Degeneration amongst Londoners" was received with approval not unqualified by dissent. The address, while true to the concentrated life of many large towns besides London in its general tenour, might be said to be a diagrammatic, or rather a scenic, portrayal of that life. Some of its statements could hardly be received without a qualifying grain, as that, for instance, which declared a pure Londoner of the fourth generation to be impossible. It dealt principally, moreover, with the poorest class of town dwellers, among whom the struggle for existence is seen in its rudest and acutest phase. This fact, no doubt, has served to heighten the colour of the picture. At the same time, it must be admitted that the variation is rather one of shade than of contour, and arises not unnaturally from the necessities of illustration which belong to the subject in question. He who would find the centres of decay in a nation, still on the whole robust and active, must seek for them at the points of social tension. The proofs of pressure, starvation, and atrophy, of vice and of brutal reversion, and of their results are all to be found here. The beginnings of the same process may be watched and often remedied in other grades; in this class, one frequently sees the beginning run on to its end in a single generation. Mr. Cantlie is not disposed to let this happen. He does not speak as a mere melancholic or idle image breaker, but as a practical healer of abuses. His means of cure are two: fresh air and exercise. With regard to the vital importance of each of

these to all normally formed persons there can be no question. The existence of various well-known societies and committees for the direct promotion of wholesome living is evidence enough to this effect. The subject for consideration rather is, how to bring these necessary luxuries—for so they must now be described—within reach of the many who have them not; and for the solution of this problem no answer which is not practical is worth having. Any such answer must of course affect the working of our whole civic system. Work, means, and food, the regulation of working time so as to allow of a fair measure of personal leisure and of sleep, are equally matters of the first significance, and may be said to form in many cases the standing ground required for the operation of all other remedial measures. We have good hope that the national mind, recognising that there is degeneration and that it is curable, will continue to treat it with sympathy, as it has begun to do, and will direct upon it the fresh air of public discussion and the healthy exercise of a wisely corrective legislation.

MILK EPIDEMIC IN THE STATE OF NEW YORK.

DR. F. C. CURTIS gives an instructive account in the Fourth Annual Report of the State Board of Health of New York on a sudden outbreak of enteric fever at Port Jervis in the autumn of 1883. Isolated attacks occurred at intervals from October 1st to the 15th, on which latter day a batch of six cases was reported; eleven attacks took place in the two days, October 24th and 25th; nine, seven, and eleven more were recorded on the next three days, and at intervals up to November 12th the fresh cases averaged some six a day, after which date a subsidence set in, the last case occurring on Dec. 24th. Port Jervis contains a population of about nine thousand inhabitants, and 148 cases of enteric fever occurred amongst them. Previous to the occurrence, the locality had the reputation of being healthy. The outbreak arose, suddenly and subsided with similar rapidity; it was limited to Port Jervis. There were apparently no special foci of infection, the disease being distributed here and there without any special reference to sanitary or other local circumstances; and a comparatively large proportion of the members of each infected family were attacked. By a process of exclusion, Dr. Curtis eliminates many of the ordinary causes of enteric fever distribution; and he then points out that, whereas there were some twelve milk vendors in the place, nearly all the cases occurred amongst some 500 who received their milk from one special vendor; indeed, out of the total of 148 cases, 128 took this special milk. A portion of the milk delivered by the dairyman in question came from a farm in the Neversink valley, and on inquiry it transpired that enteric fever broke out in the family residing there in the previous August, and was still prevalent at the date when Dr. Curtis made his inquiry into the circumstances of the epidemic. After ascertaining all the arrangements carried out in the dairy, Dr. Curtis came to the conclusion that three ways were open for the infection of the milk. In the first place, the well on the premises might have become infected from the deposit of the excreta and the bath water. The infection might also have reached the milk cans either directly by means of the infected air of the premises, or by reason of the cloths used for cleansing the cans, these cloths being at times hung up to dry in a place having direct aerial communication with an infected apartment. And, lastly, it was possible that those coming in contact with the sick might have conveyed infection directly to the milk, owing to the part they took in the dairy operations. Under any circumstances, the milk was not only liable, but almost certain, to receive infection under the operations carried out at the dairy farm. Milk contamination fully accounted for the fact that of those attacked by the disease 87 per cent. were persons supplied by the one dairyman; and it also explained the circumstance that no other cause of disease except milk infection could be ascertained to exist in the place. The discovery of milk as the source of infection also led, by the suspension of the supply, to the cessation of the outbreak. In this dairy farm it is stated that "at least ordinarily scrupulous care" was taken in the handling of the milk. This is often the case when disease follows in the track of the milkman; and it seems quite evident that no such supervision of dairy farms or milk-shops as can in practice be carried out suffices to eliminate all possible sources of infection. Those who drink cooked milk only have invariably escaped milk infection even when subjected to the same influences as those who have been attacked; and each fresh milk epidemic tends to prove that safety against infection can only be secured by the boiling or cooking of all milk used for domestic purposes.

NUISANCE FROM BRICK-BURNING.

THE Society of Medical Officers of Health have recently had under consideration the very general complaint which has been made in the outskirts of the metropolis as to the nuisance arising from the process of brick-burning. During the sultry weather of last summer many persons, it is alleged, were compelled to get up in the night to close their windows against the offensive effluvia, and the Council of the Society express the opinion—first, that there are sufficient reasons for regulating this trade by bye-laws, as other offensive trades have been, with such manifest advantage to the public; and, secondly, that owing to the considerable distance which these effluvia travel, and to the fact that many of the brickfields contributing to the nuisance are outside the metropolitan area, legislation should be general, and apply to areas within a specified distance of centres of population. With the general conclusions arrived at we fully concur, for at present one of the most offensive trades to which towns are subjected is carried out quite regardless of the large amount of discomfort which it occasions to the populations living in the vicinity of the works.

THE LATE REV. DAWSON WILLIAM TURNER, D.C.L.

ON the 29th ult. there died in Charing-cross Hospital, of which institution he was an honorary life governor, a man who, though not a member of our profession, was in deep sympathy with it, and who in some respects was a very remarkable personage. The work of the last ten years of his life chiefly concerns us now, and it may suffice to tell here that Dr. Dawson Turner was the son of the well-known banker of that name in Yarmouth. He was a demy of Magdalen College, Oxford, took deacon's orders, and after some years became head master of the Royal Institution School, Liverpool. Here he did excellent work, and had a succession of distinguished pupils. On resigning his head mastership, he settled in London, and followed with much interest the practice of the surgeons in the out-patient departments of several of the hospitals, notably at Westminster and Charing-cross. He wrote a pamphlet, entitled "Hints and Remedies for the Treatment of Common Accidents and Diseases, and Rules of Simple Hygiene,' which has passed through nine editions. In preparing this he was careful to secure assistance from several of his friends and old pupils in the profession. He was a constant contributor to the Press on subjects connected with hospital management, and was especially interested in securing supplies of books, newspapers, and clothing for the inmates of many of the London hospitals. He visited the wards of one or two hospitals regularly, recited poetry to the patients, listened to their tales of distress, and ministered both to their bodily and spiritual welfare. Spending next to nothing

on himself, he did good by stealth, and none appealed to him with a worthy claim in vain. In addition to several excellent classical works, including his well-known "Notes on Herodotus," he issued a capital series of Analyses of Greek, Roman, English, and French History, and Grammars of the French, German, and Italian languages. His interest in matters medical was dated from an early period, when a schoolfellow of Sir James Paget's; and he was naturally proud of his nephew, Sir Joseph Hooker. Amongst his numerous pupils were the present Bishop of Ripon, Sir George Campbell, Canon Duckworth, and Professor Warr of King's College; he also claimed Dr. Dyce Duckworth and Mr. Thomas Pick amongst these. His only son is now studying medicine in the University of Edinburgh. Dr. Turner was seized with left hemiplegia in the Strand on the 17th ult., and was taken to Charing-cross Hospital. He rallied to some extent, but succumbed to an attack of facial erysipelas, from which he had twice previously suffered. He was in his seventieth year. A friend of the friendless, a humble follower of his great Master, all who knew him are left the poorer by his death—certain, however, that he had well done his work and left a noble example behind him. Of him it may truly be said—"Exstinctus amabitur idem."

THE MEMBERS FOR SOUTH-EAST LANCASHIRE AND THE VACCINATION QUESTION.

IT is curious to watch the dilemma of a member of Parliament with an honest and intelligent mind betwixt the clear duty of upholding vaccination as the greatest boon conferred on humanity by Medicine, and the desire to conciliate the fanatics who see in it nothing but a means of mischief. A case in point occurred on Saturday last, when Mr. Leake and Mr. Agnew were confronted with the anti-vaccinationists. The members stood fairly well to their convictions as regards the propriety of making primary vaccination compulsory; but they might with a little more trouble have easily made out a much stronger case, and might have reminded their well-meaning but unintelligent constituents that within the last few weeks one poor man in London has paid dearly for his breach of this most beneficent law by the death of three unvaccinated children. Mr. Leake's reasoning on the question of compulsory revaccination was a little peculiar. He seems to have had a very remarkable experience on this point. We had better quote his own words: "As for revaccination, his experience of it was so serious and costly—the revaccination of his household in London a few years ago had cost him between £50 and £70—that in the future he would take any risk rather than have the operation done again." Such an unusual and unfortunate experience can be no argument against a system by which the operation would be done for the people for a trifling sum at the public expense. But though we can neither understand nor defend the cost of Mr. Leake's revaccinations, we can assure him that one case of small-pox—even a mild one in his family in the middle of a London season—would be a more costly, serious, and annoying business than even such a bill for revaccination. Mr. Agnew found it equally difficult to be unfaithful to the overwhelming case for vaccination and to resist the enthusiasm of its opponents. He held out a vain hope that, as medical men had given up bleeding, they might one day give up vaccination, and enable members of Parliament to make discreditable pledges to its opponents. Mr. Agnew is not likely to be thus helped out of his perplexity. We are nearing the centenary of the scientific demonstration by Jenner of the protecting virtue of vaccination. Under its influence, well repeated, but not indefinitely repeated, small-pox nurses live with absolute impunity in small-pox hospitals, repeating and confirming Jenner's demonstration to all who have eyes to see. The century is a critical one; but, so far from abolishing vaccination, it is extending the principle embodied in it to other diseases, and science is only grieved that it cannot do so more extensively. Public men will be well repaid, and will do an infinite public service, in informing themselves on this great question, and in courageously stating the teachings of science and of common sense.

TUMOURS OF THE PITUITARY BODY.

PATHOLOGICAL anatomy affords abundant illustration of the principle that morbid action is prone to occur in tissues and organs which have ceased to take any important share in the physiology of the economy. At the Pathological Society on Tuesday last the members were treated to an inspection of several new growths of the pituitary body. The development of the hypophysis cerebri, or pituitary body, as it is commonly called, has been the subject of considerable controversy amongst embryologists. Von Baer and Schmidt taught, in 1862, that the whole of the gland was developed at the expense of the infundibular process at the floor of the third ventricle. In 1838 Rathke stated that a diverticulum from the upper end of the alimentary canal shared in the formation of the hypophysis. Dursy made the pituitary body to be formed out of the end of the notochord, as well as of the epithelium of the alimentary tract. Reichert at first believed this structure to be developed from the remains of the front end of the notochord, but later on he considered that the pia mater was chiefly involved in its formation. Rathke also modified his earlier views, and came to believe that the diverticulum of the alimentary canal disappeared, and that the hypophysis cerebri was developed from a portion of the mesoblast, in front of the clinoid process. Wilhelm Müller wrote an elaborate memoir on the development of the pituitary body, in which he made out that a hypoblastic diverticulum from the upper end of the alimentary tract joined the infundibulum from the third ventricle. Götte and others, however, believe that the epiblast of the stomodæum is concerned in the formation of the diverticulum which goes to meet the infundibular process, and this was the view which Mr. J. B. Sutton adopted at the discussion on Tuesday night. The excellent specimens of the myoneuroma shown by Dr. Hale White contained abundant nerve cells and striped muscle fibre. The mesoblast around the upper end of the alimentary tract is no doubt the source of these striped muscle fibres, and the explanation proffered by Mr. Sutton that a larger amount than usual of nipping off of the epiblast took place is very reasonable, though it seems to us hardly necessary, seeing that it is almost impossible for an epithelial diverticulum to be formed without including some of the mesoblast which invariably surrounds it. All that is requisite to suppose is that this mesoblast underwent an unusual development.

THE USE OF CARBOLIC ACID IN PURULENT AFFECTIONS OF THE CONJUNCTIVA AND CORNEA.

DR. BURNHAM of Toronto, in a paper published in the *American Journal of Ophthalmology*, strongly advocates the use of a 5 per cent. solution of carbolic acid in gonorrhœal ophthalmia, especially in those cases where there are deep transparent excavations. In such cases he directs the patient to be kept in bed; a large basin of cold water, cooled by ice, is placed at the bedside. With this the eyes are to be frequently bathed, whilst cloths wetted with it are to be kept on the lids. The 5 per cent. solution of carbolic acid is to be thoroughly applied every hour. It produces but little pain, and by degrees it is to be exchanged for a 2½ per cent. solution. It acts as an antiseptic and astringent. Dr. Burnham finds it effective in cases of kerato-iritis.

CONVOCATION OF THE UNIVERSITY OF LONDON.

THE adjournment of Convocation to the 3rd instant enabled it to get through the long agenda list which was submitted at the January meeting. A motion by Mr. F. W. Aveling, urging greater limitation in the sphere of examination in Greek and Roman history at matriculation was after discussion referred to the annual committee. It was also resolved that the scriptural examination should be thrown open to all graduates; and another motion, requesting the Annual Committee to frame a scheme for promoting the formation of a union "which should aim at bringing members of the university into frequent friendly and intellectual intercourse," was also carried. Some debate arose upon a proposal that in the selection of examiners preference should be shown to London graduates, and ultimately this was lost by a considerable majority. It was also resolved that Convocation should meet at least three times annually. In the course of a debate upon the D.Lit. degree, the Chairman stated that changes were about to be made in this examination and in that of the D.Sc.—the basis of which is the recognition of original work in higher literature or science as qualifying for the degrees. The rest of the business referred to the M.A. degree, including the passing of a resolution recommending that modern languages be made a branch of that examination.

SANITATION AT WOOLWICH.

IT is strange that Woolwich, an important garrison town, should not only be without a medical officer, but that the local board of health, which by the way until very recently did not number a single medical man among its members, should be strictly within its legal rights in omitting to appoint an officer. The way in which this legal hiatus came about was this: Woolwich was included in the Metropolis Local Management Act of 1855, but by a saving clause the new powers and duties conferred upon metropolitan local boards were not extended to Woolwich; and, on the other hand, this parish is not subject to the Public Health Acts of 1872 and 1875, so that it could only appoint a medical officer under a permissive provision of the Public Health Act of 1848. But the local wiseacres misunderstanding the objects and duties of a medical officer, and the town happening to have been free for some years past from any serious epidemic, maintained that such an officer is quite superfluous. The Local Government Board Inspector, Mr. Spear, who has just issued a report upon the "Sanitary Condition and Administration of the Local Board District of Woolwich," is of a very different opinion. He points out that it is impossible, without the supervision of a skilled medical officer of health, to deal satisfactorily with the overcrowding, infectious disease, unhealthy houses, nuisances, &c., which he found to exist.

DEATH OF DR. W. STORY.

AN inquest was held on the 27th ult. on the body of Dr. William Story, who died somewhat suddenly at his residence at Linslade on the previous night. A verdict of death from natural causes was returned. It will be within the recollection of our readers that at the winter assizes held at Bedford in October, 1881, Dr. Story was convicted on a charge of arson, and sentenced by Mr. Justice Matthew to five years' penal servitude. There being strong reasons to believe that the offence was committed while the prisoner was in a state of insanity, strenuous efforts were made to obtain a remission of the sentence, and a petition was sent to the Home Secretary praying for a mitigation of the punishment. This petition we published in our issue of June 24th, 1882, remarking that if the facts therein stated were correct, the case was one not for suit but for remonstrance. Towards the end of 1883 (we think in October) Dr. Story was released from prison and returned to reside at Linslade, where, as above stated, he died on the 26th ult., aged seventy-two years. He had been seriously ill from time to time after he returned home. We regret to learn that Mrs. Story is left quite destitute; she is sixty-six years of age, and her grievous troubles of the last few years have so impaired her health as to incapacitate her from earning her livelihood. We therefore venture to appeal to our readers on her behalf. Mrs. Story's address is Wing-road, Linslade, Leighton, Beds.

LUNACY REFORM AND POOR-LAW MEDICAL OFFICERS.

AT a meeting of the Council of the Poor-law Medical Officers' Association, held Feb. 3rd, attention was drawn to the proposed Lunacy Law Amendment Bill, from which it would appear that in future Poor-law medical officers will be debarred from examining lunatics, and that such duty will be vested in medical officers of health, the family medical attendant, and superintendents of asylums. It was resolved, "That this Council feels strongly that such a step would throw an undeserved slight on the 3500 Poor-law medical officers of England and Wales. The Council sincerely trust that every Poor-law medical officer in his respective district will at once place himself in communication with his representative in Parliament, so that such Bill may be amended when in Committee."

THE CARRIAGE TAX.

THERE is an earnest and commendable endeavour in progress to promote the abolition of the carriage-tax. Medical men who use carriages chiefly for professional purposes are much interested in the accomplishment of this reform. It is thought that if the tax were abolished there would be a considerable increase in the number of carriages kept, if not in the number of persons keeping carriages. We venture to doubt the accuracy of this conjecture; but, be that as it may, in so far as this burden of taxation falls on the shoulders of those who use carriages for business purposes, it is an impost on industry. Looking at the matter in this light, we are entirely with the promoters of the movement, and they have our warm sympathy.

THE HOSPITAL SATURDAY FUND.

THE eleventh annual meeting of this Fund, under the kindly presidency of Mr. Samuel Morley, was recently held. The promoters, on the motion of Mr. Lucraft, pledged themselves to do all they could to increase the number of collections in workshops. The Workmen's Convalescent Home, St. Margaret's Bay, near Dover, was alluded to with reasonable satisfaction by the President, who offered £400 towards defraying the debt of £2000 remaining on the Home if others would provide £1600. This would enable the committee to receive 100 more patients. Mr. Morley's offer should meet with a hearty response.

BOARDING-OUT OF PAUPER CHILDREN.

MISS ANNETTE PREUSSER complains, in a letter to *The Times*, of the unfairness to those who believe in the boarding-out of pauper children of the action of the Local Government Board. The Board objects to appoint a general inspector of such children because only a thousand are so boarded, and the board of guardians are not allowed to visit and inspect for themselves. We think there is enough evidence in favour of this system to entitle it to a little more encouragement from both guardians and the Local Government Board.

WATER-SUPPLY IN THE ORMSKIRK RURAL DISTRICT.

THE need for a proper water-supply for Burscough Bridge in the Ormskirk rural district has for some time past been under discussion; the existing wells are polluted, and a culvert by the canal which is resorted to is apt to fail in dry weather, and is liable to be fouled by filth deposited by the occupants of boats and barges. When the sanitary authority recently made a move towards procuring a proper supply, they were met by the resolution of a meeting of ratepayers opposing the scheme on the ground of expense; and, apparently fearing to do anything in opposition to these people, the matter is to be allowed to drop. No such resolution can, however, relieve the sanitary authority from the duty it has of seeing that the inhabitants of its district are provided with a proper water-supply, and for any ill results which may ensue in consequence of their failure to make such provision the authority will primarily be responsible.

PROPOSED EXTENSION OF THE ROYAL SURREY COUNTY HOSPITAL.

WE are glad to hear that more than £1700 have already been promised towards the sum of £6000 required for the carrying out of the above desirable proposal. The annual meeting of the governors of the hospital (the president, the Bishop of Winchester, in the chair) will be held on the 28th instant, and we trust on that occasion many additional names with substantial sums attached to them will be added to the subscription list. It would seem advisable that the larger towns of Surrey, especially Guildford, where the hospital is situated, should be actively canvassed with a view to securing small contributions. Not only does "Mony a little mak' a mickle," but it is very desirable that those classes who enjoy the benefits of the hospital should at least have their attention directed to this present opportunity of expressing their gratitude to, and appreciation of, such an excellent institution. Contributions, we may add, will be gladly received by the Treasurer, R. J. Shepard, Esq., Guildown House, Guildford, and by the Assistant Secretary, T. Taunton, Esq., at the hospital.

THE MEDICAL SOCIETY OF LONDON.

THE last Lettsomian lecture was delivered by Dr. Lauder Brunton at the meeting held at the Medical Society's Rooms on Monday last. At the conclusion of the lecture, Dr. Hare proposed, and Dr. Milner Fothergill seconded, a cordial vote of thanks to Dr. Brunton, expressing a wish also that the lectures would be published for the benefit of the profession at large. The vote was passed with acclamation. Elsewhere we have drawn attention to the salient features of these lectures. Next Monday night Mr. Henry Morris will read a paper on Some Points in the Surgery of the Kidney, and an important discussion is anticipated.

THE CASE OF FREDERICK MARSHALL.

THE *St. James's Gazette* is mistaken in supposing that because Frederick Marshall has been sent to Broadmoor as a "lunatic" he is placed there for life without trial. The prisoner is only in the position of an accused person under remand until such time as he can "plead" to the charge against him. If he should recover, he will be put on his trial. If not, he will remain under remand. He could not be better placed in any asylum in the country, and he will be most justly and humanely cared for by those to whose custody he is entrusted. While he is insane he cannot possibly plead "guilty" or "not guilty" to an indictment which is simply suspended—not either quashed or adjudicated upon.

HOSPITAL ELECTIONS.

THE principle of purity of election has just been successfully asserted at the Royal Alexandra Hospital for Sick Children at Brighton. A vacancy having occurred in the office of house-surgeon, fourteen candidates applied. The medical committee sent up to the committee of management the names of three, and recommended one of the three (Mr. Morgan) for selection, he being, in their opinion, the candidate possessing the highest testimonials. The committee of management elected Mr. Morgan. This result redounds greatly to the credit of the majority who voted for him. Mr. Morgan was a perfect stranger, and was not indebted in any way to local influence or patronage for his success. If local institutions generally adopted the above principle, there would always be a plentiful supply of highly qualified candidates for vacant offices. Mr. Morgan was a student of Charing-cross Hospital, where he greatly distinguished himself.

DR. KLEIN ON THE CHOLERA BACILLUS.

AT the meeting of the Royal Society on Thursday last Dr. Klein read a paper on the Relation of Bacteria to Asiatic Cholera, and showed clearly that the "comma bacillus" of Koch does not behave differently in cultivation from the similarly shaped organisms found by Lewis in the mouth and by Deneke in cheese. On many other points—e.g., as to the presence of the organisms in the intestinal mucosa, the action of acids upon their development, &c.—Dr. Klein has arrived at results entirely opposed to those of Koch; and he explains some of these divergences by the difference in time at which the post-mortem examinations have been made. The English Commission made the examinations as early as possible after death, and found that the "comma bacilli" increased in number *pari passu* with the length of time that elapsed between death and the examination. We must defer fuller notice of Dr. Klein's paper till next week.

THE PROPOSED TEACHING UNIVERSITY FOR LONDON.

THE second meeting of the members of the Association for promoting a Teaching University was held on Thursday, the 5th inst., at the Society of Arts, and an Executive Committee was appointed to reconsider the report issued by the provisional committee, to enter into negotiation with the different representative bodies, and to ascertain how far the authorities of the existing University of London were prepared to adopt the main suggestions of the Association. Lord Rosebery has consented to succeed Lord Reay as Chairman of the Association. The Committee includes, amongst others, Professor Marshall, and Drs. Ord, Pye-Smith, and Norman Moore.

CORPORAL PUNISHMENT ON BOARD TRAINING SHIPS.

IN reference to the complaint of excessive corporal punishment of boys on board the *Northumberland*, the following letter has been received from Sir Thomas Brassey, M.P., Secretary to the Admiralty, in answer to a communication from the Society for the Prevention of Cruelty to Children:—

"Admiralty, Whitehall, Jan. 29th, 1885.

"DEAR SIR,—In reply to your letter of the 2nd inst., I have to state that the circumstances have been investigated, and that steps have been taken to prevent the recurrence of the frequent caning of boys which has occurred on board the *Northumberland*.—Most faithfully yours,

(Signed) "THOMAS BRASSEY.

"Dr. D. Buxton, Secretary, London Society for the Prevention of Cruelty to Children, 7, Harper-street, Bloomsbury, W.C."

AT the usual meeting of the Metropolitan Asylums Board on the 31st ult., a letter from the Admiralty was read, stating that if the managers wished to keep the ships *Atlas* and *Endymion*, which were lent some years ago by the Admiralty on an emergency to meet the outbreak of infectious disease, they must be paid for, the *Atlas* being valued at £3400 and the *Endymion* at £6500. It was unanimously resolved that an answer be sent to the effect that the managers would purchase the vessels; but that, having regard to the fact that the managers were the administrators of poor rates, they would be glad if the Admiralty could see their way, after further consideration of all the circumstances of the case, to reduce the amounts named.

AT the request of the committee formed for the establishment of a British Hospital at Port Said, who met for the first time on the 31st ult., Lady Strangford has issued an appeal for funds for building purposes. A site for the hospital was given some years ago; a plan, suited to the climate, of a compact, one-storeyed building, to hold forty beds, has been approved; the furniture, linen, &c., are on the spot waiting to be used; and, most important of all, a sufficient income for the maintenance of the hospital is secure. All that is needed is money for the structure itself. The object is a good one, and we trust that Lady Strangford's request for assistance will not be made in vain.

THE front page engraving of the *Animal World* for Feb. 1st depicts the inside of the accident ward of Charing-cross Hospital, and Mr. Dodson, the house-surgeon, engaged in bandaging the leg of the injured dog, whose sagacity was a theme of comment, a short time ago, in almost every newspaper in the kingdom.

WE have great pleasure in calling the attention of our readers to the resolutions passed at a meeting held on the 15th ult., and reported on another page, in reference to the proposal to mark, by a suitable memorial, public and professional appreciation of the important services rendered by Dr. Maclean, C.B., during his tenure of the chair of Military Medicine at Netley, a post which he is about to vacate.

THE *Opinione*, the leading journal in Rome, announces that on the 1st inst. an illustrious guest *(ospite illustre)*, in the person of the celebrated English naturalist, Prof. T. H. Huxley, President of the Royal Society of London, assisted at that day's sitting of the Royal Academy of the Lincei, of which he is Corresponding Fellow.

THE *Demerara Daily Chronicle* records the death, on December 27th, of Dr. Cameron of Georgetown. The deceased was health officer of the port, chairman of the Board of Poor-law Commissioners, and health officer of the city, and was greatly respected in the colony, where he had practised for over a quarter of a century.

DR. EUGÈNE BODICHON, known chiefly in connexion with his efforts to bring into notice the febrifuge qualities of the Eucalyptus globulus, died on the 28th ult. at Algiers, aged seventy-four.

PROFESSOR GUIDO BACCELLI has been elected President of the Royal Academy of Medicine of Rome.

AT Hull on the 2nd inst., a man was fined forty shillings and costs for having exposed his son whilst suffering from small-pox.

ARMY MEDICAL SCHOOL AT NETLEY.

THE winter session of the Army Medical School terminated on the 2nd inst., when the prizes were distributed before a large company assembled in the lecture-room of the Royal Victoria Hospital, Netley. The War Office was represented by Dr. Crawford, LL.D., Director-General of the Medical Department of the Army; and the India Office by Sir Joseph Fayrer, K.C.S.I., Physician to the Council of India. At the invitation of the Senate of the School, Sir James Paget, F.R.S., presented the prizes to the successful competitors.

The names of the surgeons on probation who passed successfully through the course of special instruction for the medical departments of the British and Indian services, a list of whom will appear in our next, were read by Surgeon-General Longmore, C.B., together with the reports of the results of the examinations, intended for the information of the Secretaries of State for War and India.

Sir James Paget then distributed the awards, accompanying each with appropriate remarks to the recipient, and afterwards delivered an eloquent address to the young military surgeons, which occupied half an hour, and was listened to throughout with the most marked attention by the whole assembly. The text of the discourse may be said to have been a survey from a civilian's point of view of an army surgeon's professional career and responsibilities under the peculiar circumstances incidental to military life, especially when on active service in the field, and a comparison between them and the career and responsibilities of a surgeon in a large sphere of civil practice. A hope was strongly expressed by many present that Sir James Paget would consent to his address being hereafter published *in extenso*.

The Director-General, after a few well-chosen remarks on the address delivered by Sir James Paget, added his congratulations and best wishes to the young surgeons who were just entering the ranks of the public service. The business of the session was then closed, and the company were subsequently entertained at luncheon by the principal and other medical officers in the spacious mess-room of the officers' quarters in the hospital.

THE MACLEAN MEMORIAL.

AT a meeting held on the 15th ult., at the residence of Surgeon-General Sir Joseph Fayrer, K.C.S.I., the following resolutions were unanimously adopted:—

1. Proposed by Director-General T. Crawford, M.D., and seconded by Deputy Surgeon-General J. A. Marston: "That a representative committee, composed of members of the Public Medical Services, be formed for the purpose of taking steps to mark by a suitable memorial their high appreciation of the distinguished services of Professor W. C. Maclean, C.B., M.D., on the occasion of his retirement from the chair of Military Medicine in the Army Medical School at Netley."

2. Proposed by Surgeon-General Sir Joseph Fayrer, K.C.S.I., seconded by Surgeon-General W. A. Mackinnon, C.B.: "That the following gentlemen be requested to act as a provisional committee for the purpose of carrying out the foregoing resolution, with power to add to their number: Surgeon-General Sir Joseph Fayrer, K.C.S.I., Bengal Medical Service (retired); Surgeon-General Sir W. Guyer Hunter, K.C.M.G., Bombay Medical Service (retired); Surgeon-General W. A. Mackinnon, C.B., Army Medical Staff; Inspector-General of Hospitals H. Macpherson, Bengal Medical Service (retired); Inspector-General J. D. Macdonald, F.R.S., Naval Medical Service; Deputy Surgeon-General J. A. Marston, Army Medical Staff; Surgeon-Major J. L. Paul, Madras Medical Service; Brigade Surgeon H. Cayley, Bengal Medical Service; Fleet-Surgeon Walter Reid, Naval Medical Service; Surgeon-Major K. McLeod, Bengal Medical Service; Secretary and Treasurer—Surgeon-Major K. McLeod; Bankers—Messrs. Grindlay and Co., 55, Parliament-Street, London, S.W."

3. Proposed by Surgeon-General W. A. Mackinnon, C.B., seconded by Brigade Surgeon H. Cayley: "That the amount of subscription be limited to £1 1*s*."

4. Proposed by Surgeon-General Sir Joseph Fayrer, K.C.S.I., seconded by Surgeon-Major K. McLeod: "That the proposed memorial take the form of a portrait of Professor

Maclean, to be hung on the walls of the Netley Hospital, and that, if funds permit, a replica of the portrait be presented to Mrs. Maclean."

WILLS OF MEDICAL MEN.

THE will and codicil of Thomas Wright, M.D., F.R.S., late of 4, St. Margaret's-terrace, Cheltenham, Gloucestershire, who died on Nov. 17th last, has been proved by Thomas Lawrence Wright, the son, Joseph Wethered, and William Henry Paine, M.D., the executors, the value of the personal estate in the United Kingdom exceeding £25,000. The testator makes special gifts to each of his children, including the house and premises, 4, St. Margaret's-terrace, to his said son, and there are legacies to his sons-in-law and to a servant. One-third of the residue of his property he leaves to his said son, and one-third upon trust for each of his daughters, Mrs. Wethered and Mrs. Wilcox.

The will of Joseph Luke, M.D., late of Oak Lodge, Green-lanes, Finsbury-park, who died on the 22nd of October last at Hastings, has been proved by Robert M'Clure and Charles Frederick Elsten, the acting executors, the value of the personal estate amounting to over £8000. The testator leaves all his property upon trust for his wife for life, and then for his five children.

The will of Andrew James Scott, M.D., formerly Surgeon in the Madras Army, and of Tiverton, Devon, but late of 4, Anglesea-terrace, St. Leonards, who died on October 21st last, has been proved by William Collier Angove, Mrs. Emma Scott, the widow, and Captain William Augustus Scott, the son, three of the executors, the value of the personal estate exceeding £6800. The provisions of the will are in favour of the testator's wife and daughters and his said son and his children.

The will of John Dan Brown, M.D., late of Rochester, Kent, who died on October 23rd last, has been proved by Arthur Tresco Franklyn Brown, Physician and Surgeon, the son and sole executor. Subject to a legacy to his housekeeper, the testator leaves all his real and personal estate to his said son.

The will of Charles Blakeley Brown, M.D., late of 3, Hill-street, Berkeley-square, who died on October 22nd last, has been proved by Mrs. Emila Brown, the widow and sole executor, the value of the personal estate amounting to over £15,000. The testator devises and bequeaths all his real and personal estate to his wife absolutely.

The will and codicil of Edward Thomas Roe, M.D., late of 18, Kensington-crescent, who died on September 28th last, was proved on the 18th ult. by William Hobbs, the sole executor, the value of the personal estate exceeding £4400. The testator leaves all his furniture and effects and an annuity of £200 to his wife, Mrs. Sarah Roe, and the residue of his property to his two daughters.

The will and two codicils of Mr. James Alexander Guise, Inspector-General of Hospitals, retired, late H.M. Bengal Medical Service, formerly of Elm Grove, Elgin, Scotland, but late of The Knoll Leigh Woods, Long Ashton, Somersetshire, who died on October 4th last, were proved on December 23rd last by Charles Guise, the brother, John Fullerton Beatson, M.D., C.I.E., and Miss Mary Ann Georgina Guise, the daughter, the executors, the value of the personal estate exceeding £4600. The testator leaves legacies to his executors and an annuity to his brother, Francis George. The residue of his property is to be held in trust for his wife, Mrs. Mary Jane Guise for life, then for his daughter, Mary Ann Georgina, so long as she shall remain unmarried, and then for his said daughter and his son, James John.

The following legacies have recently been left to hospitals and other medical institutions:—Mr. Benjamin William Benson, of 2, St. Leonards-terrace, Chelsea, £100 to the London Hospital, Mile-end-road; Mr. Edmund Burke, of 85, Avenue-road, Regent's-park, Barrister-at-Law, £500 to the Cottage Hospital, Walsall, near Birmingham; and Mrs. Elizabeth Lewis, of Nightingale Villa, Clevedon, all her shares and interest in the Clevedon Gaslight Company to the Clevedon Dispensary, and all her shares, stock, and interest in the Clevedon Waterworks Company to the Clevedon Cottage Hospital.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 6020 births and 4188 deaths were registered during the week ending the 31st ult. The deaths showed an increase of 96 upon the number returned in the previous week, and were equal to an annual rate of 24·5 per 1000 of the estimated population of these towns in the middle of this year, against 24·2 and 24·0 in the preceding two weeks. During the first four weeks of the current quarter the death-rate in these towns averaged 24·4 per 1000, against rates declining from 27·7 to 21·1 in the corresponding periods of the six years 1879-84. The lowest rates in these towns last week were 13·5 in Birkenhead, 17·6 in Salford, 18·0 in Derby, and 19·0 in Hull. The rates in the other towns ranged upwards to 30·2 in Plymouth, 32·7 in Preston, 34·9 in Cardiff, and 36·6 in Norwich. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 370 and 372 in the previous two weeks, further rose to 386 last week; of these 141 resulted from whooping-cough, 58 from measles, 56 from scarlet fever, 43 from "fever" (principally enteric), 35 from diphtheria, 32 from diarrhœa, and 31 from small-pox. The lowest death-rates from these diseases, in the aggregate, were recorded last week in Derby, Brighton, and Nottingham; and the highest in Preston, Sunderland, Norwich, and Cardiff. The greatest mortality from whooping-cough occurred in Bradford and Norwich; from measles in Sunderland and Cardiff; from scarlet fever in Newcastle-upon-Tyne and Halifax; and from "fever" in Preston and Norwich. The 35 deaths from diphtheria in the twenty-eight towns included 15 in London, 4 in Liverpool, 2 in Nottingham, 2 in Bradford, and 2 in Cardiff. Small-pox caused 60 deaths in London and its outer ring of suburban districts, and 2 in Liverpool. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which had been 1009 and 1092 on the preceding two Saturdays, further rose to 1147 at the end of last week; the admissions, which had been 216 and 287 in the previous two weeks, were 263 last week. The Highgate Small-pox Hospital contained 97 patients on Saturday last, 22 having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had been 609, 552, and 513 in the preceding three weeks, rose again to 556 last week, and were 16 above the corrected weekly average. The causes of 105, or 2·4 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Leicester, Derby, Norwich, and Plymouth. The largest proportions of uncertified deaths were registered in Oldham, Sheffield, and Huddersfield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had steadily declined from 30·7 to 28·5 per 1000 in the preceding four weeks, rose again to 30·2 in the week ending the 31st ult., and exceeded by no less than 5·7 the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 21·4 and 22·0 in Edinburgh and Leith, to 33·7 in Glasgow, 34·9 in Perth, and 41·9 in Dundee. The 738 deaths in the eight towns included 28 which were referred to whooping-cough, 23 to measles, 20 to diarrhœa, 11 to scarlet fever, 9 to "fever" (typhus, enteric, or simple), 7 to diphtheria, and not one to small-pox; in all, 98 deaths resulted from these principal zymotic diseases, against 83 and 86 in the preceding two weeks. These 98 deaths were equal to an annual rate of 4·0 per 1000, which was 1·7 above the mean rate from the same diseases in the twenty-eight English towns. The 28 deaths from whooping-cough showed a further slight decline from the numbers in recent weeks, and included 15 in Glasgow, 3 in Edinburgh, and 3 in Leith. The 23 fatal cases of measles were fewer by 3 than the number in the previous week; 12 occurred in Glasgow and 10 in Dundee. The 20 deaths attributed to diarrhœa showed an increase upon recent weekly numbers, and were 8 above the number in the corresponding week of last year. They included 7 in Glasgow and 5 in Dundee. The fatal cases of scarlet fever and of diphtheria showed an increase; 7 of scarlet fever and 5 of diphtheria were returned in Glasgow. The 9 deaths referred to "fever," of which 5 occurred in

Glasgow, corresponded with the number in the previous week. The deaths attributed to acute diseases of the respiratory organs in the eight towns, which had ranged from 203 to 196 in the preceding four weeks, rose to 214 last week, and exceeded by no fewer than 123 the number returned in the corresponding week of last year. The causes of 86, or nearly 12 per cent., of the deaths in the eight Scotch towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 31·0 and 31·9 per 1000 in the preceding two weeks, further rose to 35·5 in the week ending the 31st ult. During the first four weeks of the current quarter the death-rate in the city averaged 32·4 per 1000, whereas the mean rate during the same period did not exceed 24·0 in London and 23·9 in Edinburgh. The 240 deaths in Dublin last week showed a further increase of 24 upon the high numbers in recent weeks; they included 22 which were referred to the principal zymotic diseases, against 23 in each of the previous two weeks. Of these 22 deaths, 9 resulted from fever, 5 from whooping-cough, 3 from measles, 3 from scarlet fever, 2 from diarrhœa, and not one either from small-pox or diphtheria. These deaths were equal to an annual rate of 3·3 per 1000, the rate from the same diseases last week being equal to 2·1 in London and 1·9 in Edinburgh. The 9 deaths referred to "fever" exceeded the number returned in any recent week, and the 5 from whooping-cough also showed an increase; the fatal cases of scarlet fever, measles, and diarrhœa had declined. Two inquest cases and 2 deaths from violence were registered in the city; and 79, or more than a third, of the deaths were recorded in public institutions. The deaths both of infants and elderly persons showed a considerable increase last week. The causes of 20, or more than 8 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

THE post of Principal Medical Officer, South-Eastern District, which has been vacant since the retirement on the 15th July last of Deputy Surgeon-General W. Stewart, has been temporarily filled by Brigade Surgeon George Langford Hinde; Deputy Surgeon-General R. Wolseley, Sanitary Officer, Aldershot Division, has been appointed Principal Medical Officer, North British District, Edinburgh; Deputy Surgeon-General W. Skeen has been appointed Principal Medical Officer to the troops stationed in the Cork District.

WAR OFFICE.—Army Medical Staff: Surgeon John Buxton, M.B., half-pay, has retired from the Service, receiving a gratuity; Surgeon William Maunsell-Collins, M.D., retires from the Service, receiving a gratuity; Brigade Surgeon W. C. Boyd has been granted retired pay, with the honorary rank of Deputy Surgeon-General; Surgeon-Major R. W. Forsayeth has been placed on retired pay, with the honorary rank of Brigade-Surgeon; Surgeon-Major Robert Hyde has retired from the Service on retired pay, with the honorary rank of Brigade Surgeon.

INDIA OFFICE.—The Queen has approved of the transfer to the half-pay list of Surgeon-Major Theophilus Bolton Wright Plunkett Johnston, of the Bombay Medical Establishment.

ADMIRALTY.—The following appointments have been made:—Staff Surgeon James Dear Smith, M.D., to be Fleet Surgeon in Her Majesty's Fleet; Deputy Inspector-General Michael W. Cowan, M.D., to Bermuda Hospital; Surgeon Samuel Johnson, M.B., to the *Ranger;* Surgeon Francis G. Wright, to the *Asia;* Surgeon W. Eames, to the *Grappler;* Surgeon John L. Aherne, B.A., to the *Sultan.*

ARTILLERY VOLUNTEERS.—2nd East Riding of Yorkshire: Lieutenant Frederick Richard Chapman, M.B., is appointed Acting Surgeon.

ENGINEER VOLUNTEERS.—1st Gloucestershire: Surgeon George Adams resigns his commission; but is permitted to retain his rank, and to continue to wear the uniform of the corps on his retirement.

RIFLE VOLUNTEERS.—1st Cambridgeshire: Acting Surgeon George Edward Wherry, M.B., resigns his appointment.

THE HOSPITALS ASSOCIATION.—The first annual meeting of this Association is to be held on March 11th, when Sir Andrew Clark, Bart., M.D., will preside.

Correspondence.

"Audi alteram partem."

HARVEY'S MANUSCRIPT LECTURES.

To the Editor of THE LANCET.

SIR,—The MS. of the original lectures at the Royal College of Physicians by William Harvey, including his earliest observations on the heart and circulation, and delivered by him in and after 1616, were rediscovered in the British Museum in 1877. I gave a description of the little book, and exhibited an autotype copy of one page in my Harveian oration at the College in 1877. I then suggested that it would redound to the honour of the present generation, and be an advantage to the history of medicine, if the whole of the lectures could be published in autotype, accompanied by an intelligible transcript. The handwriting is so crabbed, and there are so many abbreviations, that no one but an expert could succeed in understanding them. Without the valuable aid of Mr. Bond, now the chief of the British Museum, I should have failed in my attempts to understand much, if anything, of the lectures. By dint of severe labour Mr. Bond succeeded in interpreting one of the lectures, and has now been good enough to make me acquainted with a gentleman who will undertake to transcribe the whole of the lectures. My inquiries lead me to believe that no publisher could be found to undertake the risk of publication in the form proposed, unless guaranteed a certain amount of professional support. On the other hand, I calculate that if from two to three hundred gentlemen would engage to each take a copy at a price not exceeding two guineas, the work might be safely proceeded with. Autotyping is a much more expensive process than ordinary printing, and the honorarium to the transcriber would necessarily add considerably to the cost.

May I ask your permission to submit the question to my professional brethren through your journal whether they will aid in this labour of love of, and admiration for, our great prototype of the scientific physician? I am permitted to state that the Presidents of the Royal Colleges of Physicians and Surgeons warmly support the undertaking.

I am, Sir, your faithful servant,

EDWARD H. SIEVEKING, M.D.

17, Manchester-square, W., Feb. 2nd, 1885.

P.S. Any communications on the subject may be addressed to me, or to Messrs. Churchill, 11, New Burlington-street, W.

CONGENITAL DISLOCATIONS OF THE HIP.

To the Editor of THE LANCET.

SIR,—In his inaugural address,[1] Professor Bennett has alluded to some work of mine in connexion with congenital dislocations, and thinks he has proved that any theory I have advocated "falls to the ground." Contrary to the usual course, Dr. Bennett has in his address discussed a single topic, and has selected this one "by the accident of obtaining a recent specimen of congenital dislocation of the hip." This was taken from a child, six years of age, in whom there was "no evidence of arrest of development as the cause of dislocation." "In discussing the subject his object was to revive the knowledge of what had conferred great honour on the profession of this city (Dublin), and to point out that the pathological facts recorded by his predecessors in the Surgical Society had been too much ignored, notably Hutton's demonstration of the true position of the head of the femur."

In the year 1835, Dr. Hutton[2] brought the case alluded to, of John N——, aged thirty-one, who "had always been an idiot," before the Medical Section of the British Association in Dublin. There was discovered "a remarkable deficiency of development in the right hemisphere of the brain; a great part of the right hemisphere was deficient, and a serous cyst, filled with limpid fluid, five inches in length and between two and three in its transverse diameter, occupied the hiatus." Moreover, there was dislocation of the left hip, together with atrophy of the limb, and contraction and atrophy of the left upper extremity, with sub-

[1] The Dublin Journal of Medical Science, January, 1885.
[2] The Dublin Journal of Medical and Chemical Science, vol. viii., 1836.

luxation of the radius and deformity of this bone and of the bones of the carpus. The whole limb was atrophied, and the forearm was permanently flexed on the arm. These are the cases on which Dr. Bennett founds his argument. He reviews, cursorily, the theories of Dupuytren, and those of Ammon, Cruveilhier, Chelius, Stromeyer, and South, and does not agree with any of them. He writes thus, "The last theory I purpose mentioning is one which has been strongly supported by Mr. South—namely, that the deformity was due to abnormal delivery, to breech presentation of the fœtus, and to force during delivery by the hook or other means applied upon the flexure of the thigh." And he thinks that "the most important theory is that of Guérin—namely, that during fœtal existence some irregularity of nerve action occurred, and the muscles in particular groups became affected for the time spasmodically. Whatever the change was, whether spasmodic action of muscle or simple disorganisation of muscle of any kind, it was followed by retraction of the muscle." And upon this he says, "I assume as the first point that congenital dislocation of the hip, of the shoulder, and of the elbow, and congenital club-foot are all deformities of the same class." And again, "The congenital dislocation of the hip is a single dislocation, varying in degree but not in kind."

Now, I have endeavoured elsewhere to show that congenital dislocations may be divided into two classes—viz., those connected with some abnormality or monstrosity (and these are for the most part subluxations), and dislocation of the head of the femur upwards and outwards, which is not uncommon, and which occurs without other abnormality. I have had forty of these cases under my care, of which thirty-one were double and nine were single dislocations; and, so far as I have been able to learn, with one exception only, all occurred in preternatural labours. The other was the result of violence immediately after birth.

After I had given some attention to this subject, I saw three cases with Dr. Tyler Smith. They all had the peculiar lameness of congenital dislocation, and he told me that all occurred in breech presentations, and that he had assisted the birth with the finger or with the hook in the flexure of the thigh. In these and in other similar cases he had heard a click after making traction, but he did not explain it to himself. In such cases I have never seen anything which would denote spasm; nor in such cases have I met with talipes or other distortion except in one instance. In this case a boy had congenital dislocation of the left femur and double varus; one of his sisters had double dislocation, and the other had dislocation of the right femur. Neither of the sisters had any other abnormality. The mother's pelvis was deformed, and she died in giving birth to a fourth child.

It will be remarked that Dr. Bennett says of his case, a girl six years of age, that there was "no evidence of arrest of development as the cause of dislocation." And he adds that he "was struck with the destruction of the fibres of the gluteus maximus muscle—indeed, they had almost disappeared in places." Now, because there was no arrest of development, dislocation must have occurred through violence, and the violence must have been such as to rupture the fibres of the gluteus maximus. Dr. Bennett thinks that there is no proof of external violence, but that displacement is caused by intra-uterine spasm. Did anyone ever hear of such intra-uterine spasm as to rupture the gluteus maximus? Even Guérin never proposed such a theory. That has been left entirely for Dr. Bennett, and I doubt if anyone will contest the honour of the discovery with him.

With regard to the second case (Dr. Hutton's), it is obvious that it does not enter into the category. I know the preparation, and believe it to be a case of hemiplegia, with subsequent displacement. But whether it is so or not, it is scarcely such a case as should be selected to show "the true position of the head of the femur" in congenital dislocation—a hemiplegic idiot of thirty-one years.

Dr. Bennett thinks that the operation which I proposed, and have frequently done, is "a possibility," but "rather a large order." To anyone who is in the habit of operating, it is simple enough; it may seem terrible to others. The last operation of this kind that I performed was done nine weeks ago. The head of the bone is now well fixed in the acetabulum, and the child can raise the limb easily from the couch. Also, she can stand without apparatus, and can walk. I should be delighted to show this case to Dr. Bennett. It is said that one fact is worth a hatful of theory. I hope I may persuade Professor Bennett that my facts are worth more than his theory.

Yours obediently,

Grosvenor-street, Jan. 29th, 1885. B. E. BRODHURST.

HEMIANÆSTHESIA FROM CONGENITAL BRAIN DISEASE.

To the Editor of THE LANCET.

SIR,—In an annotation which appears under the above title in your last issue with reference to a case which I brought before the last meeting of the Clinical Society, it is stated that the title of my paper could only be justified on the *lucus a non lucendo* principle; and that no evidence had been forthcoming that the affection was congenital. As this statement is not in consonance with the facts of the case, I must ask you to allow me to mention that I expressly stated at the meeting, in reply to a question from Dr. Adeney, that a full history of the case had been given to me by the father of the girl, a very intelligent man. It was to the effect that the primary cause of the child's illness had by her medical attendant been pronounced to be (I am now quoting the *ipsissima verba* from a letter of the girl's father to me, dated April 24th, 1884) "a paralytic seizure at or immediately after birth, *which has affected her left side ever since*, and is more noticeable in her left arm than in her left leg." This seizure was also considered to be the cause of the epileptic fits, from which she had suffered at intervals ever since birth. When she was about twelve months old she was taken to Dr. Russell Reynolds and Sir James Paget, and the former of these gentlemen expressed the opinion that the child could not be expected to talk until it was six or seven years of age.

I trust that these details will satisfy you and the writer of the paragraph in question that the case was really one of congenital brain disease, and not, as he avers, one of functional or hysterical hemianæsthesia. If I had thought it to be one of the latter kind I should not have brought the case before the Society, as I consider that subject to be thoroughly threshed out. My case was, however, one of an entirely different nature, and also a most unusual and exceptional one. For this reason there may naturally be differences of opinion with regard to the localisation of the lesion, and the remarks of Dr. Angel Money were very much to the point in this respect; but that there was really a cerebral lesion, produced at or immediately after birth, cannot for an instant be doubtful. Moreover, if the affection had been hysterical, there would most probably have been the usual phenomena of transfer after the application of electricity, which was not the case.

I am, Sir, your obedient servant,

Harley-street, W., Feb. 1st, 1885. JULIUS ALTHAUS, M.D.

*** Our difficulty in adopting Dr. Althaus' view presents itself in the following light:—If the morbid symptoms which lasted for eleven years without variation depended on a coarse lesion of the brain, and if the case were cured, then it is clear that electricity can get rid of the effects of very chronic organic brain disease—a position which we prefer not to accept until substantiated by post-mortem experience.—ED. L.

THE UNIVERSITY OF LONDON.

To the Editor of THE LANCET.

SIR,—At a recent meeting of Convocation I see that Dr. Curnow moved, and Mr. Christie seconded, "The desirability of holding the preliminary scientific examination twice a year." Could not a proposition somewhat similar in character, but more comprehensive, be carried applying in like manner to all the examinations up to and including those for the degree of Bachelor in all the faculties? This would be a great boon to medical students whose degrees are not ornamental titles, but essential to the practice of their profession. Another point or two also may be considered with advantage to them:—1. Whether the four years of medical study required for the M.B. may not be counted from any time after having been registered as a student of medicine, before or after matriculation, and not, as now, divided into two fixed periods between each examination. 2. The desirability of dividing the subjects of some of the examinations into parts, or if the candidate pass in a certain number of them—say a half—let such subjects be allowed him at any subsequent examination, he not being then permitted to compete for honours. The examinations are so numerous and so severe that some means might reasonably be carried out

to hold them more than once a year, and also to remove those arbitrary periods of study between each examination. If the university should still continue to act as an examining board only, might not something be done to improve the position of those who matriculate by giving them some designation, such as "L.A."—Licentiate in Arts? This examination is acknowledged to be the most severe of its kind, and is also the Arts examination for degrees in Medicine, Law, and Science. If such a designation were granted, no doubt a very much larger number of candidates would come forward than at present. Many of those who pass it never intend going further, and take the examination merely as evidence of a good general education, but find that, without some such designation, it is of little use to them in after-life.

I am, Sir, yours, &c.,

Jan. 11th, 1885. M.D.

THE NEW SCOTTISH CONJOINT EXAMINATIONS.

To the Editor of THE LANCET.

SIR,—As your columns are always open to correspondents who aim at exposing abuses of medical examinations, I would like to make a few remarks on the new Scottish Conjoint Scheme of Examinations, from which great things were hoped for by the friends of the Scottish corporations.

At the first professional examination just concluded, many of the candidates, who were allowed to pass by the so-called just and conscientious examiners, practically knew nothing of their work, and would not have been allowed to pass by any licensing board in England or Ireland. Four candidates I know of actually were advised not to think of presenting themselves, as there was not the slightest chance of their passing, yet every one of these four men entered, and *passed*. It is a well-known fact that in the written part of the examinations wholesale "cribbing" is practised, the candidates being allowed to sit where they like, and they take the advantage of arranging beforehand beside whom they are to sit. These things must be known to the examiners, and yet not the slightest effort is made to prevent their occurrence. The second and final examinations are certainly conducted with ordinary severity, so far at least as the oral and practical parts are concerned; but even in these important examinations the written part of the test is merely a farce, owing to the help given by one candidate to another. It is indeed time that the system of visiting examinations, particularly in Edinburgh (it is not unnecessary even at the university), should be regularly and strictly carried out.

I am, Sir, yours, &c.,

Edinburgh, Jan. 19th, 1885. M.D., F.R.C.S. Edin.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

THE WEATHER AND MORTALITY IN THE NORTH.

SITUATED as we are in the narrowest part of England, and between two seas, we are well accustomed to change of weather; but the present winter has been so far one of the most changeable on record, and is noteworthy, if not for its severity, at least for its variableness. There has been no great amount of disease, and we cannot say that the aggregate mortality has been increased; still there has been some influence very deadly to aged persons within the last few weeks, and our newspaper obituary has been remarkable for the great ages recorded. This mortality in the aged has been observed to be coincident with thermometric changes, sometimes as much as ten and fifteen degrees between two days.

THE HELM WIND.

Attention has been called in the press to the remarkable manifestations of the phenomenon known as the helm wind, which was observed in Carlisle and its neighbourhood on the 16th and 17th ult. It was noticed as a dark-coloured cloud resting like a cap upon a portion of the Pennine range of mountains between Crossfell and the Cheglin Fells, the broken fragments of clouds being driven with great speed from the east; the rustling noise of the wind, which resembled the roaring of a heavy sea when it breaks upon a rocky shore, and the lifting force and whirling sensation peculiar to this wind, being very marked. This remarkable wind is confined to this district of England, and its lifting force is such as to sometimes overturn vehicles and animals caught in its course, which seldom extends beyond seven miles from where it originates. Sometimes there is a second cloud, called the "helm burr," further back and higher than the ordinary beautiful bar, but it was not observed on the late occasion. The Royal Meteorological Society is now obtaining facts, and the results of observations in the various districts where the "helm" blows, which cannot fail to prove of interest when published.

NEWCASTLE LYING-IN HOSPITAL.

The annual meeting of governors was held last week, Dr. Gibson of our city occupied the chair. The report of this useful charity showed that 359 cases had been attended during the past year, and considering the prevalent distress, and that the cases would be among the extreme poor, it is satisfactory to hear that throughout the year there had not been a single fatality.

NEWCASTLE THROAT AND EAR HOSPITAL.

The annual meeting of this charity was held on Monday last, the Bishop of Hexham and Newcastle presiding. The report showed that about 1600 patients had been admitted to the benefits of the institution during the year, being an increase of 400 over the previous year; 673 had been treated gratuitously, while the important amount of £208 had been contributed by voluntary offerings of patients. The institution is quite free from debt, but its increasing popularity renders it necessary for the governors to take steps for its early enlargement.

THE NEWCASTLE INFIRMARY.

The question of the enlargement of the infirmary on its present site or the erection of a building on a new site may now be regarded as settled by the compromise unanimously agreed upon at the late court of governors, in the following terms:—"That the question of the extension of the present infirmary by the erection of a permanent wing be abandoned, and that a temporary wooden building be erected in the garden, at a cost of about £2000;" and, "It being apparent that the time has arrived when the Newcastle-upon-Tyne Infirmary should be removed to a more salubrious situation, the special committee be empowered to negotiate for a new site suitable for the erection of a hospital capable of accommodating 300 or more patients, to be designed in accordance with the latest and most approved principles of hospital accommodation, obtained by open and public competition; to prepare the necessary instructions for designs and plans, and to take steps to obtain the funds necessary for the undertaking." To the speedy and unanimous action of the medical staff the public are indebted for this satisfactory aspect of the question; and yet, to an outsider, it does appear a pity that £2000 and more should have to be spent on a temporary wooden building.

TYPHOID FEVER AT WOLSINGHAM.

A very serious outbreak of typhoid fever has taken place at Wolsingham, in the adjoining county of Durham. Wolsingham is a manufacturing and mining town of about 7000 population. The staple trade is iron and steel, and it is principally among the workers that the epidemic prevails. Over sixty cases are reported so far.

Newcastle-on-Tyne, Feb. 4th.

IRELAND.

(From our own Correspondent.)

BELFAST ROYAL HOSPITAL.

A SPECIAL MEETING of the Corporation was held last week for the purpose of considering the resolution upon religious registration adopted by the Board of Management on the 10th ult. The following was the resolution which the meeting was convened to consider: "That it be the duty of the house-surgeons and physicians to ask the following question of any patient entering this hospital, when in a condition to give an answer—'Do you wish to state your religious denomination?' If the patient expresses such a wish, the surgeon or physician shall enter the name, address, and religious denomination in a book kept for the purpose, to which all clergymen shall have access." After a very

stormy discussion, the following amendment was adopted: "That, considering the absolutely unsectarian character of the Royal Hospital, which has existed for nearly one hundred years, ministered to and supported by all parties and classes in the community, and that the system as at present administered has proved satisfactory to the Board of Management, the medical staff, and the visiting clergy, we decline to make any change in the present management."

BRITISH MEDICAL ASSOCIATION.

The annual meeting of the Dublin Branch took place on the 29th ult. The Council, in their report, referred to the great block that exists in the senior ranks of the Army Medical Department, and appointed last year a subcommittee to draw up a report on the subject. After the Council had received this, they learned that the authorities were then engaged in the consideration of impending changes in the department, and therefore deemed it opportune at such a time to take further action upon it. The Council regretted to say that since the report was received the matters referred to in it had not improved. The meeting passed a vote of thanks to Mr. Edward Hamilton for the manner in which he had performed the office of president during the past year; and the incoming President (Dr. Atthill) delivered his inaugural address on the subject of medical reform.

Dr. Barron has been presented by the students of the Belfast Royal Hospital with an address and a collection of surgical instruments, on the occasion of his severing his connexion as visiting surgeon to the hospital.

Compared with the corresponding quarter of 1883, the returns of pauperism furnished by the Local Government Board for the last December quarter show a decrease of 651 in the average number of workhouse inmates throughout Ireland on Saturdays during the quarter, and a decrease of 1187 in the average number of persons in receipt of out-door relief.

Dublin, Feb. 3rd.

BELFAST.

(From our own Correspondent.)

THE BELFAST HOSPITAL FOR SICK CHILDREN.

FROM the reports read at the twelfth annual meeting of this most popular charity we gather that during the past year there were 342 intern patients, while during the same period there were 8509 out-patients, a number which exceeds that of any previous year. The senior students attending Queen's College have, as heretofore, attended the practice of the hospital. In accordance with a rule by which a physician and surgeon retire alternately, an election was held on January 8th, on which occasion Dr. Byers was unanimously re-elected for four years as honorary attending physician. Dr. Nelson has been appointed honorary oculist. More than one hundred ladies of the committee and other friends have guaranteed to raise each £5 or more, by which a sum of at least £500 will be added to the capital of the hospital before June 1st next. This plan, it was thought, would be better than raising the money by a bazaar. Already nineteen ladies have handed in subscriptions amounting to an average of £7 each.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST.

The second annual meeting of this institution was held on January 25th. During the past year 715 new cases have been under treatment, the total number of visits paid by these patients amounting to 3611. The financial statement showed that there was a balance in the treasurer's hands of £10 15*s.* 5*d.*, and the receipts from "pay-patients" during the last year have been £37 1*s.* It is to be regretted that the funds of the institution do not as yet warrant such an increase of expenditure as would provide a few beds for cases of severe illness.

THE SAMARITAN HOSPITAL.

The annual meeting of the friends and supporters of this hospital, which is specially devoted to the "medical and surgical relief of women affected with diseases peculiar to the sex," was held on January 29th. There were 1100 patients treated during the year 1884. Of these 1016 were treated in the extern department and 84 in the wards. The number of visits made by the extern patients was 5798. The patients have contributed £250 to the funds during the year—a very interesting fact.

ULSTER EYE, EAR, AND THROAT HOSPITAL.

During the year ending December 31st last 1961 cases were under treatment; of these 100 had continued in attendance from the previous year, and 1861 were new cases. There were 223 intern patients. The committee have for several years advocated the partially self-supporting system of hospital management. Of the extern patients 1103 paid an entrance fee of one shilling, and 635 were treated free. Of the ordinary intern patients 66 were free, whilst 112 were paid for. Private wards were let to 45 private patients. During the present year senior students of the Belfast Medical School have been permitted by the acting surgeon, with the approval of the committee, to be present at operations. During the year 120 important eye operations, including 60 cataract extractions, 22 operations for squint, and 13 cases of removal of the eyeball, were performed. Three hundred and fifty-eight other operations, including the ear and throat, and minor operations on the eye, were also performed. It has been decided to appeal to the public for funds to carry out the plan of extension of the hospital as recommended by the surgeon, Dr. McKeown. He advised the addition of two day-rooms, two small wards for ear and throat cases, two small wards for contagious cases, a dormitory for an additional nurse, a dark room for oxy-hydrogen light, and open-air exercise ground.

PARIS.

(From our Paris Correspondent.)

PROSECUTION OF MEDICAL MEN IN PARIS.

A RATHER strange prosecution against four medical men was brought before the Correctional police last week by a M. Bouyer, who charged them with malpraxis, which, he stated, resulted in his being disabled for life, and claimed 20,000 francs damages. The charge was founded on the following circumstances:—The plaintiff, who was an "officier de santé," although he never practised, and edited a financial paper, assuming the title of "Dr.," applied to Dr. Piogey for advice for a wound in the hand, accidentally caused by a rusty nail about fifteen months ago. Phlegmonous inflammation having set in and gangrene threatening, Professor Trélat and Dr. Delens, two eminent surgeons, were called in consultation. These gentlemen considered it necessary to make free incision and to apply drainage-tubes, to save not only the patient's arm, but even his life, which was much endangered, as he was also diabetic. The doctors were, moreover, accused of having removed him, contrary to his will, and whilst in a state of delirium, to a "maison de santé," although it was done for his own personal advantage, his own room being in a most insanitary condition. At the "maison de santé" he received every care and attention, and Dr. Piogey, under the impression that the patient was a professional brother, placed his own nephew, who bears the same name, and who is also a physician, in constant attendance on him. The other three doctors paid him regular visits as long as necessary, and on the assumption that the patient was a *confrère*, did not make any charge for their professional services. On his recovery the patient left the "maison de santé," and his first act was to prosecute his benefactors on the charge mentioned above. A more flagrant example of ingratitude can scarcely have been recorded in medical history, and the judges, concurring with this view of the case, rebuked him, and not only did not allow him damages, but condemned him to pay 12,000 francs, to be divided equally among the four doctors.

PRIZES AT THE FACULTY AND ACADEMY OF MEDICINE.

The Faculty of Medicine of Paris has awarded the prix Châteauvillars to Dr. Constantin Paul for his work entitled "The Diagnosis and Treatment of Diseases of the Heart." The Academy of Medicine has divided that portion destined for prizes of the Morbinne legacy among the following gentlemen: Dr. A. J. Martin, 4000 francs, for his work on the "Civil Sanitary Administration in Foreign Parts and in France;" Drs. Straus and Roux, 2000 francs each, for their cholera researches at Toulon; Dr. Van Morris, of Dunkirk, 2000 francs, and to Dr. Amat, military surgeon, 500 francs, for their memoirs on the influence of sea-bathing in the treatment of scrofula in children.

FEMALE STUDENTS AS INTERNES.

The question of the admissibility or the inadmissibility of female medical students to the "internat" of hospitals has just been discussed at the Municipal Council of Paris; and although Dr. Peyron, the Director of Public Assistance, and other members pointed out in strong terms the inconvenience that would arise from the lady students having to eat and sleep in the same room with the male students, their admissibility has been voted by 48 against 25. A compromise, however, has been proposed to the effect that a separate room shall be allotted to the lady students.

UPROAR AT THE SCHOOL OF MEDICINE.

Some disturbance took place last week at the School of Medicine during Professor Robin's lecture, some of the students having resorted to the by no means commendable practice of uproarious interruptions during the discourse crying out "Your resignation!" "Go to the Senate." Professor Robin has never been very popular among the Paris medical students, as he has always been rather severe at the examinations. But this is not the only reason. I believe they simply wish to make the berth which he has occupied for more than thirty years "too hot" for him, so that he may be induced to leave it and make room for someone more in favour. Meanwhile Professor Robin's course of lectures on histology has been suspended until further orders.

Paris, Feb. 4th.

Obituary.

CHARLES CULLEDGE BALDING, M.R.C.S., L.S.A.

A LITTLE more than a year ago we noticed the fact that Mr. C. C. Balding had been compelled to retire from practice at Shefford, owing to continued ill-health; and the occasion was marked by the presentation to him of a complimentary address and testimonial, expressive of the high esteem in which he was held by those among whom he had practised since 1857. The illness from which he suffered terminated fatally on the 24th ult. It was locomotor ataxy, and for nine years he had continued to pursue his unselfish labour amongst all his patients, rich and poor, whilst suffering often from the increasing and agonising pains of that formidable disease. He deserves to be remembered for this heroic struggle against his own physical pain whilst engaged in relieving the sufferings of others. Mr. Balding was the second son of the late Mr. James Balding, of Barkway, who died at an advanced age in September, 1883. Two of his brothers, Mr. D. B. Balding of Royston and Dr. Mortimer Balding of St. Albans, are well known to the profession. All three brothers received their medical education at the Middlesex Hospital. Soon after leaving the hospital Mr. C. C. Balding in the early part of the Russian war accepted an appointment on the Army Medical Staff for service in the Crimea. He was with several personal friends detailed for duty at Eupatoria, where, owing to the failure of the British Commissariat Department, they were subjected to great privations, which told seriously on the health of himself and of those who were quartered there with him. He afterwards served at Trebizond, where he remained until the end of the war. After his return home, in somewhat impaired health, he renewed his work at the Middlesex Hospital, and subsequently, in November, 1857, commenced practice at Shefford, by succeeding to that of Mr. J. M. Layman, whose daughter Ellen he afterwards married. Here he soon gained the confidence of a wide circle, and his professional work became laborious.

The funeral took place at Campton, on Thursday, Jan. 29th. The coffin was of plain oak, and upon it were carried the Crimean medals and sword of the deceased, and numerous wreaths sent by sympathising friends. He was followed to the grave by his three sons and four brothers, and also by Mr. C. Layman (brother-in-law), and the funeral was attended by all the members of the medical profession in the town and neighbourhood, as well as by most of the principal inhabitants. The deceased leaves a widow, and family of three sons and two daughters.

We believe that an endeavour will be made to procure for one of the sons the privileges of education at Epsom Medical Benevolent College, and we cordially commend to the notice of the governors the son of so honourable and heroic a member of our profession.

WILLIAM BRAITHWAITE, M.D.

DR. WILLIAM BRAITHWAITE of Leeds, whose death occurred on the 31st ult., was born in 1807, and was consequently in his seventy-eighth year. After serving an apprenticeship to the late Mr. Thomas Teale, and afterwards to Mr. T. Pridgin Teale, Dr. Braithwaite pursued his professional studies at St. George's Hospital. He became a Licentiate of the Society of Apothecaries in 1828, a Member of the Royal College of Surgeons in 1829, and in 1860 he received the degree of M.D. from the University of St. Andrews. In 1830 he commenced practice in Leeds on his own account, and filled the posts of honorary surgeon to the Eye and Ear Infirmary and lecturer at the Leeds School of Medicine on the diseases of women. In 1840 he commenced the publication of the "Retrospect of Medicine," a work which has proved of much value to, and gained great approval from, the members of the medical profession. Dr. Braithwaite was the oldest medical practitioner in Leeds, and, on account of his professional ability and his sympathetic and kindly disposition, was held in high esteem by all with whom he came in contact.

HENRY A. MARTIN, M.D. BOSTON, MASS.

THIS well-known surgeon died on Dec. 7th, 1884, aged sixty years. He graduated at the Harvard Medical School in 1845, and commenced practice shortly afterwards. On the breaking out of the war in 1862 he was appointed staff surgeon, and served in that capacity at Fort Monroe. Subsequently he became medical director of the department of South-Eastern Missouri, of Norfolk, Portsmouth, and Newbern; and then, in the Army of the Potomac, surgeon-in-chief of the first division of the Second Army Corps. On his resignation he received the brevet rank of Lieutenant-Colonel for "gallant and meritorious services." In 1870 Dr. Martin introduced the Beaugency virus into America: and in 1877 he brought before the notice of the profession the pure rubber bandage, the use of which he proposed in the treatment of ulcers of the leg.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—The following gentlemen were admitted Members of the College on the 29th ult.:—

Dakin, William Radford, M.D. Lond., Edith-road.
Foxwell, William A., M.B. Camb., General Hospital, Birmingham.
Handford, Henry, M.D. Edin., Nottingham.
Lewers, Arthur Hamilton Nicholson, M.B. Lond., Gower-street.
McDonagh, John Michael, M.D. Brussels, Beaufort-street.
Pasteur, William, M.D. Lond., Queen-street, Mayfair.

On the same day the following candidates were admitted Licentiates:—

Adams, Gofton Gee, Oakfield-park, Clifton, Bristol.
Annacker, Ernest, Oxford-street, Manchester.
Bower, Edward Ignatius, Acton-street.
Bowie, Robert Forbes, Huntley-street.
Bury, Herbert Taylor, Granby-street.
Canfield, Ralph Metcalf, M.D. Vermont, Amwell-street.
Cox, Robert Hippisley, Mount-street.
De'Ath, George Hanby, Guy's Hospital.
De Montbrun, Domingo Antonio, Osnaburgh-street.
Dingley, Arthur William, Camden-road.
Downes, Howard, St. Mary's-road, Canonbury.
Fetherstonhaugh, Robert Trevor, Park-road, West Dulwich.
Fisher, Henry Holdrich, Wilmington-square.
Gilbertson, James Henry, Hertford.
Gordon, Frederick William, Brynarlais, Llandidrod Wells.
Gubb, Alfred Samuel, French Hospital, Leicester-square.
Hacking, John Herbert, Old Trafford, Manchester.
Hall, William Hamilton, Claremont-square.
Henry, William George, M.D. McGill, Torrington-square.
Huntington, William, Amberley-street, Liverpool.
Jones, John Arnallt, Tir Caradoc, Talbach.
Josling, Charles Langford, Sidcup.
Kebbell, Charles, Sussex County Hospital, Brighton.
Lake, Richard, Bessborough-gardens.
Laurie, Caspar Robert, Buckhurst-hill.
McKillop, Alexander, M.D. Toronto, Nicholas-street.
Medley, Harold, Thomas Dupuis, Brondesbury Villas.
Messiter, Arthur Frederick, Willington, Burton-on Trent.
Mullis, George William, Penton-place.
Page, Alfred Matthew, St. John's-wood-terrace.
Parfitt, Edward Browne, Maxilla-gardens.
Pulling, Herbert John, Denbigh-street.
Ross, William Albert, Toronto, Canada.
Rugg, George Lewis, Stockwell Villa, Clapham-road.

Shackel, George Arthur, Erleigh Court, Reading.
Smith, Albert, Stockwell-green.
Spry, William, Upper Bedford-place.
Staddon, John Richard, Fentiman-road.
Stewart, George Eland, Coburg-road.
Strickland, Charles, Warwick-road.
Thorold, William Grant, Sussex-street, Pimlico.
Tratman, Frank, St. Peter's-road.
Turner, Frederick Senior, Avenue, Chiswick.
Washbourn, William, Granby-street.
West, Charles James, Buckingham Palace-road.
Williams, Reginald Muzio, Blackheath-hill.
Williams, Robert Richard, Ampton-place.
Winckler, William, University Hospital.

The following gentlemen passed the Primary Examination for the Licence on the 2nd inst.:

A. J. Adie, H. Armstrong, R. D. Barber, W. O. Barsham, H. C. Bartlett, W. Bett, E. G. Blaxland, B. M. Bond, H. B. Brackenbury, C. Christopherson, S. A. Clarke, R. G. Cookson, E. E. Dalton, E. P. Daniell, H. M. L. Dean, H. Debenham, R. B. Eccles, C. H. Evans, F. R. Farmer, M. J. Finucane, N. H. Forbes, F. T. Frost, W. R. Garrould, W. Green, H. E. Hackett, W. Harries, H. J. Hawthorn, E. J. Haynes, C. P. K. Hemming, W. H. Henshaw, C. T. Hudson, F. H. Hudson, J. Hutchinson, T. B. Jacobson, A. G. James, J. A. James, T. John, R. F. Jowers, C. N. Lovely, W. R. N. Maloney, F. G. S. G. Martin, F. R. Miller, E. Morris, W. H. Moyle, S. A. Mugford, G. W. Ord, A. E. Palmer, H. C. Parsons, A. E. Paul, G. Perrin, J. D. Price, W. T. Rayne, R. F. Reading, W. Roalfe-Cox, A. Roberts, P. Rose, H. W. Scratchley, P. I. Shopoff, H. Sieveking, C. S. Simpson, E. S. Smith, H. S. Smith, F. A. Warner, W. D. Wells, H. J. Wheeler, O. A. Wickham, S. Wigglesworth, V. Wigglesworth, C. Wisken, A. B. Woakes, R. W. Wright, T. N. Wright, J. H. Yolland, R. W. Young.

ROYAL COLLEGE OF SURGEONS OF ENGLAND. — The following gentlemen, having passed the required examination for the diploma, were admitted Members of the College at a meeting of the Court of Examiners on the 29th ult.:—

Dingley, Arthur William, L.R.C.P. Lond., Camden-road.
Messiter, Arthur Frederick, L.R.C.P. Lond., Burton-on-Trent.
Thorold, William Grant, L.R.C.P. Lond., Ilfracombe.
Lake, Richard, L.R.C.P. Lond., Bessborough-gardens.
Freeland, Freeland John, L.S.A., Torrington-square.
Wilding, James, L.S.A., Lambourne-road.
Maggs, William Adolphus, L.S.A., Hanover-square.
Thomas, Thomas William, L.S.A., Albert-street.
Shadwell, Harry Winstanley, L.S.A., Hammersmith.
McCabe, William Alexander Bowes, L.S.A., St. Heliers.
Williams, Edward Lloyd, L.R.C.P. Lond., Buckingham-gate.

Admitted on the 30th ult.:—

Bennett, James Robert Abrahall, L.S.A., Lydford, Devon.
Hall, William Hamilton, L.R.C.P. Lond., Lancing.
Guinness, Harry Gratton, L.S.A., Bow.
Staddon, John Richard, L.R.C.P. Lond., Ipswich.
Llewellyn, John, L.S.A., Mount-place.
Barron, Hunter Jackson, L.R.C.P. Lond., Endsleigh-street.
Edwards, Richard, Pontalgoal.
Oakley, William Donald, M.D. McGill, Ontario.
Mason, Francis John Goringe, Woolwich.
Nowell, Barnes, West Kensington.
Southern, Francis Gerald, L.S.A., Ludlow, Salop.
Coleman, William Edward, Albert-street.
Harris, Arthur Wellesley, L.S.A., Exmouth-street.
Kelson, William Henry, L.S.A., St. Peter's-street.
Soutter, James, L.S.A., Hull.
Hartzhorne, Bernard Frederic, L.S.A., Chiswick.
Davidson, Charles Robert, M.B. Durh., Lincoln.
Cropley, Alfred, L.S.A., Swaton, Lincolnshire.

Admitted on the 2nd inst.:—

Smith, Edward John, L.S.A., Brixton.
Rockwood, William Gabriel, M.D. Madrat, Ceylon.
Bencraft, Henry William Russell, Southampton.
Wright, Frank Marsh, L.S.A., Bottesford, Notts.
Stevenson, William Dymes, L.S.A., Kew Gardens.
Bateman, Frederick Augustus Newton, L.R.C.P. Lond., Pall-mall.
Jones, Herbert Charles Walter, L.S.A., Cheltenham.
Ritson, Robert, Maryport, Cumberland.

Admitted on the 3rd inst.:—

Barnett, Frank Septimus, L.S.A., Stoke Newington.
Huzzey, Reginald Lee, L.S.A., Ampthill, Beds.
Brooks, Samuel John, L.S.A., Tollington-park.
Sequeira, Henry James, L.S.A., Jewry-street.
Harcourt, Vincent Xymines, L.R.C.P. Lond., Eastbourne.
Nicholson, Henry Gilbert, L.S.A., Hereford.
Doudney, George Herbert, M.D. Durh., West Dulwich.
Munro, William John, M.B. Edin., Sydney, New South Wales.
Mathews, Frank Edward, L.S.A., Doughty-street.
Thompson, Walter Scott, George-street.

Admitted on the 4th inst.:—

Annacker, Ernest, L.R.C.P. Lond., Manchester.
Dixey, Frederick Augustus, M.B. Oxon., Oxford.
Jackson, Herbert Francis, Ballina.
Laurie, Caspar Robert, L.S.A., Bournemouth.
Wingrave, Vitruvius Harold Wyatt, L.S.A., Guildford-street.

Admitted on the 28th ult.:—

Sillick, James Henderson, Merrick-square.

Of 234 candidates who presented themselves for examination, 89 passed and obtained their diplomas; 45 passed in Surgery only and will receive their diplomas on passing in Medicine and Midwifery, or on obtaining a medical qualification; 17 were referred for 3 months, 76 for 6 months, 4 for 9 months, and 3 for one year.

COLLEGE OF PHYSICIANS IN IRELAND. — At the January examinations the following obtained the licences in Medicine and Midwifery of the College: —

MEDICINE.—W. Beatty, Francis Lindesay Carte, John Joseph Costello, John Alfred Laycock, James Griffiths Whittendale.
MIDWIFERY.—Louis Albert Frederick Bate, Francis Forster Brady, John J. Costello, Samuel Ebenezer Falconer, John Samuel Fenton, John Alfred Laycock, Alfred John Smith.

The undermentioned was admitted a Member:—
Robert Fitzmaurice.

APOTHECARIES' HALL. — The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on the 29th ult.: —

Barnard, Walter Burrows, Charing-cross Hospital.
Bennett, Deane, St. Mary's Hospital.
Bennett, James Robert Abrahall, University College.
Blomfield, George Wills, London Hospital.
Ensor, Edwin Thomas, London Hospital.
Guinness, Harry Grattan, London Hospital.
Haynes, Charles, Charing-cross Hospital.
Jones, Edward Francis, London Hospital.
Long, Frederick William Devereux, Charing-cross Hospital.
Noyes, Alexander, Wellesley Finch, Charing-cross Hospital.
Stephens, William John, King's College.
Weston, Joseph Theophilus, Bengal Medical College, Calcutta.

[After the name of Mr. Ernest Roach, in last week's list read, "Guy's and Queen's Hospitals, Birmingham."]

THE Queen has been pleased to announce to the father of the late Dr. Marshall, Her Majesty's Resident Physician, that she has granted him a yearly pension of £150 for life. Mr. Marshall resides at Crieff, Perthshire.

THE plans for a Paddington-green Park which Mr. Mark H. Judge submitted to the Paddington Vestry in 1883, are now being considered by the Metropolitan Public Garden, Boulevard, &c., Association.

MEDICAL MAGISTRATE. — Alex. W. Macfarlane, M.D., F.R.C.P. Edin., has been placed on the Commission of the Peace for the county of Ayr, on the recommendation of the Lord Lieutenant.

ON the recommendation of Mr. Gladstone, a grant of £100 from the Royal Bounty Fund has been made to Dr. George Gore, F.R.S., in recognition of his eminent services in original chemical research.

DEATH UNDER CHLOROFORM.—An inquest was held in Salford on the 29th ult. on the body of a boy who died in the Salford Hospital while under the influence of chloroform, given previous to the removal of a piece of necrosed bone from the leg. The jury returned a verdict of "Death by misadventure."

THE WELSH LIBEL CASE.—The action brought by Dr. Howell of St. Clears, medical officer to the Carmarthen Board of Guardians, claiming £10,000 from the Board for alleged wrongful dismissal and libel, has been dismissed with costs by the District Registrar of the High Court of Justice.

THE VENTNOR HOSPITAL. — The Royal National Hospital for Consumption and Diseases of the Chest, Ventnor, has just received the grant of a Royal Charter of Incorporation. The petition to the Queen was signed by the Duke of Albany, the then president, a short time before his decease. Lord Rosebery has since consented to act as his successor.

THE EPIDEMIC AT KIDDERMINSTER. — The official report of Dr. Parsons to the Local Government Board upon the enteric fever epidemic at Kidderminster was laid before the Town Council on the 4th inst. The sewers and house drains throughout the town are stated in the report to be seriously defective, and the question of contamination of the water-supply is discussed at some length. Dr. Parsons conclusion is that the cause of the epidemic cannot be be certainly assigned. He points out clearly the steps which ought to be taken as to improved water-supply, amendments in the sewerage, and other matters. The report of the engineer estimates the probable cost of the works required at £250,000.

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—The usual quarterly court of directors of the Society was held on Wednesday, January 14th, the President, Sir James Paget, in the chair. A sum of £1361 was voted to be distributed among the sixty-three widows

and eleven orphans in receipt of ordinary grants, and the three orphans receiving extraordinary relief from the Copeland Fund. The expenses of the quarter amounted to £61 8s. The acting treasurer announced a legacy of £100, duty free, from Dr. Nathaniel Rogers of Exmouth. Two new members were elected, the deaths of four reported, and the resignation of another accepted. Fresh applications for grants were received from three widows, for themselves and four children, and, on the report of the committee of visitors, assistance was given to all.

THE GERMAN HOSPITAL.—The report which was read at the recent annual general meeting of the subscribers to this institution stated that the number of in-patients during 1884 was 1822, of whom 353 were cases of accidents, most of them English; 45 were admitted into the sanitorium; 351 gained admission into the Convalescent Home at Dalston, and as many as 34 were sent to the Convalescent Hospital at Eastbourne. The number of out-patients last year was as follows:- At the Hospital Dispensary (including 200 cases of accidents treated as out-patients, three-fourths of them being English), 15,921; at the Eastern Dispensary of the institution, 3994; at the Western, 1760; dental cases, 1093; making a total (together with 1822 in-patients) of 24,590.

DEATH OF MR. GEORGE J. FORD.—It is with regret that we record the death, on the 3rd instant, at the Royal College of Surgeons of England, of Mr. George Jaques Ford, at the age of sixty-five, from Bright's disease. Born on Dec. 11th, 1819, at Balsham, Cambridgeshire, he entered the service of the College as hall porter in 1840, where during upwards of forty-four years he secured the esteem, trust, and indeed friendship of all the officers and servants. During his illness he was attended by Dr. Frederick J. Goodhart with unceasing care and kindness. The older Fellows and Members of the College will miss a well-known face on entering the College, and one which served as a connecting link between the past and the present. By his death the College loses an old and trustworthy servant. The funeral will take place at Kensal-green Cemetery to-day (Saturday), at 2.30 o'clock.

HUNTERIAN SOCIETY.—The annual meeting of this Society will be held on Wednesday, Feb. 11th, at 7.30 P.M.; after which, at 8 P.M., the oration will be delivered in the theatre of the London Institution by Dr. F. Charlewood Turner. The annual dinner will be held at the "Albion," Aldersgate-street, on Friday, Feb. 13th, at 6.30 P.M., Dr. Robert Fowler, President, in the chair. The following is the list of officers for the ensuing year:—President: Dr. Pye Smith. Vice-Presidents: Dr. Major Greenwood, Mr. W. C. Toulmin, Mr. William Clapton, Dr. Stephen Mackenzie. Treasurer: Dr. Fotherby. Trustees: Dr. Fotherby and Mr. De Berdt Hovell. Librarian: P. L. Burchell, M.B. Orator: Sir Andrew Clark. Secretaries: Mr. Charters Symonds and Dr. Charlewood Turner. Council: Drs. Carrington, Robert Fowler, E. G. Gilbert, J. Dundas Grant, W. Talbot King, John Millar; Messrs. G. Ernest Herman, F. M. Corner, Charles Davidson, T. R. Fendick, W. Rivington, R. G. Tatham.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

BERRINGER, Mr. J. J., has been appointed Public Analyst for the Borough of Penryn.

BROWNE, GEO. HENRY, L.F.P.S.Glas., L.R.C.P.Ed., L.A.H.Dub., has been appointed Public Vaccinator for the Llanelly District of the Crickhowell Union.

CARRINGTON, R. EDMUND, M.D.Lond., M.R.C.P.L., has been appointed an Assistant-Physician to Guy's Hospital.

CASSAL, Mr. C. E., has been appointed Public Analyst for the Parish of Kensington.

CLUBBE, C. P. BARLEE, L.R.C.P.Lond., M.R.C.S., has been appointed Honorary Surgeon to the Children's Hospital, Glebe, New South Wales.

CRESSWELL, THOMAS HOBBES, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Arncliffe District of the Settle Union.

EAKINS, GEORGE REGINALD, M.D.Brux., L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Honorary Consulting Physician to the Echuca Hospital, Victoria.

ESSER, HENRY C., M.R.C.S. & L.S.A.Lond., has been appointed House-Surgeon to the Birmingham and Midland Eye Hospital.

GROOM, HENRY THOMAS, M.R.C.S., L.S.A.Lond., has been appointed Assistant Medical Officer to the Walton Workhouse, West Derby Union.

HARLAND, Mr. R. H., has been appointed Public Analyst for Greenwich.

HICKS, BRAXTON, M.D.Lond., F.R.C.P., F.R.S., has been elected an Honorary Physician to the Royal Maternity Charity.

JOHNSON, CHARLES HENRY, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Fourth District of the Basingstoke Union.

JOHNSTON, M., M.R.C.S., L.R.C.P., L.M.Lond., has been appointed Junior Assistant Medical Officer to the Sussex County Lunatic Asylum, Hayward's-heath.

KING, ARTHUR, L.D.S., has been appointed Dental House-Surgeon to the Dental Hospital of London.

LYON, THOMAS GLOVER, M.A.Camb., L.R.C.P.Lond., M.R.C.S., has been appointed Clinical Assistant to the Hospital for Diseases of the Skin, Blackfriars.

MANSELL-MOULLIN, JAMES ALFRED, M.A., M.B.Oxon., M.R.C.P., M.R.C.S., L.S.A.Lond., & L.M., has been appointed Assistant-Physician for Diseases of Women at the West London Hospital, vice Albert Venn, promoted.

PARKES, LOUIS, M.D., S.Sc. C.Lond. Univ., has been appointed Medical Officer to the Mansion House Council on the Dwellings of the Poor, vice B. A. Whitelegge, M.D., B.Sc., resigned.

POWELL, JOHN JOS., M.B.Lond., M.R.C.S., has been appointed House-Physician to the Queen's Hospital, Birmingham.

PRIEST, JAMES DAMER, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Waltham District of the Edmonton Union.

SAUNDBY, R., M.D., C.M.Ed., M.R.C.P.Lond., has been elected Physician to the Birmingham General Hospital, vice Dr. Russell, resigned.

SAUNDERS, W. SEDGWICK, M.D., L.R.C.P.Ed., M.R.C.S., has been reappointed Medical Officer of Health and Public Analyst for the City of London.

SMITH, Mr. C. R., has been appointed Deputy Assistant Dental House-Surgeon to the Dental Hospital of London.

STEELE, RICHARD, L.R.C.P.Ed., M.R.C.S., has been appointed Medical Officer to the Cottage Homes, Leicester Union.

VENN, ALBERT, M.D.Aberd., M.B. & C.M., M.R.C.P.Lond., has been appointed Physician for Diseases of Women at the West London Hospital, vice Alfred Wiltshire, F.R.C.P.Lond., M.D. St. And., resigned.

VIPOND-CROCKER, J. C., L.D.S., has been appointed Assistant Dental House-Surgeon to the Dental Hospital of London.

WALKER, E. B. C., M.B., M.C.Ed. (late Junior Assistant Medical Officer), has been appointed Senior Assistant Medical Officer to the Sussex County Lunatic Asylum, Hayward's-heath.

WILLIAMSON, HARRY MAJOR LECKENLY, L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer for the Clapham District of the Little Union.

Births, Marriages, and Deaths.

BIRTHS.

GIFFARD.—On the 27th ult., at Pavilion-parade, Old Steine, Brighton, the wife of Douglas W. Giffard, M.R.C.S., of a son.

LARKIN.—On the 24th ult., at Grove-park, Kent, S.E., the wife of F. G. Larkin, L.R.C.P., M.R.C.S., of a son.

O'BRIEN.—On the 26th ult., at Peshawur, Punjab, India, the wife of Surgeon-Major T. B. P. O'Brien, Army Medical Department, of a son.

PARSONS.—On the 28th ult., at Whitworth-road, South Norwood, the wife of H. Franklin Parsons, M.D., of a daughter.

ROOME.—On the 1st inst., at Fluelen House, Guildford, the wife of Henry A. Roome, M.B., of a son.

MARRIAGES.

BENJAFIELD—WILKINSON.—On the 29th ult., at New College Chapel, London, William B. Benjafield, M.B.Ed., of Edmonton, to Miriam Alice, daughter of Joseph Wilkinson, of Foley-avenue, Well-walk, Hampstead-heath.

LUKIS—STEWART.—On the 20th ult., at Cawnpore, India, Charles Parley Lukis, Surgeon Bengal Medical Service, to Lilian, daughter of John Stewart, Esq., of Ardvorlich, Perthshire, Colonel Royal Artillery, Cawnpore.

PORTER—CHAMBERS.—On the 29th ult., at St. George's, Hanover-square, J. Francis Porter, M.D., to Edith S., only child of G. Chambers, Esq.

SPARROW—PILLING.—On the 29th ult., at St. Luke's Church, Southport, Robert Lancelot Sparrow, M.R.C.S., to Louisa, younger daughter of the late James Pilling, Stone Hill, Rochdale.

DEATHS.

BRAITHWAITE.—On the 31st ult., at Clarendon-road, Leeds, William Braithwaite, M.D., in his 78th year.

BRUCE-JOY.—On the 28th ult., at Pembridge-gardens, Bayswater, William Bruce-Joy, M.D., formerly of Leeson-street, Dublin, in his 65th year.

CAMERON.—On Dec. 30th, 1884, at his residence, Main-street, Georgetown, Demerara, British Guiana, Alexander Gordon Matheson Cameron, M.D., youngest son of the late Capt. John Cameron, 79th (Cameron) Highlanders, aged 58.

MARTIN.—On the 19th ult., at Oundle, J. C. Martin, M.R.C.S., aged 68.

MCNAY.—On the 29th ult., at Scardeburg, Bournemouth, Annie Elizabeth, eldest surviving daughter of the late Thomas F. McNay, M.D., F.R.C.S., of Newcastle-upon-Tyne. No cards.

MIDDLEDITCH.—On the 29th ult., at his residence, Ladbroke-grove-road, W., Henry Arthur Middleditch, M.D., M.R.C.S., L.S.A.Lond., aged 62.

PARROTT.—On the 31st ult., at his residence, Clapham-common, S.W., John Parrott, M.R.C.S., in his 65th year.

WILLIAMS.—On the 18th ult., at Zanzibar, of malarial fever, John Alexander Williams, M.B., M.R.C.S., Medical Officer to Her Majesty's Consulate, aged 29. By telegram.

WORTHINGTON.—On the 31st ult., at Lowestoft, William Collins Worthington, F.R.C.S., in his 85th year.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths*

Medical Diary for the ensuing Week.

Monday, February 9.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M. each day, and at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M. each day, and at the same hour.

ST. MARK'S HOSPITAL.—Operations, 2 P.M., and on Tuesdays at the same hour.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

MEDICAL SOCIETY OF LONDON.—8 P.M. Mr. Henry Morris will open a Discussion on some points in the Surgery of the Kidney.—Mr. James Startin will show Cases of Lupus cured by Caustics.

Tuesday, February 10.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 P.M., and Thursdays at 2 P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M., and on Fridays at 2 P.M.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M., and on Saturday at the same hour.

ROYAL INSTITUTION.—3 P.M. Prof. Moseley: Colonial Animals.

ANTHROPOLOGICAL INSTITUTE OF GREAT BRITAIN AND IRELAND.—8 P.M. Mr. H. H. Johnston: The People of East Equatorial Africa.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—8.30 P.M. Dr. D. Lowson: Case of Displacement and Fracture of the Axis.—Mr. Richard Davy: The Radical Cure of Club-foot, with exhibition of Cases.

Wednesday, February 11.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M., and on Saturday at the same hour.—Ophthalmic Operations on Tuesdays and Thursdays at 1.30 P.M.

ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Skin Department: 9.30 A.M., on Tuesdays and Fridays.

ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M., and on Saturday at the same hour.

LONDON HOSPITAL.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.

GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M., and on Saturday at the same hour. Skin Department: 1.45 P.M., and on Saturday at 9.15 A.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

HUNTERIAN SOCIETY.—7.30 P.M. Annual Meeting.—8 P.M. Oration by Dr. F. Charlewood Turner.

EPIDEMIOLOGICAL SOCIETY OF LONDON.—8 P.M. Major K. McLeod: The Prevalence of Epidemic Roseola in Calcutta.

ROYAL MICROSCOPICAL SOCIETY.—8 P.M. Presidential Address, illustrated by Lantern Microscope: On the Life History of a Septic Organism hitherto unrecorded.

Thursday, February 12.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Surgical Consultations, 1.30 P.M.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and on Friday at the same hour.

NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

ROYAL INSTITUTION.—3 P.M. Prof. Dewar: The New Chemistry.

THE PARKES MUSEUM OF HYGIENE.—8 P.M. Dr. Percy Frankland: The Selection of Water for Domestic Supply.

Friday, February 13.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1.30 P.M.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.

MEDICO-PSYCHOLOGICAL ASSOCIATION.—4 P.M. Dr. Hayes Newington: The Influence of Minor Uterine Troubles on Insanity.—Dr. Hack Tuke: The Insane in the United States.

CLINICAL SOCIETY OF LONDON.—8.30 P.M. President's Address.—Dr. Hale White: A Case of Myxœdema, with a Post-mortem Examination.—Dr. Carrington and Dr. Hale White: Two Cases of Phlegmonous Pharyngitis.—Dr. Hughes Bennett: A Case of Locomotor Ataxy without Disease of the Posterior Columns of the Cord.—Dr. Seymour Taylor: A Case of arrested Rickets (living specimen).

ROYAL INSTITUTION.—9 P.M. Sir John Lubbock: Forms of Leaves.

Saturday, February 14.

KING'S COLLEGE HOSPITAL.—Operations, 1 P.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—3 P.M. Prof. John Marshall will deliver the Hunterian Oration.

ROYAL INSTITUTION.—3 P.M. Mr. G. Johnstone Stoney: Operations which go on between Molecules.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe, or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

EAU DE TABLE.

IT has often been a matter of surprise that an agent of such prime importance in vital processes as oxygen undoubtedly is should so long have remained in a comparatively obscure position as a remedial agent. But the fact is, that in its ordinary form oxygen gas does not seem capable of direct employment with any special advantages. The attempt now made by Messrs. Brin Frères of Paris-Passy to introduce into use a distilled water saturated with oxygen must be regarded in a very favourable light. The profession in France seem to have taken eagerly to this new preparation, and it is being largely employed in hospitals for the purposes of inhalation in various diseases. In the preparation of the "eau de table" filtered water is stated to be used and then saturated with pure oxygen. In a cylinder capable of supporting a pressure of 300 lb. to the square inch a certain quantity of oxygen is dissolved in the water, while the excess of gas which has not been taken up remains imprisoned in the water, which is then put into bottles and syphons. The water is used for ordinary drinking purposes, and, mixed with wine or other liquors, is said to develop their aroma. It appears to have been useful in many diseases of the digestive and urinary organs.

Dr. Robert Bell.—We shall be happy to give attention to the matter on receipt of the sample.

Mr. Joseph Abbott.—We are unable to comply with the request.

"PRURITUS VULVÆ."

To the Editor of THE LANCET.

SIR,—In compliance with the request of "M.D." for suggestions in the treatment of pruritus vulvæ, I would refer him to the history of a case recorded by me in THE LANCET of Dec. 6th, 1884, under the heading of "The Spinal Cord in Health and Disease" (Case 14), and would advise that he treat his patient in a similar manner, and to kindly inform me of the result either privately or through THE LANCET. Your correspondent does not state whether his patient's ailment is complicated with pregnancy; but I should regard its concomitance or otherwise immaterial to the issue, as, if my theory of the causation of the disease be correct, and that it is due to central and reflex agency, no merely local medication can effect a cure. My plan is simply vesication over the spine at the region of the fourth and fifth dorsal vertebræ, which limited zone I have demonstrated stands in pathological relation with disease in many distant organs.—Yours truly,

Belfast, Feb. 3rd, 1885. ALEXANDER HARKIN, M.D., L.R.C.S.

M.D. (S.E.) would do well not to use the ordinary form of death certificate. He cannot legally certify.

Mr. George Abbott (Tunbridge Wells).—Next week.

Mr. Spreull (Dundee).—The letter has not been preserved.

OVARIOTOMY IN CHINA.

THE ovariotomy recently performed at Shanghai by an American lady doctor has been made the subject of an illustration in a pictorial magazine published for the instruction and amusement of natives by a Chinese printing establishment in Shanghai. The drawing is curious in many respects, none of its details being correct, and is accompanied by an explanation in which Chinese doctors are branded as humbugs who shelter themselves behind the inevitable course of nature when a patient dies, and bombastically take credit for great skill when nature in spite of them brings about a cure.

Messrs. Ferguson and Co.—Galton's whistles can be obtained, properly graduated, of Mr. J. P. Hawksley, acoustical instrument maker, 357, Oxford-street, W.

Practitioner.—It is impossible to lay down an inflexible rule. It is better to follow the custom which has prevailed in the place.

MEDICAL PRACTICE IN THE ARGENTINE REPUBLIC.

To the Editor of THE LANCET.

SIR,—In your issue of Jan. 24th there is a paragraph referring to the Argentine Republic as an El Dorado. If this is so, things must have changed since I was there in 1865, though, according to the letter quoted from the *South American Journal*, matters seem much the same. I would strongly urge would-be participators to make further inquiries. It is quite true that there is a Government Medical Board, of which every (passed) medical man resident in Buenos Ayres is a member, to whom is entrusted the examination, in Spanish, of all foreigners desiring to practise in the Republic. It did not follow, however, that passing or failure at the examination was any criterion of the knowledge of the candidate. It was an open secret at the time I am writing of that unless the candidate had entered into partnership with one of the resident medical men, therefore an *ex-officio* member of the Examining Board, either paying a considerable sum for the position, or in some way giving an equivalent, his chance of passing was very limited. I may perhaps be allowed to illustrate the fact by my own case. I was offered £500 per annum to become an assistant to an Englishman having English qualifications and qualified according to the laws of the Republic, with the further advantage of a partnership after five years, on condition that I passed the Medical Board. This seemed so good that I was on the point of accepting the offer, when a friend, an old resident in Buenos Ayres, informed me that the medical man in question had already tempted others in a similar way; but, on presenting themselves for examination, the result was uniform—they were plucked. It was openly suggested that an arrangement had been come to between members of the Board by which some member other than his partial plucked the candidate, and expected a similar return from his brother members when occasion required. Without passing this examination you have no *locus standi*, cannot recover fees, and, moreover, are liable to prosecution in any unsuccessful case.

I very much doubt if such sums as are mentioned have ever been paid, save in some exceptional case, though no doubt fees are higher than with us. Expenses, too are very heavy, greater even than in England, and very few of the most successful practitioners seem to be able to leave their families free from all anxiety in pecuniary matters at their decease. I am sorry to throw cold water on anything that gives a hope that the profession may find a "trump" at last; but perhaps a word of warning may lead enthusiastic beginners to realise that there are two sides to the story. Persons and things may have changed during the last twenty years; but such a close borough is not likely to have yielded its secrets without a hard fight, and anyone who knows South American politics will not be surprised if something akin to what I have described has survived to the present day.

I may add, the dollar when not specie represents 2½*d.* in this depreciated state. While I was there the Government fixed the value of the English sovereign by authority—viz., 122½ dollars paper.

I am, Sir, yours faithfully,

Jan. 31st, 1885. J. R. L.

Mr. J. Lawrence.—Messrs. Richards, Glanville and Co., 4, Brown's-buildings, St. Mary Axe, E.C.

Dr. Gilbert (Louvain).—There is no smaller English work than Green's Manual of Pathology, or Woodhead's Practical Pathology.

Dr. Moyer's paper will appear in an early number.

LOCK HOSPITALS IN INDIA.

To the Editor of THE LANCET.

SIR,—It is stated, apparently on good authority, in *Allen's Indian Mail* Jan. 24th, that, as an experimental measure, it has been decided to close the lock hospitals at a number of stations in the Bengal Presidency, among the rest, those at Allahabad and Cawnpore. I am aware that for some time past this view has been impressed on the Government by some of the leading sanitary authorities in India, and at last apparently with success. Allow me to say that, having had many years' experience of the working of lock hospitals in India, especially at Cawnpore, I consider the step now taken to be not only a retrograde one, but also one fraught with danger to the soldier and loss to the State. If this step be carried out we may expect a large increase of sickness from the most intractable form of disease, and when too late the folly of the step will be apparent.—I am, Sir, your obedient servant,

Dublin, Jan. 25th, 1885. J. B. HAMILTON, M.D., Surgeon-Major, Medical Staff.

TESTS FOR HEARING.

PROFESSOR A. GRAHAM BELL has recently added to the instruments for measuring the acumen of the senses by the construction of an apparatus for determining the capacity of the ear. It has been described as a telephone receiver with a rotary circuit breaker revolving at a sufficiently high speed to produce a note of uniform pitch to the listener at the telephone. By means of increasing the distance between two coils in the circuit the current is diminished, and the sound at the telephone weakened until inaudible. By means of a scale showing the distance between the coils a standard is obtained for the representation of the acuteness of the hearing. It has been found that equal capacity of both ears is exceptional, most persons having a marked difference in this respect. From the results of a number of tests among the public school children in New York, Professor Bell estimates that 10 per cent. have slight defects in hearing, and that 1 per cent. are too deaf to receive benefit from the ordinary modes of instruction.

Mr. E. J. Gurdon.—The London office of the *South American Journal* is at 37, Walbrook, E.C.

SOUTHERN CALIFORNIA AS A HOME FOR CONSUMPTIVES.

To the Editor of THE LANCET.

SIR,—Some years ago, when wintering at Mentone, my attention was directed to an English institution there of a semi-charitable nature for the benefit of consumptives. The plan on which it was conducted was as follows: Patients were received for a weekly payment of, I think, £1 1*s.*; the balance necessary for the support of the institution was obtained by voluntary contributions from the charitable public.

I desire to draw attention to Southern California as a field for a charitable institution similar to the above. The advantages of this locality, as compared with the south of France, may briefly be stated as follows:—1. The climate is for consumptives the best in the world; it is not too hot in summer, and is not as cold or as wet as Mentone in winter. 2. Persons possessed of some capital can purchase a few acres of land, and make a living by fruit farming. 3. Persons without means will have a fair chance of getting some light employment which will enable them to support themselves. 4. Persons suffering from consumption should have some occupation to prevent them dwelling on their physical infirmity; the out-door occupation of cultivating, or superintending the cultivation of, a small tract of land is probably the best. Land can be purchased here in small or large tracts; and if a judicious purchase be made, it will be a profitable investment, apart from the consideration mentioned above. 5. Many persons in delicate health go to Mentone for one winter and experience some benefit; not being able, however, to leave their homes and business for a length of time, the improvement proves to be temporary only. Here permanent homes can be made, and a permanent cure be effected. There are thousands of persons in this country—your correspondent among the number—who came here in the incipient stage of consumption, and who are now perfectly strong and well. 6. If sufficient money can be raised to build and furnish a consumption hospital here, I am confident that it could be maintained at less cost than the hospital in Mentone. A building capable of accommodating 200 patients could be erected and furnished for about £10,000. A suitable site, either at Pasadma or San Gabriel, in Los Angeles County, would be donated by a British subject resident here.

It may be objected that the distance from England to California is too great. In reply to this possible objection I have only to say that anyone whose lungs are seriously attacked must make up his mind to winter out of England for four or five years. From London to Los Angeles viâ Panama will not cost more than two round trips from London to Mentone. I beg to urge charitable people in London to form a provisional committee, and, if satisfied of the feasibility and advisability of the plan I have suggested, to solicit subscriptions in aid of the undertaking. A considerable amount would, I am sure, be subscribed here. Subscriptions would also be readily obtained in Canada; as many Canadians are annually driven here by the severity of the Canadian climate. I will be happy to furnish any and all information and assistance in my power, as also will the Rev. A. G. L. Trew (formerly of St. James's Cathedral, Toronto, Canada), rector of San Gabriel, Los Angeles County.

I am, Sir, yours truly,

Los Angeles, California, Jan. 1st, 1885. C. WHITE MORTIMER, British Vice-Consul.

Mr. S. S. Noakes.—Amidon's Student's Manual of Electro-Therapeutics (G. P. Putnam's Sons, 25, Henrietta-street, Covent-garden, London).

BLEACHING OF THE HAIR.

To the Editor of THE LANCET.

SIR,—In Quain's Dictionary, page 576, it is stated by the late Sir Erasmus Wilson that hair may turn white in a few hours from mental disturbance, and that this is caused by the rapid development of gaseous fluid within the substance of the hair, obscuring the pigmentary granules. I should much like to know if any of your readers have ever seen or known of a well-authenticated case, and, if so, was the bleaching permanent, or did the gaseous cloud gradually roll away and allow the natural colour to reappear? It seems impossible that hair, perhaps many inches long, could be altered by any change that takes place in the body; not even death itself affects it.—I am, Sir, yours truly,

Gillingham, Dorset, Feb. 2nd, 1885. T. WOODS.

Mr. L. Macdona.—We should advise our correspondent to put his questions and his views before the Secretary of the Edinburgh Medical Missionary Society. Druitt's is a very good book; so are Bryant's Surgery, Roberts on Medicine, and Bristowe's book.

Mr. W. A. Ellis.—We may safely leave S. W——'s nonsense to the care of C. R. G—— and other local champions of vaccination.

E. J. L.—The cases described by our correspondent are such as bring the coroner's office into contempt.

MEDICAL ETIQUETTE AT THE EAST-END.

To the Editor of THE LANCET.

SIR,—About a fortnight ago I was called at 3 A.M. to attend a lady patient living close to my house. The child having been born suddenly, the husband naturally ran for the nearest medical man, as the practitioner engaged to attend lived at a considerable distance. I went at once, and attended to the patient and child. When leaving, the husband asked my fee; but I declined to accept any, stating that under the circumstances of the case I attended for the medical man engaged (who was a stranger to me), from whom I expected to hear as soon as he took charge of the case. Not having heard from, or received any acknowledgment for my services from, the said medical man, who has driven past my door on several occasions since then, I would feel obliged if you would kindly let me know through the medium of your columns, should such a case occur again, whether I would be justified in accepting a fee for my attendance, or refusing to attend for the same practitioner.

I am, Sir, yours truly,

Jan. 27th, 1885. A SUBSCRIBER.

*** Our correspondent acted most properly, and on none but the very highest principles can he be expected to act so again for the practitioner in question.—ED. L.

Dr. Thompson (Rome).—We hope to be able to find room for the paper in an early number.

A. B.—The method is undignified.

TINCTURE OF ACONITUM FEROX.

To the Editor of THE LANCET.

SIR,—In reference to Dr. Cullimore's letter on the above in your last issue (page 235), I shall be glad if you will allow me to make a correction as to its strength. I prepared it 1 in 8 of rectified (not proof) spirit, the same strength as the B.P. tincture of aconitum napellus, so as to have its action compared with the latter.—Yours obediently,

New Cavendish-street, W., Feb. 3rd, 1885. WM. MARTINDALE.

ERRATUM.—In line 9 of the report of cases under Dr. Elder's care at the Women's Hospital, Nottingham, page 202, for "two months later" read *twelve* months later.

Annual Address

DELIVERED AT THE

OBSTETRICAL SOCIETY OF LONDON,

On Wednesday, February 4th, 1885,

BY HENRY GERVIS, M.D., F.R.C.P.

GENTLEMEN,—Once again from this chair, and for the last time, it devolves upon me to briefly review our general position as a Society, to offer you some account of our work during the year which closes to-night, and to pay the customary tributes to the memories of those of our Fellows whom we have lost.

As regards the general position of our Society, I have again to speak to you in the full strain of congratulation. During the past year we have welcomed into our ranks 67 new Fellows, a considerably larger increase than the average of many preceding years; and although against this large increase we have to place our losses by death, amounting to 10, and those by resignation and erasure, reaching 31, our numbers now stand at 722, forming a larger constituency than that of any other London Society, unless, in the case of the Royal Medical and Chirurgical Society, its non-subscribing Fellows are included, when its numbers slightly exceed ours, the Pathological Society coming next with 684. The attendance at our meetings has been everything we could wish, and on more than one occasion in the summer when there were great attractions elsewhere the loyalty of our Fellows was such that no falling off occurred in the numbers present. I may perhaps, in passing, be pardoned for expressing my gratification—a gratification, I am sure, in which all present share—at the regularity with which so many senior Fellows of the Society, including nearly all those who have filled the chair, attend our meetings. After long years of splendid work and service, when temptations to ease become somewhat strong, still evening after evening they have been here, encouraging us by their presence and assisting us by their knowledge and experience. Respecting our finance, you have heard from the report of our treasurer the gratifying intimation that after payment of all our liabilities and the investment of nearly £100, we close the year with a balance of £237 and with the amount of £1400 in consols. The report of our hon. librarian is also highly satisfactory. A library of 3406 volumes is no small addition to the equipment of a Society, and the advantages offered by our rooms in Berners-street can hardly be surpassed. In comfort and convenience they approach, indeed, those establishments which recently a great statesman spoke of as temples of luxury and ease. As regards our midwifery examinations, the report of our chairman will have told you much that is encouraging. Our diploma is becoming increasingly popular, and, as you have heard, no fewer than sixty-three candidates presented themselves during the past year for examination, of whom forty-nine passed, raising the total number of midwives in possession of our certificate to 247. Among the numerous claims our Society has on the profession—and in twenty-five years few societies, if any, have established greater,—not the least is the impetus given through our Midwifery Board to the higher education of midwives.

Now, as to our work during the year that has passed. In briefly reviewing it I have first to recall to you the paper read by Dr. J. Williams at our meeting in March on "Corroding Ulcer of the Os Uteri," by common consent an excessively rare disease, almost undescribed by systematic writers, and which probably has often been mistaken for rodent ulcer, or some form of epithelioma. The particulars of Dr. Williams's cases, however, their clinical features and the results of microscopical observation appear to separate them distinctly from cancerous affections; less distinctly from lupus - a disease, indeed, thought by some speakers to be probably identical with the disease described by Dr. Williams.

The early part of our meeting in April was occupied by Dr. Francis Neugebauer's exhibition of specimens of vertebræ from cases the subjects of spondylolisthesis, and by his personal exposition of his views. In Dr. Neugebauer's opinion the slipping forwards of the vertebræ, characteristic of the disease, occurs not as a result of any dyscrasia such as rickets or osteo-malacia, or of any bone disease, inflammatory or specific, as caries or ostitis, but by the weight of the trunk, especially when this is increased by unusual stoutness or frequent pregnancies, acting in virtue of certain surgical predispositions or lesions; and, further, that the deformity is not limited either to the sacro-lumbar articulation or to any age or either sex. The surgical predispositions he believes to be most influential are—(1) a congenital arrest of development, produced by defective ossification in the vertebral arch, and (2) complete or incomplete fracture of the arch with imperfect union. These conditions permit a sliding forwards of the anterior part of the last lumbar. But he considers also that the last lumbar vertebra may sometimes not merely partly slide forwards, but be totally displaced forwards as a result of fracture of its articulations with the sacrum; and this he terms "glissement en masse." In a word, both the less and more pronounced forms of spondylolisthesis he considers traumatic in origin.

The same evening we had Mr. Doran's suggestive paper on the genealogical relations between prolapse of the vagina and intestinal hernia, illustrated by three pedigrees of patients who suffered from prolapse of the anterior wall of the vagina, and in whose families a remarkable tendency to other hernias existed. The paper, as a whole, strongly supported the view, now largely held, that not merely prolapse of the vagina, but prolapse of the uterus itself, is essentially a hernia, "with a definite sac, definite boundaries, and definite contents."

Dr. Kilner concluded an interesting evening by a valuable communication on the use of the induced current in parturition. He not only uses electricity for strengthening uterine contractions when feeble and checking post-partum hæmorrhage, but also very largely for the relief of the pain of labour, as an equaliser of the pulse, and as a preventive of undue exhaustion. He showed a very small and easily portable coil battery, which he used in ordinary midwifery cases; and if similar results can be obtained by other and less specially skilled observers, there can, I think, be no doubt that in electricity in this form we gain an agent which will be a valuable adjuvant in the ordinary management of labour.

At the meeting in May Dr. Arthur Mitchell brought before the Fellows the result of his wide experience as to the influence of mental emotion in women as a cause of idiocy in the offspring. In many cases in which this was assigned as a cause by the mother, Dr. Mitchell thought the evidence insufficient, but in some he expressed his belief that it was a true cause, especially if the state of mental emotion had been a protracted one, although, possibly, its influence on the intellect of the child might be indirect, and through its influence on the bodily health of the mother. In the debate which followed Dr. West thought the verdict must still be "not proven," but Dr. Fletcher Beach, Dr. M. Duncan, and other speakers coincided with Dr. Mitchell's view, that there was a certain proportion, at present unsettled, of cases of idiocy in which mental emotion in the mother had been the determining cause.

In connexion with Dr. Mitchell's paper I may, perhaps, be pardoned if I venture to call attention to the fact that in the work of this Society we have strangely overlooked the department of the diseases of children. And yet at its formation it was expected that children's diseases would occupy a prominent place in our proceedings, and in our bye-laws and regulations the first section of the first chapter states that the Obstetrical Society of London is instituted for the promotion of knowledge in all that relates to obstetrics and diseases of women and children. But in our twenty-five years' work I can recall, excluding this evening's paper on Ophthalmia Neonatorum, scarcely half a dozen communications on infantile diseases. Dr. Tanner once brought forward the subject of Infantile Syphilis; Dr. Playfair of Empyema in Children; Dr. Madge narrated some cases of Pericarditis and Chronic Hydrocephalus; Mr. Curgenven read a paper on Hereditary Convulsions, and Dr. Wynn Williams gave us an interesting account of his treatment of Diphtheria, a monograph to which to this day I feel much indebted when brought into contact with that disease. With possibly one or two additional papers which I may have overlooked, and an occasional discussion in connexion with the exhibition of some specimens, this constitutes the whole of our work in this important department.

In days gone by I have heard it said occasionally that the

one fault of our Society, if it had a fault, was its too great devotion to gynæcology, and that there was just a suspicion of a tendency to sameness and repetition in our discussions; that, come to a meeting when he might, a practitioner was sure to hear us discussing some gynæcic minutiæ, or, by way of change, some obstetric rarity, and, less often than he could have wished, those commoner subjects which are met with in daily practice and at the bedside of the puerperal woman. Be this as it may, though for my own part I must plead a still deep interest even in such well-discussed subjects as the symptomatology and treatment of uterine flexions, there is, I think, no doubt that if some of those of our Fellows who practise generally and are having the daily care of children would bring before us some of the results of their observations and experience in these diseases, it would add much to the utility of our meetings, give variety to our discussions, and assist in the more complete fulfilment of the objects proposed at the foundation of our Society. At this same meeting in May we had the notes of a case of extra-uterine gestation by Dr. Mathieson of Ontario, in which a living child was delivered by vaginal incision from a cyst by the side of the uterus. A considerable discussion followed, not merely as to the advisability of the particular operation performed, but also as to the exact character of the case, several speakers thinking it to be a gestation in a variety of double uterus, or an interstitial gestation rather than one truly extra-uterine.

At the June meeting we had important contributions from two past presidents of the Society. Dr. Playfair gave careful and detailed particulars of two cases, in which he believed that spontaneous absorption of thrombi in the pulmonary artery had taken place; and Dr. Matthews Duncan read a paper on "Fœtal Revolutions" as distinct from its rotations, and described the various forms of revolution observed in different presentations and conditions of the fœtus.

At the July meeting the report of the committee on Dr. F. Neugebauer's specimens of Spondylolisthesis was read. This committee included, besides two of our own Fellows, Dr. Barnes and Mr. Doran, two who were visitors on the evening when Dr. Neugebauer was present, Mr. W. Adams and Mr. Noble Smith, to all of whom our best thanks are due for the trouble and time they gave to the consideration of the subject. Their report confirmed the view of Dr. Neugebauer that spondylolisthesis arises from the traumatic slipping away of the anterior half of one or more vertebræ, notably of the fifth lumbar, from the posterior half. Dr. J. Williams then gave a detailed account of the progress of involution in the puerperal uterus in a case in which both the ovaries had been removed; one three years previously, and one during the labour which preceded the involution in question. Involution was at first distinctly delayed seven weeks after delivery, the uterus being of the size usual in the fourth week; but seven months after delivery the condition termed super-involution had occurred, the uterus was smaller than would be normal even in a nullipara, and measured but two inches in length. At the same meeting Dr. M. Duncan, in association with Dr. Hurry, read a very interesting and important paper, illustrated by numerous specimens and drawings, on the subject of "Fœtal Flexions and Extensions during Pregnancy," and their bearing on the etiology of malpresentations.

At our meeting in October, delayed a week by the occurrence of the 1st on a Wednesday, we had from Mr. Hopkins Walters an account full of interest of a case in which the uterus with one ovary and tube had been forcibly torn away by the midwife in attendance on the case; and in addition to these particulars Mr. Walters gave a summary of a large number of cases more or less parallel in which accidental avulsion of the uterus had occurred. In some of these the uterus had been inverted and an erroneous diagnosis of tumour had led to the occurrence; in others, and in the fewer number, as in Mr. Walters's case, no previous inversion had existed. Various theories as to the *modus operandi* were suggested by those who took part in the debate, such as the introduction of the hand into the peritoneal cavity through a rent in the posterior wall of the vagina, and so pulling the uterus out by force from above; too forcible expression by pressure on the lower abdomen; retroverting the uterus first by the introduction of more or less of the hand into its cavity, and then tearing it away by the purchase so obtained; and, lastly, Mr. Walters's own idea, that it was at first detached, partially at all events, by thrusting the hand into it for the removal of the placenta without making adequate counter-pressure on the hypogastric region, and then torn entirely away, partly in panic and partly through ignorance. In whichever of these ways the accident occurred in this particular case, speaking generally there can, I think, be no question that in any and every case the forcible avulsion of the uterus after delivery is a proceeding of the utmost gravity and entailing the most serious responsibility.

At our meeting in November Dr. Graily Hewitt read a paper illustrating his views on the close connexion he believes to exist between distortion and displacement of the uterus in pregnancy and severe sickness. In addition to cases occurring in his own practice, Dr. Hewitt brought before us an interesting series of ten cases published by Professor Horwitz, and others by other writers, making in all thirty-two cases, in which more or less displacement of the uterus, both general and axial, was associated with vomiting of a severe type in early pregnancy. In all these cases when attempts were made to raise the uterus from its displaced position, and the attempt was successful, the vomiting ceased, but when the attempt failed death resulted, except where artificial or spontaneous abortion took place. The conclusions which Dr. Hewitt tabulated were that nearly always sickness was due to some error in the condition of the gravid uterus itself; that this error was generally some interference with its normal expansion and growth, associated sometimes with its detention in the bony pelvis, generally as a result of flexion or version, or less commonly from the presence of some pelvic tumour, and sometimes, but less frequently, in association with undue hardness about the os and cervix. Very varied views were expressed by those who took part in the debate, which occupied two evenings, but the more general opinion appeared to be that displacements and distortions of the uterus were less influential factors in the etiology of pernicious sickness than Dr. Hewitt thought, and that even the large number of cases brought forward were not sufficient to permit as yet any dogmatic generalisation on the subject.

It was not the wish of the Fellows present to allow the debate to occupy a third evening, and so it happened that several who were anxious to speak, myself among the number, had not the opportunity. I am the more wishful, therefore, in this reference to the work of that evening to say how indebted we are to Dr. Hewitt for the very considerable addition he has made, in his paper as well as in the tables he was good enough to print for our use, to the facts on which to build our views of these rare cases. Very briefly my own experience has been this: that when conception has taken place in women the subject of uterine flexion, and particularly of anteflexion, severe enough to have led to preceding dysmenorrhœa, and so been noted beforehand, but not severe enough to have induced sterility, there has nearly always been an increased tendency to early and very troublesome sickness, and often to other reflex derangements, such as pyrosis, ptyalism, and various neuroses. Flexions of the uterus, gravid and non-gravid, lead, I believe, in a considerable proportion of cases to a pathological hyperæmia of the uterus. So, it may be, that this tendency to sickness which prevails in cases where flexion co-exists is not due to flexion as flexion, but to the pathological hyperæmia, which it, in common with other faulty conditions, such as endometritis, ovaritis, or fibroids, is apt to induce. In incarceration of a gravid uterus, whatever be the cause of the incarceration, this pathological hyperæmia would be still more increased, and the reflex results proportionately heightened. As regards Copeman's method, I should like, also, to take this opportunity of stating that my experience of it in cases of uncontrollable vomiting, by which I mean vomiting beyond the control of any medicinal or dietetic treatment, when associated with anteflexion, has been distinctly satisfactory. I have no experience of it apart from this association.

And, lastly, at our meeting in January, Dr. W. Duncan brought forward in a thoughtful and comprehensive paper the subject of extirpation of the uterus. Besides giving details of two cases in which he himself had performed the operation, and discussing the subject generally, Dr. Duncan gave a tabular statement of all the known cases in which the entire uterus had been removed either by the abdominal or the vaginal operation, amounting in the former to 137, with a death-rate of 72 per cent., and in the latter to 276, with a death-rate of 28·6. These tables alone must have involved considerable work and research, and for his kindness in printing them so as to further the completeness of the

debate, we are greatly in his debt. The debate being adjourned, I am not in a position to sum up the final result, but so far as the proceedings of one evening extended, every speaker, whether basing his opinion, like Dr. J. Williams and Mr. Thornton, on personal experience of the operation, or, like Mr. Doran, on the anatomical relations of the uterus, especially with reference to the arrangements of its lymphatic system, expressed himself in terms generally adverse to the operation. This, indeed, was the conclusion at which Dr. Duncan had himself arrived, at all events for every case of cancer involving only the vaginal cervix. The other conditions for which extirpation had been carried out, such as prolapsus and certain cases of endometritis, were not touched upon in the debate, but I shall be surprised if much support is given to such procedure by any speaker at the next April meeting.

This, gentlemen, is but a very brief and imperfect sketch of the more important papers and discussions of the session, and far from represents the sum total of our work. At every meeting we have had numerous specimens exhibited, some of extreme and general interest, some of great rarity, nearly all important and instructive. Indeed, after two years of close attendance at our meetings I am not sure whether I have not learned as much from what I have seen as from what I have heard; but, at the same time, with the wealth of contributions in the hands of our secretaries and the life and vigour which characterise our Society, it is impossible to allow the exhibition of specimens to extend much, at all events, beyond the half-hour allotted to them. Possibly, if we were to adopt the plan of the Pathological Society and have card specimens passed round, specimens with short descriptive accounts appended, and intended for inspection rather than discussion, the difficulty of getting in all we wish would be at least partially met. Regarding, then, our work as a whole, the papers read—some in the highest sense scientific, some more practical, and some chiefly clinical—the specimens exhibited, including many improvements in instruments and apparatus, and the discussions elicited at uniformly well-attended and often crowded meetings, I think we may fairly claim for our Society, not only that its strength and vigour are unabated, but that it ranks as an educational force of the first importance.

Our losses by death this year are fortunately not so numerous as often they have been; but the list, always too long, includes some well-known names, and others who, although of less wide reputation, were not the less dear to their own circle of relations and friends, to all of whom our respectful sympathy is given.

The first to be taken from us in the early spring was Dr. J. Hickinbotham of Birmingham. He had been a Fellow of the Society since 1867, and last year was elected on the Council. Dr. Hickinbotham had practised in Birmingham for many years, and for the last five had been Physician to the Hospital for Women in that town. He died on February 22nd of acute nephritis, after a few days' illness, at the early age of forty-four. Dr. Hickinbotham was a frequent attendant at our meetings and often took part in our debates. To our Transactions he contributed, in 1878, an interesting case of ruptured uterus, in which the accident occurred from a fall, the patient recovering; and in 1881 he sent us a case of placenta prævia, complicated by the presence of a large fibroid in the uterine wall. Both these cases contained much that was interesting and important. Two other papers by Dr. Hickinbotham I have also by me, one on missed labour and one on accidental hæmorrhage. These also contain thoughtful and original work.

Dr. John Hall Davis, formerly a President of this Society, and up to a short time prior to his death Obstetric Physician to the Middlesex Hospital, died on March 19th at the age of seventy-three. Dr. Davis was the second son of Dr. David Davis, the first occupant of the chair of Obstetric Medicine at University College and a distinguished London obstetrician. Dr. Hall Davis began early to turn his attention to obstetric work, succeeding his father on his death in 1841 as Physician to the Royal Maternity Charity, a post he held with much advantage to the charity and distinction to himself for thirty years. He also at one time gave well-attended private lectures on midwifery at his residence in Bloomsbury. In 1863 he was appointed Obstetric Physician to the Middlesex Hospital and Lecturer on Midwifery in its school. Of our own Society Dr. Davis was an original Fellow, and in 1867 he was elected to the presidential chair, fulfilling its duties with much ability, courtesy, and success. Dr. Davis was the author of one considerable systematic treatise of much value on difficult parturition and of several interesting communications to this Society. It was my good fortune to be associated in three several instances with Dr. Davis in public appointments. I was for a time his colleague on the Royal Maternity Charity, I was secretary of this Society during his presidency, and I was co-examiner with him at the University of London; and I am grateful for this opportunity of offering my sincere tribute to his professional capacity, his uniform courtesy, and his high personal character.

Another original Fellow, Mr. Richardson of Rhayader, died on Aug. 13th, from the result of an accident, at the age of fifty-five. Returning from a professional visit, he was thrown from his dog-cart and instantly killed. I do not remember Mr. Richardson's making any communication to our Transactions, but he evidently took a special interest in obstetric work, as quite recently before his death he read a paper at the Belfast meeting of the British Medical Association on "Uterine Hæmorrhage." He was held in the highest esteem in the neighbourhood in which he practised, his funeral being attended by many hundreds of attached patients and friends, it being, indeed, the largest ever known in Rhayader.

In the same month died Dr. Hugh Cuolahan of Bermondsey, a Fellow since 1867. I had the pleasure of a personal acquaintance with Dr. Cuolahan for many years, and knew him as an admirable specimen of the family practitioner. He was a frequent attendant at our meetings, and was himself an accoucheur of much expertness and ability.

In August also we lost Dr. Westmacott, at the age of seventy-three, and, although not an original Fellow, he, like myself, joined our Society in the first year of its existence, and was a most regular attendant at our meetings. He made but one communication to the Society, and that on the use of the whalebone loop as a fillet, of which he was a warm advocate. Dr. Westmacott's special loop had on one side of the handle a couple of screws with nuts, to permit one end of the loop being removed, so as to facilitate its slipping over the head of the child as it passed the vulval orifice in cases where the perineum was rigid. Dr. Westmacott, who was Obstetric Surgeon to the Paddington Maternity, appears to have generally used this loop in all minor cases of disproportion, and to have had with it a very considerable success. But it was as our draughtsman that Dr. Westmacott was best known to the Fellows of the Society. For twenty-five years he regularly drew for us the admirable woodcuts and plates which enrich our Transactions, and he did it for so modest a recompense that it might almost be spoken of as, on his part, a labour of love. We shall miss much his facile pencil, and the drawings in the first half of the forthcoming volume will regretfully remind us of "the touch of a vanished hand."

There are three other Fellows who passed away during the year of whom I am unable to find any record beyond the simple notification of their deaths. Mr. Malin Sharman of Birmingham died on March 10th. He was Surgeon to the Hospital for Sick Children at Birmingham. He became a Fellow of our Society in 1862. Dr. H. A. Aldred of Westbourne-park died on May 21st. He was a comparatively young Fellow of our Society, having joined us in 1878. On August 28th died Mr. Wykeham Lydall, of Mecklenburgh-square. Since 1869 Mr. Lydall had been one of our Fellows.

And here, gentlemen, I should, following the custom of past years, have concluded these brief obituary notices of those whose loss we deplore, but on Jan. 8th of this year, and so still during my presidency, died one of our Fellows, who was at the same time one of my most valued personal friends, and so, by the courtesy of my successor, I am permitted this evening to place one more wreath on the recent grave of Henry Thomas Lanchester.

[Dr. Gervis then gave a sketch of the career of Dr. Lanchester similar to that which appeared in THE LANCET of Jan. 24th.]

Before quitting this chair, gentlemen, two or three duties yet remain for me to fulfil. In the first place, I have to thank most sincerely all the Fellows of the Society for that uniform kindness and forbearance which they have shown me during the pleasant and not unprosperous two years in which it has been my high privilege to preside at its meetings. Secondly, I wish gratefully to acknowledge the courteous help I have received from the members of the Council and the officers of the Society, and more especially—and to an extent no words of mine can adequately

acknowledge—from our able and untiring secretaries. And yet further, and lastly, I have to congratulate the Society on the acceptance of the office of President by the gentleman who succeeds me. Dr. Potter is known to all here as a graduate of a famous university, as the Obstetric Physician and Lecturer on Midwifery at one of our London schools, and as having been for the three years during which he has held office our most admirable treasurer. In yielding this seat of honour to him I am assured that I shall be followed by a gentleman who is an experienced obstetrician and gynæcologist, who has an accurate knowledge of the affairs of the Society, and who has its interests thoroughly at heart. In quitting, gentlemen, this chair to-night I shall carry with me a hundred pleasant reminiscences, tempered only by the sincere regret that my services have been so inadequate to the presidency of this great Society.

THE QUESTION OF THE IMPORTANCE OF FLEXIONS AND DISPLACEMENTS OF THE UTERUS.

BY GRAILY HEWITT, M.D., F.R.C.P.,
PROFESSOR OF MIDWIFERY AND DISEASES OF WOMEN, UNIVERSITY COLLEGE; OBSTETRIC PHYSICIAN TO THE HOSPITAL.

(Concluded from p. 245.)

REGARDING the objections offered by Dr. Herman to my conclusions on the mechanism of the production of congestion, I would make some remarks. Not long since Dr. John Williams stated that the utero-sacral ligaments may catch and constrict the retroflexed fundus uteri and thus cause congestion of the uterus. As a matter of fact, I may point out that in the post-mortem specimen described by Dr. Williams there was evidence of constriction, but the evidence of congestion having been produced by this constriction is wholly presumptive. Dr. Herman appears to assume that congestion does not occur in the cases of retroflexion except under such circumstances. I have sought for evidence of this last occurrence, and do not for a moment deny that such an effect may be produced, but careful observation has convinced me that it is by no means a common event. A constriction of this kind would be capable of detection by a careful digital examination. Dr. Herman uses this as an argument against the possibility of acute congestion of a retroflexed uterus except in the manner above mentioned. This generalisation is, I feel certain, inaccurate, and does not in the least accord with my own clinically observed facts. He states that I have admitted the greater liability to congestion in retroflexion than in anteflexion cases. Quite true. But I also stated that severe congestion may occur in cases of anteflexion, and I wish here to insist on the point that severe congestion is very common in cases of anteflexion. But to continue the argument. Dr. Herman asks for an explanation of the greater congestion (I deny the greater frequency) in retroflexion cases. My idea is that it is due to the circumstance that the uterus may be more bent in the backward than the forward direction, as a rule at least, owing to Douglas's pouch allowing frequently of easy and considerable descent of the fundus in that direction, while the bladder offers a certain resistance to a great descent of the fundus anteriorly. Dr. Herman gives us the result of his post-mortem examination as to the anatomy of the utero-sacral ligaments. These results I do not undervalue, but I consider the information as to the shape, size, &c., of the back of the uterus in actual cases of retroflexion obtained by examination during life also valuable, and possibly even more valuable. I have tested the matter in this way, and I have failed to find confirmatory evidence of compression by the utero-sacral ligaments to any marked degree associated with acute congestion. Supposing, however, for the sake of argument, we admit that tight utero-sacral ligaments may increase uterine congestion in retroflexion, the same explanation would not be worth much in accounting for the occurrence of acute congestion in anteflexion. The congestion in anteflexion, as also in retroflexion, is, as I believe, largely connected with the shape of the uterus, and the clinical facts show that it is a mechanical congestion. The marked swelling of the posterior lip in retroflexion, the marked swelling of the anterior lip in cases of anteflexion, are some easily recognisable proofs of the truth of this.

There is a further point. Admitting the utero-sacral ligament theory, the flexion still plays an important part; for if the uterus were not retroflexed, it could not be caught by those ligaments or compressed in this particular way, at all events. So far as my experience goes, simple retroversion is unattended with acute congestion of the uterus. Thus the flexion would still constitute an essential factor, and one of great importance in cases of retroflexion *plus* congestion.

Dr. Herman finds cases of retroversion attended with suffering, relieved by pessaries. This is also my experience. But I have never stated that the uterus must be flexed in order to give rise to symptoms. The "position" of the uterus is, of course, the cause of the symptoms in cases of retroversion; and whether they are due to the pressure of the organ on the nerves, on the floor of the pelvis, or on the rectum, or on the utero-sacral ligaments, or some other cause, may be an open question. I should not attempt to apply the notion of strangulation of the vessels of the uterus to such a case, though in Dr. Herman's remarks he imputes to me such an attempt. In speaking of Dr. Herman's use of the utero-sacral ligament theory, I alluded to "congestion" of the uterus and the mechanism of such congestion in retroflexion cases, and no reference was made to "retroversion."

Although Dr. Herman thinks lightly of anteflexion of the uterus, that is not my view of the subject. I have seen numerous cases in which an obstinate acute anteflexion has proved a source of the greatest discomfort and suffering extending over many years, and occasioning an incapacity of various kinds as great as anything observed in severe cases of retroflexion. And the opinion formed as to these cases has been justified by the efficacy of treatment directed to the removal of the flexion or preventing the habitual exaggeration of such flexion on movement by well-arranged support of the fundus by means of a cradle pessary. Dr. Herman's statement as to his experience of the effects of the cradle pessary very widely differs from my own. When the uterus is hard and rigid, this pessary is, no doubt, incapable at the moment of its application of unbending the uterus, and in such cases the uterus must be straightened otherwise. But even repeated straightening of the uterus will have no permanent effect unless the fundus be supported continuously by a pessary such as this; while in other cases where the uterine tissues are not so rigid the pessary alone will, as I have found to be the case in my practice during the last ten years in very numerous instances, reduce the displacement and relieve the symptoms. I may remark that so recently as four years ago Dr. Herman published cases in which he had employed the cradle pessary, apparently with great success in some cases of anteversion. One fails to understand why this instrument should, if so very good for anteversion, be so entirely useless for anteflexion. As regards any difficulty in recognising *bonâ-fide* cases of anteflexion, there is none. The cases are common enough, especially in the middle classes of society; a careful double examination will always give a conclusive means of diagnosis. Anteflexion of a large uterus, even to the degree of a sort of impaction behind the symphysis, is now and then observable, the body of the uterus being with some difficulty pushed upwards. Anteflexion is by some authorities considered a normal condition of the uterus. But those who reject anteflexion as an abnormality inform us that as the bladder becomes filled the uterus rises up, and the uterus falling or rising according as the bladder is empty or full. This is possibly to some extent true. How are we, then, to regard cases when the fundus is constantly found low down behind the symphysis and the uterus much flexed and capable of being pushed upwards only by exercise of force? These cases cannot be considered normal, for in them assuredly there is no movement of restitution accompanying the varying condition of the bladder. These are the cases concerning which more requires to be known, and their clinical features more carefully considered, than has as yet been done. On the question as to retention of coagula and fluids in utero, due to flexion of the uterus, Dr. Herman urges that no sufficient evidence is adducible post mortem to show that the uterine cavity is increased in size in conjunction with flexions, and that drawings representing such dilatation are misleading. I would remark that careful double examination of the uterus during life, together with use of the sound, has convinced me that such dilatation is present in

many cases. It is not difficult in some instances to become convinced of this by the mere use of the sound, the point of which can be made to move freely while the uterus as a whole is quiescent. This pouched condition of the uterus is most marked in some cases of retroflexion, but is not by any means limited to retroflexion. Dr. Herman denies the escape of gushes of fluid from the uterus. I can only say that I took the greatest care to investigate this point a few years ago, and that I found repeated well-marked instances of "leucorrhœa with gushes," in which the only explanation was the accumulation of fluid in utero, due, as I considered, to the pouched state of the organ; a view of the case which was further substantiated by the cessation of the gushes on straightening the uterus. I think Dr. Herman is hardly correct in concluding that fluid may be retained in the vagina in ordinary cases in any quantity, unless the patient be in bed, while there is no such difficulty in supposing that gas might be retained in the vagina. Then, again, as to gushes of blood and coagula being expelled from the uterus in cases of flexion, the reality of such events is not to be questioned, and I have known them to occur in very many instances, about which there could not be the smallest doubt. A frequent sequence of events is: passage of coagula during menstruation; escape of gushes of blood, followed by a sanious, then puriform, leucorrhœa, the latter also coming away in gushes, gradually ceasing in the course of a week or two; repetition of the phenomena next menstrual period.

Dr. Herman's criticisms on my analysis of Vedeler's statistics on the subject of dysmenorrhœa must now be alluded to. He says that I have mixed up versions and flexions together. My object was not precisely to differentiate the two, but rather to follow Vedeler's own attempt—viz., the determination of the validity of the obstructive theory of dysmenorrhœa, including influence of flexions and versions. Dr. Herman points out a slight error I have made, which, however, tells against my own argument. In the next place, he admits that I have shown an error in Vedeler's method of reasoning on the general bearing of his cases, and considers my arrangement of Vedeler's figures forms stronger presumptive evidence in favour of the production of dysmenorrhœa by flexion of the uterus than anything that has yet been brought forward, the result being the conclusion that "decided flexions" were 7 per cent. more frequent in dysmenorrhœa than in non-dysmenorrhœal nulliparæ. Dr. Herman lessens this percentage of decided flexion by subtracting retroflexion to first degree, which still leaves a difference of 6 per cent. In his own series of cases he appears to have found the preponderance of flexion cases with dysmenorrhœa less than that observed in Vedeler's.

One of the chief objections Dr. Herman offers to the flexion-obstruction theory of dysmenorrhœa is the large percentage of cases in which the flexions are present without dysmenorrhœa. As bearing on the explanation of this the statistics of Dr. Emmet are very interesting. He, in speaking of anteflexions, makes a decided distinction between "flexures of the cervix" and "flexures of the body" of the uterus, and gives results of his observations. "When a flexure is found above the vaginal junction there is always pain during the flow, and a state of obstruction does exist beyond question; but with a flexure at the vaginal junction, caused by the neck being too long and thin to remain straight in the vagina, the angle at which it is bent is always more acute than it is with flexure in the uterine body. Notwithstanding this fact, and although the woman will probably be sterile, she does not necessarily suffer from painful menstruation."[1] His statistics show that in all the "unmarried," and in the greater part of the "sterile," anteflexures of the body of the uterus there was pain before or during menstruation. If these observations be correct, and there can be no reason to doubt their accuracy, they would, in part, explain the apparent anomaly of the uterus being much bent while dysmenorrhœa is absent. Another objection of Dr. Herman's is the alleged presence of pain in cases where the uterine canal is found to be straight or patent on use of the sound; and where, further, no blood followed the withdrawal of the instrument (in Schultze's and Burton's cases). Regarding the cases in question, they prove that there was no obstruction to the passage of blood, but there may have been clots or menstrual débris in the uterus, nevertheless, which the uterus was endeavouring to expel, and which were therefore the cause of the pain. Further, it is quite possible that when the examination was made the canal had become dilated by previous expulsive force. I have in general terms expressed my opinion that although not always dependent on flexion of the uterus, by any means, I have found dysmenorrhœa associated with this condition very frequently. In the last edition of my work I stated: "The condition [in dysmenorrhœa] is probably not always the same. In some cases there is present softness, flaccidity, and pouching of the uterus; here straightening from outlet for escape of fluid and the excitation of reflex contraction in the fundus by reflex action (Reil and Champneys) are beneficial. In some cases, again, there is a contraction and condensation of the tissues about the internal os uteri, due to flexion, perhaps, of some standing, and the dilatation and straightening of the canal relieve this, accomplishing the object by actual stretching of the condensed tissues" (p. 490). Of course there are some cases in which the dysmenorrhœa is ovarian in origin, and a few in which stenosis of the cervix is congenital. But the larger number seems to be cases in which dilatation of the cervical canal proves very efficacious in removing the dysmenorrhœa. It is certainly reasonable to associate the efficacy of dilatation in relieving dysmenorrhœa with the increased patency of the canal obtained by its means. It straightens the canal, which effect is only temporary, as is alleged by Dr. Herman; it also increases the diameter, and it remodels, so to speak, the canal as a whole, getting rid of contractions and indurations in its walls, and leaving the canal free for a time, at all events, from flattening such as is present in flexions. It is reasonable to suppose that it tends on the whole to secure a greater "circularity" of the canal than existed before. And on the supposition that the shape of the canal associated with flexion is a bad one, and is a cause of dysmenorrhœa, it is easy to understand that dilatation should be a good remedy for the disease, inasmuch as it will tend to alter that shape, and to recast the canal in a better form, and so ensure a greater patency. With reference to Dr. Herman's own statistics, the remarks I made in my former paper were not intended to throw any doubt on his accuracy of observation. I made a statement to the effect that the uterus sometimes undergoes a change in shape during menstruation, becoming sometimes less flexed at that time than at others. The converse is also sometimes observed to occur. I still consider this an important generalisation, and that it may affect, and ought to affect, the value of statistics on the subject of the frequency and importance of flexions. As to the statement having a "bewildering" effect, I do not think that this is an argument, for facts are facts, after all, and have to be dealt with, however perplexing their import at first view.

In the foregoing remarks I have limited the consideration chiefly to the arguments as regards the importance of alterations of shape and displacements of the uterus based on statistics, on considerations as to the phenomena of congestion of the uterus, and on the statistics and facts relating to dysmenorrhœa. There are many other phenomena relative to the uterus which, when examined clinically, give important evidence as to the disturbing influence of flexions of the uterus, such as unusual sensitiveness of the canal of the uterus, particularly at the internal os, the effect of flexions in producing sterility, primary and secondary, tendency to abortions, &c., and the large and important class of symptoms which are included under the term "hystero-neuroses." I have elsewhere recorded much clinical evidence bearing on these questions, and cannot enlarge upon them in this place.

In conclusion, if it be asserted that many women do not suffer who are the subjects of flexions, it is certain that women who do suffer and who also are affected with flexions become very decidedly relieved when the treatment, general or local, is in effect such as to lessen the degree of the flexion, and in many cases it is enough that the treatment prevents further aggravation of the flexion. Flexion implies a displacement as well as bending of the uterus, and to straighten the uterus is to remove the bend as well as often to replace the uterus. It is remarkable that the measures employed by some of those who deny the importance of flexions of the uterus should be more or less calculated to unbend the uterus; at all events, whether pessaries be employed, or whether the forcible dilatation of the uterus by bougies be put in requisition, the flexion is thereby diminished. This effect is disclaimed, and it is affirmed that these procedures are not beneficial so far as

[1] Emmet, second edition, p. 182.

they depend on the unbending of the uterus. All that can be said is that they are curiously adapted to produce the effect which it is urged is so unnecessary. Nothing will convince me, at all events, that the straightening of a severely flexed uterus is a useless procedure, for the reason that I have found this procedure, accomplished in a variety of ways in different cases, so invariably productive of relief to the patient, and so remarkably efficient in removing the congestion which so frequently accompanies the flexion in painful trouble-some cases. I am not unaware of the occasional difficulty in determining the precise therapeutic value of a particular procedure, and allowances must of course be made and sources of error in this respect guarded against. Dr. Herman thinks I have wrongly attributed benefit derived by my patients to treatment of the flexion of the uterus present in such cases, whereas that benefit was due to the general treatment pursued. I am not likely, as will be gathered from my writings, to undervalue the benefit of careful general treatment. It is just possible that I, having seen and watched these cases, may be a competent judge on this point. Cases are not very rare in which there has been a long trial of general treatment, most carefully adapted to the patient, with entire failure in procuring relief, while an immediate improvement has followed the adoption of local treatment. There is much to be learnt from the endeavour to relieve the suffering attendant on long-standing severe flexion of the uterus. One of the things I have learnt from some experience of such cases is that these cases cannot be cured without a judicious combination of general and local treatment, as I have fully stated on former occasions. But the real truth as to the flexion factor and its importance becomes evident in those cases where good general treatment doing its best for the patient, the difficulty in restoring the uterus to its normal state is unusually great. Then it is seen that the improvement is measured by the success of the local treatment, and that in proportion as the uterus is restored to its proper physical condition, the sufferings of the patient diminish.

Berkeley-square, W.

CASE OF

LARYNGEAL AND PULMONARY TUBERCULOSIS, ORIGINATING IN SIMPLE CHRONIC LARYNGITIS.

BY G. HUNTER MACKENZIE, M.D.,
SURGEON FOR THROAT DISEASES TO THE EYE, EAR, AND THROAT INFIRMARY OF EDINBURGH.

THIS case is thought worthy of record for the following reasons: 1. The priority in origin of the laryngeal as compared with the pulmonary affection. 2. The engrafting of a tubercular on an initial simple inflammation of the larynx. 3. The presence of the tubercle bacillus in the sputum and laryngeal secretion, and its aid in diagnosis and prognosis. 4. Certain toxic effects following the use of iodoform.

The patient, a male aged fifty-five, was first seen by me on March 28th, 1882. He complained of loss of voice, great pain in the ears, especially the left ear, inability to swallow properly, and cough. His throat affection had lasted for about seven years, and was supposed to have been due to a cold from sleeping under an open window. Hoarseness came on at that time, from which he had never been able to free himself, and which finally merged into aphonia. Family history was good. The man's previous history was uneventful, with the exception of a slight cardiac affection of rheumatic origin some twenty years previously. He was tolerably healthy in appearance, of the rheumatic diathesis, with no indication of constitutional disturbance. On laryngoscopic examination, the arytenoid cartilages were swollen (not the typical pyriform swelling of phthisis), the ventricular bands and general mucous membrane of the larynx were irregularly thickened, and the vocal cords could not be seen. Some ashy-white secretion coated the central third of each ventricular band. Faucial sensitiveness was unexaggerated. The pulmonary symptoms were prolonged expiration, a slightly impaired percussion note, and a dry bronchitic click at the end of inspiration at the right apex anteriorly. The sputum was purulent, with a slight admixture of mucus, and contained the bacilli of tubercle in fair abundance in every field of the microscope. The patient was treated by local applications of chloride of zinc and subsequently of nitrate of silver to the larynx, with at first considerable benefit to the laryngeal appearances and symptoms and to his general condition, for from being confined to the house he was soon able to go out of doors. The main indications for treatment seemed to be to endeavour to subdue the local affection by metallic astringents, but a return of pain in the throat, and especially in the ear, compelled an attempt to alleviate the local conditions by sedative sprays, inhalations, and insufflations. Sprays and inhalations proving comparatively ineffectual, recourse was had to an insufflation of morphia, at first alone, but subsequently combined with iodoform; these appeared to produce more benefit than any other local application. The course of the case tended gradually downwards. The laryngeal appearances and symptoms approximated more and more towards the tubercular, and signs of excavation at the right apex were detected towards the end of August. In January crepitant râles were abundantly present down the anterior surface of the right lung, with cavernous breathing at its apex. The pain in the throat and ear was occasionally very severe, especially on swallowing. The patient died on the 15th of February, 1884, of exhaustion from inanition.

A post-mortem examination of the throat only was permitted. There was considerable destruction of the tissues within the larynx. The arytenoid cartilages had undergone necrosis and dislocation, the mucous membrane in their vicinity was swollen and infiltrated, and the ventricular bands had disappeared from ulceration. The vocal cords were intact, except at their arytenoid attachments, where a loss of substance to the extent of one-sixth had taken place. The general mucous lining of the larynx was irregularly thickened, and at the posterior parts of the ventricles on both sides were deep excavating ulcers, leading to the necrosed arytenoid cartilages. Bacilli of tubercle were found in the following situations: (1) In a scraping of mucus from the lower part of thyroid and upper part of the cricoid cartilages. Here they were few, with an aggregation of about twenty in one field. There was no subjacent ulceration. (2) Underneath the anterior commissure of the vocal cords they were about as numerous as in the first situation. (3) In the secretion filling the laryngeal ulcers leading to the necrosed arytenoid cartilages they were from three to four times more abundant than in the other situations. Microscopical examination of sections from the region of the ventricular bands failed to show the presence of tubercle bacilli in the tissues.

As stated in the introduction, the features in the case worthy of notice are as follows:—

1. *The priority in origin of the laryngeal over the pulmonary affections.*—The history of the case undoubtedly points towards the larynx as being the part first affected. The commencement of a sore-throat, with hoarseness, could be traced to one particular evening when the patient, having placed himself in a draught, caught cold. He had hitherto enjoyed good health, and had no predisposition to tubercular disease. He was also assured by a medical practitioner whom he consulted about two years subsequently, in consequence of the persistent hoarseness, that his lungs were quite normal. The whole history and evidence pointed towards laryngitis, of a slow insidious form, as the starting-point of the disease. The examination on my first visit to the patient showed the laryngeal to be much more severe, and apparently of longer duration, than the pulmonary affection. A simple chronic inflammation of the larynx was undoubtedly the first link in the chain which led to such disastrous results to the patient.

2. *The engrafting of a tubercular on an initial simple inflammation of the larynx.*—It may reasonably be inferred that, not only at the commencement of the disease, but for some years subsequently, the condition present was one of simple inflammation of the larynx. Tuberculosis of the larynx lasting for seven years, and without being accompanied by extensive pulmonary changes, is, it is believed, quite unknown. In the present case a persistent chronic inflammation of the larynx disorganised and weakened the organ, and rendered it a suitable nidus for the reception and development of the tubercle bacilli, which readily reached it by inhalation. A progressive chronic inflammation appears to subserve this purpose more effectually than an acute inflammation, even where the latter leaves unmistakable traces of its presence in the form of permanent laryngeal changes. A case has been under constant observation during the last four years in which an acute laryngitis, at one time threatening suffocation, has played considerable havoc with the structures

and integrity of the larynx, but without evincing any tendency towards tuberculisation. On the other hand, several cases, mostly in men, have been noted where, as in the present instance, a slow, gradually progressive inflammation of the larynx has undoubtedly ushered in tubercular disease both of the larynx and lungs. It is impossible to state with precision when the simple inflammation merges into the tubercular unless careful microscopical examination of the sputa be made from time to time with a view to the detection of the bacillus of tubercle. This is undoubtedly the variety of laryngeal tuberculosis in which the laryngeal precedes and leads to the pulmonary deposit, and may therefore justly be called primary laryngeal tuberculosis.

3. *The presence of the tubercle bacillus in the sputum and laryngeal secretion, and its value as an aid in diagnosis and prognosis.*—Of the laryngoscopic appearances in the case the utmost that could be stated was that they indicated a severe form of chronic laryngitis. The chest symptoms showed a bronchitic condition, with probably slight consolidation at right apex. The temperature chart afforded small indication, for the average of fifty observations was, morning 98·2°, evening 98·6°. The discovery of the bacillus in the sputum supplemented in a most material way the other signs and symptoms, and afforded undeniable evidence that the case was of a more unfavourable character than was at first apparent. From March 28th, 1883, till the date of death (Feb. 15th, 1884), the sputum was examined on seventeen occasions, at about regular intervals, for the bacillus of tubercle, with the following results. On each occasion but one they were readily detected. In fair abundance in every field at first, their numbers afterwards seemed slightly to diminish, and in several fields they were not detected. They again slightly increased, and on Aug. 12th a very few were found in the laryngeal secretion on its removal by a brush. On Sept. 22nd, on testing the mucous and purulent portions of the same sputum, they were found from two to three times more abundant in the mucous than in the purulent portion. On Dec. 15th, after a hæmorrhage to the extent of one or two mouthfuls, marked signs of disease at both pulmonary apices, especially the right, and infiltration of the base of the right lung, they were present to the number of from fifteen to twenty in the field, rather isolated, but occasionally two lay in contact in a V-shaped arrangement, or three or four together, but not in contact. On January 16th, after steady persistent treatment by iodoform insufflation and inunction to the extent of inducing iodoform intoxication, the sputum, muco-purulent in character, contained as many as from forty to fifty in the field, generally not in contact. On Jan. 19th, under a continuance of the iodoform treatment, they could not be detected in the sputum, this being the only occasion when such was the case, but when the examination was repeated five days afterwards they were readily detected. It was probable, therefore, that some error in the preparation of the sputum interfered with their detection on the 19th. On Feb. 4th they were again found in the laryngeal secretion to the extent of fifteen in one field. The bacillary history of the case may therefore be shortly summarised by stating that these organisms assisted materially in the diagnosis, that they steadily persisted in the sputum, despite constant treatment by metallic astringents, antiseptic sprays, and iodoform insufflations to the larynx, and that their presence was not accompanied by febrile or other constitutional disturbance. Treatment by iodoform was pushed as far as was considered judicious, but without effecting any reduction in the number of the bacilli, although it diminished the putrefactive odour of the sputum. It is worthy of particular notice that on post-mortem examination, not only were they found in the secretion of the laryngeal ulcerations, but also in the mucus coating the crico-thyroid area, without subjacent ulceration. In the region of the ventricular bands and in the ventricles of the larynx, where they were from three to four times more abundant than in the crico-thyroid region, their presence was associated with deep destructive ulceration. This diversity may have been partly owing to the ventricles of the larynx affording a more secure nidus to these organisms, but probably partly also to the fact that the inferior regions of the larynx and the trachea are lined by a mucous membrane which is closely applied to the inner surfaces of the tube, and whose deeper layers (submucosa) contain strong bands of elastic longitudinal fibres. Whilst, in my experience, it is not uncommon to find erosion of the epithelium in the trachea and lower division of the larynx in phthisis, one can never detect the same destruction as in the neighbourhood of the ventricular bands and arytenoid cartilages. The cartilaginous framework of the larynx and trachea has a resistant power which the softer tissues do not possess, and though, as would appear from the present case, the bacilli of tubercle cling to the whole of the respiratory tube, it is only in the softer tissues of the larynx and in the delicate alveoli of the lungs that their presence leads to deep destruction of tissue.

4. *Certain toxic effects following the use of iodoform.*—This drug was applied by insufflation and by inunction over the larynx and in the axilla. The difficulty in swallowing hindered its administration by the stomach. The formulæ used were, for insufflation, from one to five grains of iodoform with one-sixth to half a grain of acetate of morphia twice daily, and for inunction one part of iodoform to seven parts vaseline, also twice daily. When the larger doses of iodoform were reached, the patient became violent and quarrelsome, and a condition of excitement closely resembling the first stage of alcoholic intoxication was induced, which subsided on the discontinuance of the remedy. Considerable benefit to the local symptoms was experienced at the same time, but though the remedy was pushed as far as was conducive to safety, it was found that no effect was produced upon the bacilli of tubercle, which continued still to be found readily in the sputum. Inunction without insufflation also produced slight excitement and confusion of ideas. In a previous communication to a contemporary[1] I had already directed attention to the toxic action of the drug, and though the views then expressed by me did not find favour with certain continental authorities,[2] further experience has confirmed me as to their correctness. Dr. Batty Tuke, who saw the case now under notice with me, has informed me that, soon after seeing my patient, he was called to another case, in which the free use of iodoform produced the same symptoms as those above described, which disappeared on the discontinuance of the use of the drug. M. Maitre[3] considers that, taken by man in doses of from five to six grains, it causes no notable symptoms; but my experience is that a smaller dose may readily induce toxic symptoms, particularly in weakly individuals.

With regard to the action of this remedy in laryngeal tuberculosis, although probably by its anæsthetic action it has a soothing effect on the throat, it does not seem to have any effect upon the disease. It does not diminish the number of bacilli in the laryngeal secretions, nor does it appear to promote the healing of the laryngeal ulcers. Little effect can, however, be expected from any remedies in such cases, unless use be made of them at very early periods of the disease, for its later stages are characterised by such an amount of laryngeal destruction and constitutional deterioration as invariably leads to a fatal termination.

Edinburgh.

A CASE OF LITHOTOMY WHERE THE NUCLEUS OF A LARGE PHOSPHATIC CALCULUS WAS THE WHALEBONE MOUTH-PIECE OF A TOBACCO-PIPE.

WITH REMARKS.

BY REGINALD HARRISON, F.R.C.S.,
SURGEON TO THE LIVERPOOL ROYAL INFIRMARY.

APART from the general interest attached to cases of this kind, which, curiously enough, are not very uncommon, there are, in this instance, two points upon each of which a few remarks may be made.

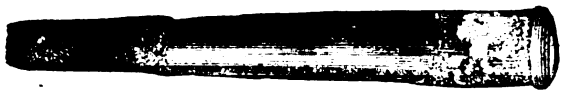
Robert H——, aged thirty-three, a seaman, was admitted on June 23rd, 1884, into the Liverpool Royal Infirmary suffering from symptoms of vesical irritation. The history elicited the following points:—Eight years previously the patient had gonorrhœa, from which he recovered quickly. In December last he had some scalding after micturition, and on the 13th of the same month he was admitted into a hospital in Wales with a fracture of the leg. Whilst in hospital he appears to have suffered from vesical irritation and passed two pieces of calculus; his symptoms continued

[1] Edinburgh Medical Journal, January, 1883.
[2] Centralblatt für klinische Medicin, 1883, No. 11.
[3] Wood's Treatise on Therapeutics, p. 384. See also British and Foreign Medico-Chirurgical Review, vol. xxxiv., p. 247.

on his return home to the Isle of Man. On admission into the Liverpool Infirmary I found him suffering from calculus in the bladder. Upon examining the calculus with the lithotrite it proved to be large, soft, and peculiarly shaped. The last-mentioned circumstance made me resolve to cut instead of to crush.

On June 27th I performed lateral lithotomy, and removed a large phosphatic calculus, which broke under the grasp of the forceps, and disclosed the whalebone mouthpiece of a tobacco pipe, to which a small piece of rotten string was attached. It was noticed that the smell of tobacco in the mouthpiece was quite distinct. As the phosphatic envelope crumbled under the pressure of extraction, it was impossible to estimate correctly its weight. It must have been very large. About an ounce of these fragments was collected. The exact size of the mouthpiece is shown in the drawing. The patient made a good recovery, and left the infirmary on July 28th.

On the fourth day after the operation I showed him the foreign body, and asked whether he could offer any explanation as to how it got into his bladder. He remarked that "he was glad to see it again. He had swallowed it whilst playing with some companions on board ship three years ago. He felt no pain at the time, nor until last December, when the symptoms of stone became manifest." He was frequently spoken to in reference to the improbability of such an explanation, but he would never admit of any other construction being placed upon the word "swallowed" than that usually adopted. In this statement of the patient will be found the first point of interest. Though so highly improbable, was it possible? The only case I know of which would at all substantiate the idea that a foreign body of this nature could find its way into the bladder from the intestines is one recorded by Sir Alfred Roberts, of the Sydney Hospital, who removed by



lithotomy a piece of slate pencil two and a quarter inches long, which it was alleged had been swallowed. Commenting on this case, the author says: "I have left no stone unturned to elucidate the truth in this very interesting case, and can only state that after much hesitation I have arrived at the conclusion that the pencil was swallowed by mouth and made its way by inflammation and ulceration into the bladder."[1]

The second point of interest is in reference to the circumstances generally which determine us in the selection of lithotomy or lithotrity. These can never be regarded in the light of hard-and-fast rules. In this instance, in the absence of all history, I had every reason to believe that I had to deal with a calculus which, though large, was still, by reason of its softness, quite within the limits of crushing. Had such an operation been attempted, the splitting of the nucleus into fragments would almost certainly have been attended with a fatal result. In this instance the peculiar shape of the calculus rendered me suspicious that I had something unusual to deal with; further, there was a consciousness that there was not that easy access, with the open jaws of the lithotrite, to all parts of the calculus, which is an important feature when crushing has to be undertaken. On these points I mainly relied in deciding in favour of lithotomy, a choice which was more than vindicated by the very unexpected discovery that was subsequently made. In a case previously reported,[2] where I extracted a pencil-case three and a half inches long from the male bladder with the lithotrite, the patient came under my notice within a few hours of the alleged introduction, by other persons, of this article up his urethra, and before sufficient time had elapsed to permit of the deposition of phosphates upon it.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The Library of the College will be closed on Friday (this day) till Monday, the 16th inst., for the purposes of the Hunterian Oration and Festival. The Oration will be delivered in the theatre by Prof. John Marshall, F.R.S., LL.D., on Saturday, the 14th inst., at three o'clock precisely.

CASE OF REMARKABLY SLOW PULSE WITH EPILEPTIFORM SEIZURES; AUTOPSY.

BY A. T. GIBBINGS, M.D. LOND.

THE following case, read in connexion with one reported by Mr. St. George Mivart, in THE LANCET of Jan. 3rd, seems to me of sufficient interest to be put on record.

J. B——, aged sixty-six, a tall spare man, with well-marked arcus senilis, had pleurisy as a young man, and presents the marks of cupping for the attack; he says that his pulse has been very frequently intermittent ever since he can remember; has worked rather hard at his office, and has had a good deal of anxiety and worry in domestic matters. There is no family history of any neurosis. He has never had syphilis, gout, or rheumatism, and has been strictly temperate. He consulted me in May, 1882, for weakness and difficulty of breathing, especially on exertion. He complained also of attacks of dyspnœa at night, lasting sometimes for a few minutes, sometimes for an hour or so; also of a troublesome noisy cough. Urine normal; heart and lung sounds normal; pulse intermittent, about 60. He attended more or less regularly for some two months, improving considerably under treatment, though not altogether losing his dyspnœa. From Oct. 21st to Nov. 21st he was confined to the house with an attack of bronchitis, attacks of dyspnœa occurring irregularly, chiefly at night. He returned to business on Nov. 21st, and attendance was discontinued until Dec. 2nd, when I was again sent for. I was struck by the slowness of his pulse, which was 44, and quite regular. He was ordered a mixture of arsenic and strychnia. He went in a cab to business, but had frequent feelings of faintness, for which he was obliged to resort to alcohol or ammonia. On January 3rd, 1883, he was seen in consultation with Sir Andrew Clark, having become steadily worse. He now complained of dyspnœa on the least exertion, and of frequent feelings of faintness. His pulse was now 34, regular and synchronous with the heart beats. Walking up and down the room did not increase the frequency of the heart beats. Sir Andrew Clark recommended that he should be kept in the recumbent position, be fed every three hours, and have six ounces of port or burgundy in the twenty-four hours. He continued to take considerable quantities of nourishing food, which he digested well. Notwithstanding this, the sensations of faintness became very frequent, the pulse steadily declined in frequency, and now a new symptom showed itself. This consisted in frequent epileptiform attacks. The face became deadly pale, the pupils dilated, and the eyes fixed; the pulse ceased to be felt at the wrist. After a few seconds it returned feebly; the face then flushed all over, and clonic convulsive tremors lasted for five or six seconds. The first indication of an attack was the non-recurrence of the usual pulse beat. Almost directly there was a moaning sound, and the face became pale and fixed. This sequence was observed repeatedly, so that with the finger on the pulse I knew that an attack was beginning a second or two before the face changed. He had generally an aura, consisting of a feeling of hot fluid at the back of the neck. On Jan. 20th he was seen in consultation with Dr. Moxon, when his pulse was 22, full and regular, his heart beats corresponding in time. Dr. Moxon could find no evidence of disease of the heart or lungs. The brain was active and clear, and there were no nervous symptoms. Dr. Moxon recommended a trial of nitro-glycerine and atropia. Matters did not mend at all. The epileptiform attacks became very frequent and distressing; rising in bed would generally bring them on, but they also occurred when at absolute rest in the recumbent posture. On the 26th Dr. Moxon again saw the patient, and it was agreed to try bromide of potassium in thirty grain doses, with the hope of checking the fits, which were now most distressing. This he took for two days, but became decidedly worse. The pulse fell to 13, then to 12 on January 28th. The nurse's journal says on the morning of the 28th, "Free from attacks for one hour during the night, all the rest of the night he passed from one fit into another." A considerable amount of albumen was found in the urine. I now decided to discontinue all medicine. He began again slowly to improve, and gradually by February 26th the pulse had reached 31; the albumen had soon cleared away. After this he got up every day and worked two or three hours at

his account books. He felt altogether better, but there was dyspnœa on exertion. He continued to take nourishment well, the pulse keeping over 30, and varying from that to 33 or 34. On March 6th, while at stool, he fainted, and died in two or three minutes. The temperature, taken occasionally, the last time on February 21st, varied between 96·6° and 97·4°. It never reached 98°. The respirations varied from 18 to 24. It should have been stated that the heart's apex was in the normal position, the impulse was normal, and the heart sounds distinct and without murmur. The infrequency of the beats was owing to prolongation of the diastole.

Autopsy.—Dr. Moxon, Dr. J. W. Hunt, and myself were present. The right pleura contained about one pint of serous fluid. Beyond that the appearances were almost entirely negative. The valves and muscular walls of the heart were healthy, the coronary arteries being pervious. The arteries generally were remarkably free from atheroma. The liver, kidneys, brain, and medulla oblongata were to all appearance normal.

Remarks.—Two questions suggest themselves in connexion with this case—1st, what was the cause of the gradual slowing of the pulse? 2ndly, what was the cause of the epileptiform seizures? The latter were evidently caused by sudden anæmia of the brain. The absence of the recurring pulse beat was always the first in order of the phenomena of the seizures. An intermission of the heart-beat when the pulse is only sixteen or twenty must cause a temporary deficiency of blood in the cerebral vessels. The patient, even in health, had very frequently suffered from intermittent pulse. The cause of the former is more obscure. Post-mortem examination gave nothing but negative indications, while Dr. Moxon's well known skill and experience in this department is a guarantee that no gross change was overlooked. I think there can be little doubt that we must look to the nervous mechanism regulating the heart's action as the factor in its causation. Physiology teaches that stimulation of the vagus will produce this inhibitory or slowing action. Czermak, as is well known, was able at will to stop the beating of his heart, by pressing his vagus against a small osseous tumour in his neck, and thus mechanically stimulating the nerve. In Professor Foster's "Physiology" it is stated that "stimulation of the vagus produces in the ventricle simple lengthening of the diastole without change in the force of the systole." But there is another way in which this retardation may be brought about, and that is by the bringing into abeyance the action of the intrinsic cardiac ganglia, the normal inhibitory action of the vagus being then unopposed. To quote Professor Foster again:—"If a ligature be drawn tightly round the junction of the sinus venosus with the auricles, or if the auricles be separated by an incision carried along the boundary line between the two, a standstill is produced closely resembling a very prolonged vagus inhibition." Probably, then, the cause of the gradual slowing of the pulse must be sought either in an irritative lesion of the vagus or in a degenerative lesion of the cardiac ganglia. Nothing at present is known of changes in these ganglia. The pleuritic effusion no doubt occurred during the last two or three weeks of life, when, finding the patient dressed at the time of my visits, I did not continue to make careful examinations of his chest, as I had done previously at frequent intervals.

Richmond-road, Dalston, E.

ARTIFICIAL CIRCULATION AS A MEANS OF RESUSCITATION AFTER APPARENT DEATH.

BY CHAS. EGERTON JENNINGS, F.R.C.S.ENG.,
ASSISTANT-SURGEON TO THE CANCER HOSPITAL, ASSISTANT-SURGEON TO THE NORTH-WEST LONDON HOSPITAL.

CHLOROFORM POISONING.

(*Concluded from p. 247.*)

Experiment 8.—July 29th, 2 P.M.: One grain of morphia was injected into a terrier weighing 14·38 lb. The administration of chloroform was commenced at 3.34 P.M. When the animal was anæsthetised, a ligature was passed through the tongue. It was noticed that firm traction on this organ did not satisfactorily withdraw the epiglottis, which can be readily seen in the dog. A ligature of fine silk was passed through the epiglottis by means of a small curved needle, so that traction could be made on the epiglottis directly. Respiration stopped at 3.46 P.M. The pulse stopped at 3.51 P.M. The right external jugular vein was now exposed, and the cannula inserted. Depletion showed that the blood was not nearly of so dark a colour as that drawn in the previous experiments; doubtless owing to the access of air to the lungs afforded by traction on the epiglottis. Altogether 20 oz. of saline fluid (temp. 90° F.) with ten minims of liquor ammoniæ were injected. Artificial respiration was continued, and normal respiration returned at 4.2 P.M., the circulation being re-established first; in fact, very shortly after the saline injection was commenced. The blood lost by depletion was partly caught in a porcelain dish, but a considerable quantity escaped beneath the dog, and some also ran through perforated holes on the table to a shelf below. The experiment was therefore carried further than was necessary to restore animation, and afterwards, when the quantity of blood lost, which was in excess of the saline liquid injected, was examined, it was clear that sufficient had not been left within the vessels to maintain life for more than a short period. This experiment was performed by Dr. Boddaert and myself. At 6 P.M. it was reported by one of the laboratory porters that the dog had been "dead" for some time, probably for about fifteen minutes. The body was quite warm, but respiration and circulation had certainly ceased, and the forelegs were stiff. Half a minim of liquor ammoniæ with twenty minims of water were injected directly into the left ventricle through the chest-wall, and the injection was immediately followed by a return of pulsation. The tongue was drawn out of the mouth, and the epiglottis grasped with artery forceps. The laboratory porters were directed to perform artificial respiration whilst I prepared a saline solution. On exposing the left external jugular vein, that vessel was found much collapsed; twelve ounces and three drachms of saline fluid were injected. (Transfusion of blood was strongly indicated here, for the animal was dying from hæmorrhage, and the blood in the body was already very much diluted. Nevertheless it seemed better to inject saline fluid instead, and to watch

the result, rather than complicate the experiment further.) The hind-legs of the animal were bandaged firmly and elevated, in order to drive the blood towards the vital centres. At 6.30 P.M. the dog was placed before a stove, and half a drachm of brandy with an equal quantity of water, and $\frac{1}{15}$ of a grain of atropia were injected subcutaneously. At 7 P.M. the pulse was 96, and six deep inspirations were taken per minute. The dog died at 10 P.M. The autopsy made the following day showed that the left ventricle was firmly contracted. Not much blood was found in the vessels, and it was entirely fluid. There was a small extravasation (caused by the point of the syringe) beneath the visceral pericardium. Death evidently occurred from paucity of blood, and a comparison of this experiment with Experiment 15 fully justifies the opinion that had transfusion of blood been performed prior to 10 P.M. on the previous evening, life would have been saved.

Experiment 9.—To determine whether the intravenous injection of fluid (with simultaneous depletion) performed shortly after apparent death excites the heart to pulsation by stimulating the organ itself—either the intrinsic ganglia of the heart or its muscle fibres—or by stimulating certain ganglion cells in the medulla. July 30th, 2.30 P.M.: One grain of morphia was injected subcutaneously into a dog weighing 11 lb. At 3 P.M. chloroform was administered, the tongue and epiglottis were drawn forwards, and a cannula was inserted into the right external jugular vein towards the heart. The animal was then destroyed by pithing the medulla, and immediately afterwards saline fluid (with half a minim of liquor ammoniæ to each ounce) was injected into the vein, simultaneous depletion being practised, and artificial respiration being maintained. Altogether about 40 oz. of ammoniated saline fluid (temperature 90° F.) were infused, and three minims of liquor ammoniæ were injected by means of the syringe. The heart continued to beat till most of the blood had been expelled from the body. Inspection of the heart and vessels showed that they were filled with saline fluid tinged with blood. The experiment was unsatisfactory in this respect, that after the medulla was destroyed observation was not made as to whether the heart actually stopped. So that it cannot be asserted that the circulation was re-established by the infusion and depletion, but it can be said that, by the procedure, the circulation was well maintained. It is a physiological fact that after destruction of the medulla the heart's action does not instantly cease. But I do not think that in this experiment the circulation would have been maintained so long or so strongly without the saline injection. There was no violent action of the heart after the injection of the ammoniated fluid such as has been noted in some of the preceding experiments. Therefore this experiment indicates that, after apparent death, the infusion of a saline ammoniated fluid accompanied by depletion, if it produce reanimation at all, acts in a twofold manner—(1) by directly stimulating the heart—whether its muscle fibres only, its intrinsic ganglia, or both, are distinct questions; and (2) by stimulating certain ganglion cells in the medulla.

Experiment 10.—Infusion with depletion for chloroform poisoning. July 30th, 2.30 P.M.: One grain of morphia was injected subcutaneously into a dog of 15·2 lb. weight. 4.10 P.M.: Chloroform administered. The tongue and epiglottis were drawn forwards. Pulse 105 per minute. The anæsthetic was given freely with plenty of air. 4.24 P.M.: The respiration stopped. 4.27 P.M.: The pulse stopped. 4.32 P.M.: Infusion and depletion were commenced, and artificial respiration was performed. Altogether nearly 40 oz. of saline fluid (with a quarter of a minim of liquor ammoniæ to each ounce) were injected. Two minims of liquor ammoniæ were also injected by the syringe, and subsequently half a minim of liquor ammoniæ with a little water was injected directly into the left ventricle. No signs whatever of reanimation occurred. Some of the fluid was injected into the left common carotid artery, after the injection into the jugular vein had failed.

Autopsy.—The vessels and heart were moderately filled with blood and fluid. The ventricles were dilated.

Observations.—(1) The blood in this experiment was very thoroughly impregnated with chloroform; (2) the infusion and depletion were not commenced till five minutes after the pulse, and eight minutes after the respiration had failed; (3) only half the quantity of liquor ammoniæ had been employed in the saline fluid, as compared with that used in the other experiments.

Experiment 11.—August 1st, 10 A.M.: One grain of morphia was injected into a dog of 11·12 lb. weight. At 10.21 A.M. chloroform was administered, and the tongue and epiglottis were drawn forwards. 10.30 A.M: The pulse became intermittent. 10.34 A.M.: The pulse stopped entirely, and the respiration directly afterwards. After an interval of less than a minute the operation was commenced. Depletion and injection with artificial respiration were performed as in the other experiments. The pulse returned at 10.43 A.M.—i.e., after a cessation of nine minutes. Normal respiration recommenced at 10.47 A.M. At 11.7 A.M. the pulse was 52, and the respiration was 40 per minute. Altogether nine ounces of saline fluid, at 100° F. (with three-quarters of a minim of liquor ammoniæ to each ounce) had been infused, and one minim of liquor ammoniæ had been injected by the syringe. The depletion was considerably less than the infusion, for after the experiment the dog weighed 11·38 lb., and had therefore gained more than a quarter of a pound in weight. This animal recovered perfectly.

Experiment 12.—August 1st, 11.40 A.M.: One grain of morphia was injected subcutaneously into a dog weighing 7·05 lb. 11.58 A.M.: Chloroform was administered. The tongue and epiglottis were drawn forwards. 12.3 P.M: The pulse became intermittent. At 12.5 P.M. the pulse and respiration stopped; but returned after the performance of artificial respiration. Chloroform exhibited again. At 12.8 P.M. the pulse and respiration ceased, and did not return after the renewal of artificial respiration. Depletion, with injection of saline fluid into the external jugular vein, was made at 12.9 P.M. The pulse returned at 12.11 P.M., and normal respiration thirty seconds later. At 12.45 P.M. the pulse was 76, and the respiration was 60 per minute. This animal recovered. The quantity of saline fluid infused was nine ounces, and contained three-quarters of a minim of liquor ammoniæ to each ounce. One minim of liquor ammoniæ was also injected by the syringe. The infusion was in excess of the depletion, for after the experiment the dog weighed 7·35 lb.—i.e., it had gained about a third of a pound by the experiment.

Remarks.—The preceding experiments show that if depletion and intravenous injection be performed quickly after apparent death (i.e., before coagulation of the blood has commenced—and it commences early in cases of chloroform poisoning), pulsation will be restored. Experiment 2 has demonstrated, also, that if chloroform poisoning occur where the blood is in a diluted and *fluid* condition (and fluidity can always be attained by the exhibition of ammonia, as proved by Dr. Richardson), pulsation may be restored some minutes after apparent death by the operation. The only reasonable explanation of these phenomena is that the "vital centres" do not necessarily perish with the cessation of pulse and respiration; and if the circulation and respiration can be restored—a thing always possible, provided the blood be fluid,—the vital centres will often resume their functions, even after they have been suspended for a period of some duration. It was resolved to repeat the last experiment, allowing a lengthy interval to elapse after apparent death before attempting to restore the circulation; and in subsequent experiments to exhibit ammonia before the administration of chloroform, that the blood might be kept fluid after the signs of animation had departed.

Experiment 13.—Aug. 1st, 3 P.M.: Half a grain of morphia was injected into a dog of 9·8 lb. weight. Chloroform was administered at 3.49 P.M. The pulse became intermittent at 3.54 P.M.; it stopped completely once or twice, but was restored by artificial respiration. Finally, the pulse and respiration ceased at 4.2 P.M. The injection and depletion were commenced at 4.4 30 sec. or 4.5 P.M. In the interim M. Nuel kindly made an ophthalmoscopic examination, and afterwards wrote for me the following note:—"La choroïde était tout à fait exsangue. Les petits vaisseaux rétiniens n'étaient pas visibles (ils étaient vides). Mais les gros vaisseaux rétiniens renfermaient du sang; seulement les colonnes sanguines étaient interrompues à la périphérie de la papille." Altogether 30 oz. of saline fluid (containing 22 minims of liquor ammoniæ) were infused, and two minims of liquor ammoniæ were injected by the syringe. This was about three minutes after signs of life had disappeared. The blood which flowed from the vein was partly coagulated, and very dark in colour. No return of pulsation occurred.

Experiment 14.—August 4th, 9.40 A.M.: One grain of morphia was injected into a dog of 16·21 lb. weight. At 9.55 A.M. the pulse was 83 per minute. 9.57 A.M.: Hypodermic injection of three minims of liquor ammoniæ in a little water. 10.5 A.M.: Pulse 56 per minute. 10.10 A.M.: Injection of ammonia repeated. 10.30 A.M.: Pulse 50 per

minute. 10.39 A.M.: Chloroform was administered. 10.46 A.M: Irregularity of the pulse. 10.47 A.M.: The pulse stopped. 10.47 30 sec. A.M.: Respiration stopped. 10.49 30 sec. A.M.: Injection and depletion commenced; artificial respiration was performed, with the tongue and epiglottis drawn forwards. 10.56 A.M.: Pulse returned. 10.58 A.M.: Normal respiration returned. At 11.20 A.M. the pulse was 40 and the respiration 14 per minute. Thirteen and a half ounces of saline fluid at 96° F. (with three-quarters of a minim of liquor ammoniæ to each ounce) were infused. One minim of liquor ammoniæ was injected by the syringe. After the experiment the dog was found to have gained about ·15 lb., therefore the infusion was in excess of the depletion. The animal recovered.

Experiment 15.—Aug. 4th, 11.33 A.M.: One grain of morphia was injected subcutaneously into a dog of 27·09 lb. weight. 11.37 A.M.: Hypodermic injection of six minims of liquor ammoniæ in water. 11.49 A.M.: Administration of chloroform. The epiglottis and tongue were drawn forwards. 11.53 A.M.: The pulse became intermittent. 11.56 A.M.: The pulse stopped. 11.58 A.M.: The respiration ceased. 12.4 P.M.: Injection and depletion, with artificial respiration. 12.5 20 sec. P.M.: Pulse returned. (Therefore pulsation was absent during a period of 9 min. 20 sec.) 12.5 35 sec. P.M.: Normal respiration was established. At 12.35 P.M. the pulse was 36 and the respiration 20 per minute. Nearly 9 oz. of saline fluid were infused, with three-quarters of a minim of liquor ammoniæ to the ounce (temperature 96° F.). Ammonia was not injected by the syringe. After the experiment the dog weighed 25·77 lb.—i.e., it had lost 1·32 lb. The excessive loss of blood was due to two circumstances—first, considerably more blood flowed during the operation than was intended, and, secondly, hæmorrhage occurred from the jugular vein after the infusion and depletion, owing to the slipping of a ligature. From the figures which have been given it will be seen that though the dog had recovered from the toxic effect of the chloroform, yet its life was jeopardised by the quantity of blood which had been lost. In such a case as this nothing but transfusion of blood would prevent death (cf. Experiment 8). However, there was no immediate danger, and the operation of transfusion was therefore postponed till that time had elapsed which, in actual practice, would be required to obtain a blood-giver. In the afternoon a large quantity of blood with a little saline fluid—for the blood of the animal was already much diluted—was transfused into the left femoral vein. Ether and a little chloroform were employed for the receiver, and chloroform was administered to the giver during the operation. Ammonia was not added to the saline fluid, because the blood of the receiver was already highly ammoniated. After the transfusion, saline fluid was infused into the giver.

Giver, weight 30·39 lb.:—	Receiver, weight 25·77 lb.:—
3.15 P.M.: Hypodermic injection — morphia, 2 grs.; atropia, $\frac{1}{75}$ gr.	4 P.M.: Pulse 36 per minute; shivering. After the transfusion of blood and saline fluid the animal weighed exactly 27·09 lb., which was its original weight.
4 P.M.: Transfusion, followed by repletion with saline fluid. Weight after experiment 29·84 lb.; therefore loss = ·55 lb.	

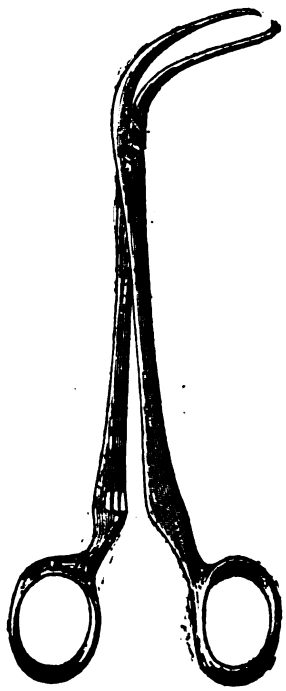
During the experiment 24 oz. 5 drs. of saline fluid (temperature 85° F.) were employed. Both animals recovered.

Experiment 16.—August 5th, 10 A.M.: A grain and a half of morphia was injected into a dog of 26·32 lb. weight. Six minims of liquor ammoniæ, in a little water, were also injected subcutaneously. 10.40 A.M.: Administration of chloroform. 10.50 A.M.: The pulse became intermittent. 10.50 30 sec. A.M.: The respiration ceased. (The tongue and epiglottis had fallen back, and were now both drawn forwards. Artificial respiration was performed till 10.58 A.M.) The pulse stopped at 10.55 A.M. 11.4 A.M.: Depletion and injection of saline fluid at 100° F. (with three-quarters of a minim of liquor ammoniæ to the ounce) into the right external jugular vein. There being no response to the injection—performed nine minutes after the cessation of the pulse,—the cannula was removed, and inserted into the left carotid artery (towards the heart) in order to inject the coronary arteries. No response. The cannula was then removed, and reinserted towards the cerebrum (11.34 A.M.), when muscular movements over the face and neck occurred. No other signs of animation.

Experiment 17.—Aug. 5th, 11.45 A.M.: A dog weighing 21·8 lb. Half a grain of morphia and five minims of liquor ammoniæ in water were injected subcutaneously. 12.9 P.M.: Administration of chloroform. 12.13 P.M.: Respiration stopped. 12.14 15 sec. P.M.: Pulse stopped. 12.22 P.M.: Injection of ammoniated saline fluid into the carotid artery, towards the cerebrum. Simultaneous depletion from the external jugular vein. Muscular twitchings over the face occurred. The jaws were closed, the eyelids were opened and shut, but no other signs of animation were observed.

Remarks.—All surgeons are aware that death from the administration of chloroform occurs either by asphyxia or by "paralysis of the heart." If death take place from asphyxia, the asphyxia is almost always an epiphenomenon. The tongue falls back, the laryngeal musculature is paralysed, the epiglottis drops over the superior aperture of the larynx. If the tongue be drawn forwards, and artificial respiration be now performed, a little air will enter the lungs, but not very much, for the epiglottis is flaccid, and at each inspiratory movement of the chest is drawn down like a valve. If the tongue be drawn out of the mouth forcibly with artery forceps, as advocated in Holmes's "System of Surgery" by Sir Joseph Lister, more air will enter the larynx, around the tip and edges of the epiglottis; but the access of air to the lungs is by no means free. This can be readily demonstrated on the dead body, if a vertical section be made of the head and neck; and the foregoing experiments have conclusively proved the accuracy of this statement. If, therefore, life be threatened by asphyxia during anæsthesia, and any impediment be noticed to the entrance of air to the lungs during artificial respiration, either tracheotomy should be performed or the epiglottis should be drawn forwards with forceps. On dogs the latter object can be easily effected with common artery forceps. Owing to the different configuration of the parts in man as contrasted with the dog, I have had forceps for the epiglottis made, which, as will be seen from Fig. 3, follow Sir Spencer Wells's forceps with regard to the handle, and artery forceps in respect to the point. Mr. Marshall has informed me that in one case he performed tracheotomy with success, for asphyxia consequent on anæsthesia; and the sudden rush of air into the trachea demonstrated the necessity for the operation. A similar rush of air is noticed when the epiglottis is drawn forwards under like circumstances, and the only superiority of tracheotomy over traction on the epiglottis is that it is perhaps more speedy, and a freer access of air would be gained to the lungs because the sectional area of the opening made in the trachea would be greater than that of the rima glottidis. The arguments to be adduced in favour of the choice of traction on the epiglottis are that by direct experiment the method has been proved successful, and that by it tracheotomy can be avoided. If death be imminent during chloroform anæsthesia from "paralysis of the heart"—true chloroform poisoning—when, as a rule, the circulation ceases before the respiration,—the maintenance of an artificial circulation is clearly the right line of treatment. Experiment 5 shows that if this plan be adopted within 2 min 40 sec. after apparent death, life can be saved. Further, if ammonia be exhibited prior to the administration of chloroform, life may be saved, as shown by Experiment 15, if the injection be made within eight minutes after cessation of the pulse, and six minutes after cessation of the respiration. Clearly, the practical point is to give a full dose of sal volatile before commencing the administration of chloroform, in order that, should an accident occur, time may be gained. The greatest danger exists when the patient, from dread of the anæsthetic, struggles and holds the breath for some seconds or

FIG. 3.



more, till the blood is carbonised, and then takes a few short, deep inspirations. Only too often a small but concentrated quantity of the vapour suddenly enters the lungs, and the pulse and respiration abruptly stop. Attention having been first paid to the access of air to the lungs, the external jugular vein should be instantly exposed and grasped in the lower angle of the wound with Wells's forceps. The vein can now be opened on the cephalic side of the forceps, so that artificial respiration can be performed without the risk of admitting air to the vein. The experiments embolden me to state that if this method be adopted promptly, reanimation would almost certainly follow the venesection. If the circulation be not re-established at once, the only remaining chance of safety would lie in the infusion of saline fluid, with or without the cautious use of ammonia. Since the dread of anæsthesia can always be prevented by the subcutaneous injection of morphia, it is difficult to understand why that alkaloid is not employed more frequently than it is, in a full dose, before the administration of chloroform. Atropia might be most advantageously combined with the morphia, since physiology teaches that atropia prevents inhibition of the heart through the vagus.

"Artificial circulation" having been treated by previous writers, I desire particularly to refer the reader to Dr. B. W. Richardson's paper on "Restoring the Life of Warm-blooded Animals,"[1] to a paper by the same author on "Death from Chloroform,"[2] and to Dr. Ringer's communication concerning the "Effects of Dilution and Concentration on the Action of Poisons."[3] And since the research which forms the basis of the present communication has been conducted apart from preconceived ideas, the opinions deduced therefrom will be found in some respects to confirm, and in others to antagonise, the views of the distinguished men who have already worked at the subject.

Park-street, W.

BULLET WOUND OF LUNG.

By C. B. MAITLAND,
OF HER MAJESTY'S BOMBAY MEDICAL SERVICE.

AT the present time, when pulmonary surgery is attracting a good deal of attention, the following case may be interesting as showing how comparatively slight the constitutional disturbance may be consequent on a severe injury to the lung.

On Sept. 7th, 1884, Heera, a low caste Hindoo aged sixty, in the habit of eating and drinking anything he could get, was admitted into the Staff Hospital, Deesa, with a recent rifle-shot wound of the chest. The rifle, a Snider, had been fired 150 yards to his front. The entrance was between the second and third ribs, two inches from the right edge of the sternum; the ribs were uninjured. There was no exit wound, but the fourth and fifth ribs on the same side were broken midway between the scapula and the spine, apparently a piece of each rib being knocked out. There was considerable shock, but scarcely any bleeding, so a little rum was administered. For ten days the man remained fairly comfortable, the tongue, at first furred, cleaning, and only occasionally coughing up a little rusty sputum. On the twelfth day his temperature was 99·5°, and on examination behind I found a swelling, fluctuating with the respiration, opposite the sixth interspace, in the same vertical line as the break in the ribs. On opening this, a somewhat flattened Snider bullet was extracted—it was lying outside the chest cavity—and about a pint and a half of offensive blood-stained pus let out. For three weeks the lung cavity was washed out daily with carbolic solution (1 in 40), the fluid latterly returning nearly clear. The patient all this time suffered from no inconvenience, except when being injected the syringe hurt the broken ends of the ribs. Air passed freely through the posterior wound when uncovered, and once a slough two inches long came away. The morning temperature was always normal, the evening temperature ranging from 99° to 99·5°; respiration averaged 40, and pulse 96. On Oct. 11th his temperature went up to 100°, so a drainage-tube was inserted in the sixth interspace without making a fresh wound, and some offensive pus let out. Next morning the temperature and pulse were normal, and the respiration 32. In a week the injected fluid returned clear, and in a month the tube was finally removed. Now, Dec. 17th, the man is apparently in perfect health, fatter than before the injury, and the lung performing its functions. His recovery will seem the more remarkable to those acquainted with the prematurely aged and shrivelled appearance of indigent Hindoos.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas at morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Prœmium.

ST. MARY'S HOSPITAL.

STRICTURE OF THE URETHRA CURED BY EXTERNAL URETHROTOMY; SUBSEQUENT DEVELOPMENT OF EPITHELIOMA OF THE BLADDER AND GENERAL DISSEMINATION OF THE GROWTH; DEATH; NECROPSY; REMARKS.

(Under the care of Mr. A. J. NORTON.)

THE patient, a plumber, aged fifty-five, was admitted in March, 1884, suffering from impassable stricture of the urethra, apparently the result of a blow on the perineum received eighteen years before. No catheter larger than a No. 4 could be passed at the end of a month; the operation of external urethrotomy was then performed, and the patient left cured in the early part of June. At that time there was no evidence of malignant disease, though on one occasion the urine contained albumen and blood. He was readmitted on the 27th of October; and to better comprehend the sequence of the symptoms the post-mortem record of the case is first given. Lungs adherent to the diaphragm, and infiltrated with cancer. Abdomen: Intestines adhering together, mesentery infiltrated with cancer, peritoneum thickened generally with cancer. Peritoneal coat of intestines contained nodules of growth; main growth nearly as large as a cocoa-nut, connected with the summit of the bladder, spreading in an irregular nodulated mass around the rectum and lower part of the sigmoid flexure, which latter was bent in the growth at two acute angles, so as to produce total obstruction. The ureter and left external iliac vessels traversed the growth, but were not compressed. A section of the growth was soft and creamy-looking in parts, almost purulent, and in parts traversed by dense fibrous tissue. Lymphatic glands behind the bladder in the pelvis and the abdominal glands all generally affected. On opening the bladder an epithelioma not of large size, perhaps an inch and a half square, occupied the summit, and the mucous membrane of the bladder was remarkably thick, thrown into coarse folds and quite white in colour, but not infiltrated with cancer. In the urethra there was no sign of the former stricture, but in its place where urethrotomy had been performed was a conical dilatation with the apex towards the skin.

On his readmission at the above date, he was in a feeble state, unable to walk with any vigour, was pale, and seemed in pain. He said he had no irritability of the bladder, but his urine was red, containing a considerable quantity of blood, an enormous quantity of mucus, some albumen, and quantities of triple phosphate crystals. There was pain over the region of the bladder, and when the abdomen was examined there was found a mass in the left iliac fossa fixed firmly along the brim of the true pelvis, quite immovable, and extending back to the sacrum; it seemed to be raised about one inch from the bone, and was quite hard. Examined by the rectum nothing important was found. The prostate was normal, and as high as the finger could reach no growth could be detected. The excessive quantity of mucus suggested severe catarrh, but a tumour of the bladder could not with certainty be diagnosed. (It may be here mentioned, to show the subsequent rapidity of the growth, that the bowels were normally open.) Constitutionally the patient was ill; certainly the pulse was full and steady (71 per minute), and he slept well; but the tongue was thickly coated, the appetite impaired; he was pale and restless when awake. The

urine was ordered to be drawn off and the bladder to be washed out with a solution of Condy's fluid daily, using a soft catheter; and it was found on passing a No. 10 catheter that there was no return of the former disease, stricture. The patient, of course, remained in bed, taking milk diet only, and on Nov. 9th he stated that he was much more comfortable; the mucus in the urine had considerably diminished, and there was only a small staining of blood; the tongue was clean, and the pulse 72; the bowels comfortably open.

On Nov. 13th the notes suggest that the patient was rapidly improving, for the pain was subsiding. He expressed himself as greatly relieved. Tongue clean, temperature normal, and but little blood in the urine. This apparent improvement can only be referred to his complete rest in bed.

On the 15th, Mr. Norton's fourth visit, he found the patient complaining of great pain, aching and lancinating, in both loins and over the pubes; the pelvic growth had very distinctly increased in size, and the glands along left Poupart's ligament were enlarged. The bowels were still open normally. Temperature normal; pulse 76; but he could not sleep and his appetite was failing. He had literally no irritability of the bladder, never requiring to pass urine oftener than when in a state of health; it contained a large quantity of blood and mucus. A catheter was passed, and, after drawing off the urine, it was moved a little freely in the bladder, which bled rapidly. Examination by rectum disclosed no tumour within reach of the finger, but there was a gland behind the bladder enlarged to the size of a cob-nut but quite movable. It was concluded that there was a tumour of the bladder, which bled freely when touched, and which was the cause of the condition of the mucous membrane, and it was clear that the tumour was carcinomatous, and that the pelvic mass was secondary growth. From this time the disease made rapid progress; the tumour had increased visibly at each examination, twice a week; the bowels became confined; he suffered from tympanites and spasmodic or cramping pains in the upper abdomen, and from aching and lancinating pain in the pelvic region; the pulse was 90; the blood increased in quantity in the urine, and was of a florid-red colour; and the patient got no rest at night except under the influence of opium.

On the 19th the temperature rose to 101°; and on Dec. 4th he was jaundiced, and for a week previously the bowels had not been opened except by large enemata. The pulse was now 100, the temperature ranging between 100° and 102°. He was refusing food, and each day becoming sensibly weaker, the tongue brown and dry, and the breath fetid. On Dec. 9th he died.

Remarks by Mr. NORTON.—At my first visit there was no blood in the specimen of urine shown to me, but a very great quantity of mucus, and at the visit I recognised the presence of the growth at the brim of the pelvis. The mucus was evidence of severe catarrh, and I looked upon this as the result of a former stricture and of a dilated bladder unable to expel all its contents. I therefore made him pass his water, and then inserted a soft catheter to see if any were retained; but I found the bladder empty, a proof that there was no paralysis, a very common cause of catarrh, and one the presence or absence of which one should never fail to ascertain by the method I have mentioned in every case of catarrh of the bladder that comes under notice. The tumour in the pelvis I did not like to pass an opinion upon at my first visit; I thought it to be malignant, because he complained of pain, and manipulation did not cause the pain to arise at the moment of examination, and because the tumour was intensely hard and immovably adherent. At my third and fourth visits there was blood in quantity in the urine, and this blood was of a florid colour, evidently derived from a bleeding surface, and not smoky, as it appears when arising from passive congestion or a diseased condition of the kidneys. Now the blood came in quantity with the last four drops of urine. I therefore passed a metal catheter to sound the bladder, and found that hæmorrhage was produced by moving the instrument within the bladder. I had now no hesitation in asserting that the bleeding was from a growth in the bladder, and that the tumour in the pelvis was secondary deposit or in connexion with it. I say in connexion with it for this reason, that notwithstanding the condition of the urine there was absolutely no irritability of the bladder. He passed urine only three or four times a day, from which I inferred that the tumour was not situated near the neck, but at a distance from that region, probably near the summit of the bladder, and that the tumour was not large so as to be compressed when the bladder was empty, otherwise there would have been pain and irritability of the bladder. I now examined per rectum, and could not feel within the length of my finger any definitely marked growth. Now, if the tumour were at the summit of the bladder, as it turned out to be, it would be closed up to the region where the secondary growth, or extension of the same, was situated—namely, at the brim of the pelvis. We had now clearly diagnosed the case, and as it was malignant disease, there was no possibility of operative interference. We had, therefore, only to watch the case and treat or relieve symptoms. We had to give the patient rest by means of soporifics, and to relieve pain by anodyne injections into the bladder, and later on to overcome the obstruction in the bowels by laxatives and enemata.

LEITH HOSPITAL.

COMPOUND DEPRESSED FRACTURE OF THE SKULL; EXUDATION OF CEREBRAL MATTER; RECOVERY.

(Under the care of Dr. FINLAY.)

FOR the following notes we are indebted to Mr. C. Stein:—

The two cases of compound depressed fracture of the skull, each of which was complicated by wound of the brain and loss of cerebral substance, will be found very interesting, whilst the result in each proves the wisdom of the treatment adopted. In neither case do the symptoms appear to have been in anything like proportion to the amount of injury sustained. In the case under Mr. Spofforth's care there were no symptoms beyond those produced at the time of injury; and in the case under the care of Dr. Finlay, beyond twitching of the left hand, noticed seven days after admission, there were no symptoms of importance developed. In neither case was there any paralysis noticed, and in each the recovery appears to have been perfect.

J. S——, a boy eleven years of age, was brought to Leith Hospital on October 7th, 1884, at 4.30 P.M., his head having been crushed between the edge of the pavement and the wheel of a lorry. He was semi-comatose, though struggling and screaming, and had vomited freely. There was a scalp wound one-third of an inch long, situated an inch below the right parietal eminence, and the surrounding portion of the scalp was much bruised and swollen. Lying in the wound was a slight speck of a whitish substance resembling brain matter. Blood was oozing freely from the wound. On examining the skull, there was found an extensive depressed fracture involving a considerable portion of the right side of the skull. The pupils were equal. A light dressing was applied to the wound, and the boy was put to bed, where cold was applied to his head by means of an ice-bag. During the night he remained more or les unconscious, and was exceedingly restless.

Next morning (Oct. 8th), Dr. Finlay considered it advisable to examine the fracture more thoroughly. During the administration of chloroform the boy struggled considerably, and fully a tablespoonful of brain matter escaped from the wound. The wound was enlarged upwards and downwards, and an extensive V-shaped fracture was found extending downwards and backwards from the original wound. The apex of the fragment of bone was depressed to the extent of the thickness of the skull. Owing to the great extent of the fracture, Dr. Finlay considered any operative interference unwarrantable, and accordingly the wound was dressed with glycerine of carbolic acid and salicylic wool. During the course of the day the patient gradually became more conscious, but towards night he was again very restless and complained of pain in his head. After a hypodermic injection of morphia he fell asleep.

The patient continued to improve steadily, and by Oct. 18th he ceased to complain of pain in his head, was able to sit up in bed, and took his food well. The wound was at first dressed every two days, and afterwards at longer intervals, and was entirely healed by Oct. 27th.

On Nov. 7th the patient was allowed to leave his bed.

On the 24th he was discharged from the hospital. During the whole course of his illness his temperature only once reached 100° F., which occurred on the morning of the fourth day after the accident (Oct. 11th), while on the evening of the same day his temperature was 98·4°.

On Oct. 14th there was perceptible occasionally a slight twitching of the left hand.

On Dec. 5th the patient came to the out-patient room

with his father, who stated that he was as intelligent and active as before the accident, and quite able to go on with his school work. On examining the skull, there was to be felt a distinct depression about one inch long, and large enough to allow the end of the little finger to lie in it, situated nearly one inch below the parietal eminence, just at the position of the original wound. The boy was quite bright and intelligent, and there was no loss of power or sensibility in any part of the body, neither were any morbid sensations present.

KIDDERMINSTER INFIRMARY.

COMPOUND DEPRESSED FRACTURE OF SKULL; EXUDATION OF CEREBRAL MATTER; TREPHINING; RECOVERY; REMARKS.

(Under the care of Mr. SPOFFORTH.)

WE are indebted for the following notes to Mr. Frederic S. Barber, house-surgeon:—

Mary B——, aged twenty-five, was admitted on Nov. 11th, at 1.20 A.M. She was unconscious, much collapsed, and bleeding freely from the scalp. On examination it was found that over the left parietal region there was a large lacerated wound leading down to a depressed fracture of the parietal bone near its anterior inferior angle, the depressed portion being about an inch and a half in length at its free edge, and being driven in to the extent of about one-third of an inch. Behind this, and situated over the posterior inferior angle of the parietal bone (and over the lateral sinus), was an incised wound, leading down to a well-marked fracture of the bone, but with no depression. There was also another scalp wound and continuance of the fracture over the longitudinal sinus above the occipital protuberance. From the history, the above had all been produced by an assault with a hatchet. The wounds were dressed with carbolised oil, and restoratives given to the patient, who remained unconscious till about 5.30 A.M., when she became dreamily aware of her surroundings and able to answer simple questions. In this state she remained till the forenoon, when Mr. Spofforth proceeded to trephine. On removing the dressings, those coming from the anterior wound were found to be smeared with cerebral matter, and a quantity of cerebral matter was noticed beneath the scalp. In elevating the depressed portion (after removing a semicircular pledget), Mr. Spofforth found it necessary to use his whole force. The wound was loosely sewn up with silver, a small drainage-tube introduced beneath the scalp, having two free ends, and dressed with carbolised oiled lint and absorbent wool. The dressing was allowed to remain undisturbed for fifteen days, at which time the wounds were found to be quite healed (with the exception of the orifices for the tubing), perfectly dry, and a marked absence of purulent discharge. The tubing was withdrawn and a fresh dressing applied as before; afterwards it was freely oiled and lightly protected by a bandage. She complained of much pain at first, which was checked by a one-grain opium pill occasionally, and a calomel purge was given, otherwise she received no medicine. Her mental faculties were not impaired, and all her special senses were perfect. She had inability for voluntary micturition for a few days, but that has since become normal. The highest temperature reached was 100·8° on the fifth day and 100·6° on the eighth day, since which time it became quite normal.

Remarks.—We notice the position of the depressed fracture almost over the middle meningeal and of the posterior one over the lateral sinus; then the evidence of the membranes being ruptured and the cerebral matter exuding, and at the same time apparent absence of meningitis; the continued integrity of all the senses; and the rapid repair of the parts, with scarcely any suppuration.

THE Rivers Committee have presented a report to the Manchester City Council in which, after careful consideration of the question of the best method for the treatment and disposal of the sewage of Manchester, it is recommended that they be authorised to make inquiries and report as to the land which can be obtained at a reasonable rate for carrying out either the irrigation or precipitation system, and to report to the Council the result of such inquiries, together with particulars of the scheme to be adopted for the complete interception of the drainage of the city.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Displacement and Fracture of the Axis.—The Radical Cure of Club-foot.

AN ordinary meeting of this Society was held on Tuesday last, Dr. George Johnson, F.R.S., President, in the chair. The following gentlemen were elected Fellows of the Society: Drs. W. D. Halliburton, F. W. Mott, Theodore D. Acland, A. Haig, Messrs. James Berry, John Cahill, W. M. Collins, F. H. Hawkins, K. W. Millican, and J. Poland.

A paper on a case of Displacement and Fracture of the Axis was read by Dr. DAVID LOWSON. The paper was communicated to the Society by Sir Prescott Hewett, Bart. The injury occurred ten years ago to a man aged seventy-five, who fell on the vertex of his skull from a wall six feet high. After recovering consciousness, the patient experienced great pain in the neck. The head was bent back and carried stiffly. Nasal respiration was obstructed, and the mouth kept open to render respiration easier. Deglutition was difficult; the voice had a nasal intonation; and a hard swelling could be seen and felt projecting from the back of the pharynx. There was no paralysis or anæsthesia. The patient died in July, 1884, from a disease having no connexion with the injury. At the post-mortem examination it was found that the axis was bent back to an angle of 60°, the bodies of the second and third vertebræ were ankylosed, and the arch of the third was partially telescoped into that of the second, to which it had become ankylosed. The cord was gently bent opposite the site of the injury, and the spinal canal at this point was quite wide and roomy. The specimen was exhibited to the Society, and also a somewhat similar one from the St. Bartholomew's Hospital Museum. It appeared that Sir James Paget had discovered a specimen of displacement and fracture of the axis in a churchyard, and Sir Prescott Hewett had had two cases similar to the one here recorded.—The PRESIDENT referred to the rarity of this injury, and to the obstruction of the œsophagus caused by the projection of the displaced bodies of the vertebræ.—Mr. ADAMS asked whether any attempt was made to put the neck straight. There need be no fear of doing harm by straightening the neck in cases which were usually partial unilateral dislocations of the neck; symptoms referable to injury of the cervical nerves were generally present. Three cases were briefly related which had been treated by him by immediate extension and complete rest.—Mr. NOBLE SMITH said he had seen one case of this injury, and there was a projection in the region of the second or third cervical vertebra. The patient was placed under chloroform, and the neck was restored to its normal shape without disaster. Reference was made to certain specimens in the museums of the hospitals, showing the conditions resulting from caries of the body of cervical vertebræ.—Dr. LOWSON said, in reply, that his patient suffered but little, and so really required no surgical interference. His case was one of injury, and he had said nothing as to the consequences of disease of the cervical vertebræ.

A paper on the Radical Cure of Club-foot was read by Mr. RICHARD DAVY. The author arranged his subject under the following heads:—1. The line of thought that has induced operative procedures in cases of intractable club-foot. 2. The cases especially suited for operation. 3. The operation itself, the description of its details, and the instruments necessary for its performance. 4. The list of twenty-six cases operated on by the author, and notes of other cases operated on by other surgeons. 5. The exhibition of casts taken before and after operation, and also of living specimens or the results gained. Also six specimens of the blocks of bone removed by the operations. 6. General observations on club-foot, with conclusions. The author considered that his operation was founded on the experiment made on the dead body of freely opening the transverse joint, twisting the foot into varus position, and inserting into the transverse tarsal joint a wedge. This demonstration justified the removal of the cuboid bone on the living subject in 1874, and, in addition, the base of the fifth metatarsal bone in 1875. The instruments and splint used by the author were exhibited, and his method of operating and after-treatment described. The open-air

method of cicatrisation had been practised on all his cases. The mortality of this operation was less than 4 per cent., as only one of the twenty-six cases operated on had died. Nineteen of the cases were boys, and four were girls. Two cases were submitted to the double operation at one sitting. Fourteen were cases of talipes equino-varus, ten were cases of talipes varus, and two were cases of equinus. The oldest patient was twenty years old, the youngest fifteen months. The average stay in the hospital from the date of the operation to that of discharge was seventy-seven days. The results of the operation were most satisfactory. A shortened symmetrical foot is left, which is far preferable to a stump. The patients become plantigrades, dispense with instruments, and perform their ordinary duties. Six specimens of the osseous wedges removed (all in one block of bones), showed as component parts the individual bones of the transverse tarsal joint; one specimen showed portions of the astragalus, os calcis, the bases of four outer metatarsal bones, and the internal cuneiform bones, and the whole of the scaphoid, cuboid, and two outer cuneiform bones. Professor Ogston's operation of attacking the astragalo-scaphoid joint by operation was alluded to in relation to flat-foot, but up to the present the excision of an osseous wedge at the transverse tarsal joint had been restricted to equinus and varus cases or their combinations. Mr. Edward Lund's operation of removal of the astragalus was also mentioned. In conclusion, the author put this excision of an osseous wedge forward as mainly applicable to inveterate cases; he was inclined to plead for its adoption in young persons under certain circumstances. The author summed up in favour of this operation as follows:- In obstinate club-foot, where osseous distortion has occurred, a definite mechanical operation with definite surgical landmarks performed on the tarsal bones has led to definite results; these results, occurring in the experience of one surgeon, may help to obtain general recognition of the value of the operation as a means of remedying deformity.—Mr. W. ADAMS said that the relapse of cases of talipes after tenotomy was largely due to neglect of proper treatment by mechanical appliances after the tendons had been cut. He made certain objections to Mr. Davy's operation, which interfered with the important movements of the transverse tarsal joint, whilst Mr. Lund's operation interfered with the movements of the ankle joint, and left those motions dependent on the transverse tarsal joint.—Mr. R. W. PARKER said that for some time past he had been engaged in the study of the talipedic foot, and in conjunction with Mr. Shattock had embodied his observations in a paper which would be found in the last volume of the Pathological Society's Transactions. In the course of the dissections made for the purposes of the above paper, he had been struck with one or two anatomical points not referred to in books on the subject which appeared to him to have an important bearing on the treatment of these cases. With considerable opportunities he had not seen any cases of talipes in young subjects which had not yielded to very much milder measures than those proposed by Mr. Davy, and he could hardly imagine a case in which such an operation would even be justifiable in an infant of fifteen months. In adults who had been neglected, and in whom, in addition to the primary deformity, there had supervened secondary deformities from walking on the inverted foot, talipes became incurable by the ordinary means; but considering what such patients could do with their deformed feet, how they could and did tramp about, it was questionable whether any operation could do much to improve them, beyond, perhaps, improving the appearance of the foot. If this were all, it was not worth all the risk run, and all the time consumed. In saying this, he was not reflecting on the operation, but expressing his own personal view on the subject generally. In dissecting talipedic feet, he had found, though the astragalus was usually altered in shape, that this was not invariable; on the other hand, in all the cases, the ligaments were shortened, and in severe cases, even after the removal of all the muscles, the foot could not be straightened on account of this shortening of the ligaments. Thus, in one well-marked case, the anterior portion of the internal lateral ligament of the ankle-joint had blended with the talo-scaphoid and the calcaneo-scaphoid ligaments, and formed a strong unyielding capsule about the astragalo-scaphoid joint; this resisted all attempts to straighten the foot; even after this capsule had been divided the foot could not be put quite straight. It was necessary to divide also the capsules of the joints between the scaphoid and the internal cuneiform, and between the cuneiform and the first metatarsal bone. He was thus led to think that in the treatment of talipes more attention should be given to the ligaments than was usually done, and that many of the inveterate cases met with in practice were due to shortening of the ligamentous structures on the inner side of the foot. If the ligaments and muscles were equally stretchable—which was not the case—we should naturally expect more stretching in the muscles than in the ligaments, by reason of their greater length; it indeed appeared strange that so much should be made of the value of stretching and tenotomising structures like the muscles, while the short unyielding ligaments were left to take care of themselves. He exhibited some specimens illustrating this shortening, also another specimen showing that the ligaments could be divided without difficulty and without any damage to other important structures of the foot. He recommended this operation for all severe cases in young persons, and for inveterate cases in the adult before severer measures were adopted, and indicated the method of carrying it out.—Mr. NOBLE SMITH thought that the question raised was as to the comparative merits of osteotomy and the ordinary methods of treating cases of talipes. Much mechanical support was lost when all the tendons were divided at the same time. Osteotomy was no doubt far more serious than any of the other surgical measures usually employed in such cases.—Mr. WALSHAM believed that Mr. Davy's operation could only be required in very rare cases. He had seen but four or five cases which seemed to require division of the transverse tarsal arch. A description was given of the case in which he had performed the operation of removal of a wedge-shaped portion from the tarsus. A simple transverse division of the tarsus was an excellent plan of operation, and in one case this had to be supplemented later on by the removal of a wedge-shaped piece from the cuboid bone. In this case he also performed the operation on the opposite foot; the patient was two and a half years old; the result was decidedly good.—Mr. DAVIES COLLEY had performed the operation of removal of a wedge-shaped portion from the tarsus of the foot for talipes in October, 1875, so that there was an inaccuracy in Mr. Davy's statement that the operation was performed in 1877. He thought that the operation could be done perfectly with the aid of a raspatory and a fine saw, and without the employment of any special instruments.—Mr. JOHN CROFT had performed Mr. Davies Colley's operation four times for talipes varus in children. Tenotomy and mechanical apparatus were certainly insufficient for the cure of many of these cases. In all cases the wound had absolutely healed in three weeks, and if proper antiseptic precautions be adopted ten days were sufficient.—Mr. WILLIAM ROSE had done Mr. Davy's operation in two cases; the boys' ages were fourteen and nine respectively. No orthopædic treatment could have made those patients plantigrades. The results were very satisfactory, and the wounds were treated strictly antiseptically, with the result that healing was very rapid.—Mr. BRODHURST considered that osteotomy was a dangerous and unnecessary measure for any case of congenital varus.—Mr. RICHARD DAVY, in reply, said that in his paper he had credited Mr. Davies Colley as the first to perform the operation. With regard to his method of treating the wounds, he said that Dr. de Forrest Willard had collected statistics of seventy cases, and it came out that the mortality was greater than his (Mr. Davy's) was; so that, unless future experience proved that antiseptics were required, he should continue his mode of treating the wound. Casts were shown of a case on which Mr. Manby had operated. The deformity was of the most marked kind, and could probably only have been relieved, as it was by Mr. Manby, by some such operation as that which he had ventured to bring before the Fellows of the Society. The prolonged course of treatment necessary for such cases was, amongst other reasons, a very powerful argument in favour of further surgical procedure being employed than was usually adopted.

MEDICAL SOCIETY OF LONDON.

Discussion on Renal Surgery.

AN ordinary meeting of this Society was held on Monday last, Mr. Arthur E. Durham, F.R.C.S., President, in the chair.

Mr. HENRY MORRIS read a paper, opening the discussion. He said that certain definite surgical operations, such as nephrotomy, nephro-lithotomy, and nephrectomy were well

recognised as not only justifiable, but successful, in combating certain affections of the kidney. There remained much to be learnt with respect to the symptoms which should guide us as to these proceedings, also as to which of these operations is best adapted for particular cases, and as to how we could most safely and certainly find out the working power of the second kidney, or even if a second kidney existed. Two things were required before a surgical exploration of the kidney were undertaken. First, symptoms must exist which are regarded as characteristic of renal calculus; and, secondly, these symptoms must have shown themselves irremediable by medicinal treatment. These characteristic symptoms were the peculiar pain of renal colic, the presence of blood and pus in the urine not possessing constant characters, the absence of morbid conditions of the bladder and prostate, and frequency of micturition. Without doubt these symptoms were strongly suggestive of calculus, but were not positively characteristic of it. The absence of all symptoms was not, however, conclusive of the absence of calculi. He had in his possession a list of nineteen cases in which nephro-lithotomy had been done. He had also in his possession a list of sixteen cases typically indicative of renal calculus, in which there was complete failure to find the stone after surgical exploration. The lumbar incision was almost without danger to life, and this was a fortunate circumstance. Many morbid conditions existed which simulated stone in the kidney, and not unfrequently nephro-lithotomy relieved such conditions. Excessive mobility of the kidney was one of these conditions, and the relief of symptoms after the performance of a nephro-lithotomy may be readily explained by the fixation of the kidney, resulting from the changes which take place in the inflammatory exudation caused by the surgical interference. In other cases, as Mr. Annandale supposed, the division of some of the nerves in the neighbourhood of the kidney caused the cessation of the pain. We have analogous cases of relief of symptoms in the results of neurotomy, neurectomy, and nerve stretchings, and in those cases in which epileptic seizures have ceased after division of the scalp and after trephining healthy cranial bone. The lumbar incision may relieve the tension of cases of chronic perinephritis, just as happens in cases of periostitis after incision, and in cases of ostitis after drilling the bone. In a fourth set of cases in which intense pain is complained of, and a history of hæmaturia is given, the whole of the symptoms may be due to hysteria. An abnormally acid urine, or urine highly lithatic, may cause all the symptoms of a renal calculus. Again, though no calculus has been formed, a number of crystalline forms or calculous particles may simulate renal calculus. In a certain number of cases slight and early scrofulous disease of the kidney has been mistaken for a calculus, and relief has followed acupuncture or incision. A calculus may be present and yet escape detection, either because of the great toughness and thickness of the renal tissue, or because the stone has become displaced from the kidney and impacted in some part of the ureter. It is hardly likely that such cases would be relieved by surgical exploration. There is a great resemblance between the symptoms of stone and those of acid urine. In these cases the gouty diathesis may exist, and, though no actual pain is suffered, testicular tenderness is present. The value of alkaline treatment in such cases is paramount. Hæmaturia is looked upon almost as a necessary result of calculus. Renal hæmorrhage may occur without very obvious cause, as from congestion or increased blood pressure; and if this should occur in rheumatic, hysterical, or highly neurotic individuals, the symptoms of renal colic may be very closely simulated. When the lumbar or testicular pain is absent, frequency of micturition with pyuria and hæmaturia are insufficient for a correct diagnosis. Should we examine both kidneys from within the abdomen under these circumstances? If there be crystals in the urine and the case be in a bad way, and if digital examination of the vesical ends of the ureters gives a negative result, he thought we should. The differential diagnosis of early strumous disease from renal calculus was not unfrequently one of great difficulty; again, a calculus may be present with strumous disease. We need more accuracy of diagnosis as to the site of a calculus when it is present. Is it in the calyx, pelvis, or ureter? and, if in the ureter, at what part of its course? He had related a case of vesico-urethrotomy for the removal of a calculus from the vesical end of the ureter in the *American Journal of Medical Sciences* for October, 1884. The cases recorded by Drs. Agnew and Rawdon were quoted in illustration of the symptoms caused by impaction of a stone within the ureter. Dr. Cullingworth excised a calculus which had been impacted in the upper end of the ureter. The patient died, and the other kidney was found to be riddled with abscesses and the ureter blocked. The case, nevertheless, gives promise of good results from intra-peritoneal ureterotomy. The following propositions were given:—1. Although hæmaturia, associated with frequency of micturition and a small amount of pus in the urine, is, in the absence of disease in the lower urinary tract, strong evidence in favour of renal calculus, yet that pain either in the loin, groin, or testicle of one side is also needed to justify the surgeon in exploring the kidney through the loin. 2. That pain alone, when persistent or frequently paroxysmal, and giving rise to sickness and sweatings, or subject to exacerbations during perfect rest, justifies lumbar exploration when there is a history of hæmaturia without pus, or a trace of pus without a history of hæmaturia, associated with one-sided pain, the exploration ought to be made if alkaline treatment have failed. 3. That when the above symptoms occur in persons with acid urine, or of gouty tendency, or who lead sedentary or indulgent lives, alkaline treatment ought to have a prolonged trial before an exploratory incision is proposed. 4. That when the urine is alkaline from carbonate of ammonia, and not from fixed alkali, the alkaline treatment should be tried on the ground that urine very acid when secreted irritates and inflames the mucous membrane, and so causes the alkalinity which is found when the urine is discharged from the body. 5. That under certain circumstances an abdominal exploration in search of calculus in one or other or both kidneys is justifiable. 6. That if strumous, not calculous, kidney cause the above symptoms, the lumbar incision may give great relief by affording exit to pent-up pus. 7. That under the circumstances previously stated, digital exploration of the bladder in search of calculus in the ureter ought to be made, and if a stone is found in the vesical orifice it ought to be removed. 8. That removal of the calculus impacted in the ureter by intra-peritoneal ureterotomy is feasible, and in certain cases ought to be practised. 9. That exploration of the kidney should not be considered complete till incision of its substance has allowed of the thorough examination of the calyces, and that nephrectomy ought not to be entertained until after free incision of the kidney and digital exploration of the bladder have failed to disclose the calculus. 10. That exploration of the bladder in the female certainly, and in the male generally, ought to be made before nephrectomy is resorted to for hydronephritic and pyonephritic tumours. 11. A stone in one kidney may sometimes excite sympathetic pain and irritation in the opposite one; the pain is then aching, not spasmodic; the surgeon should, however, explore when pain is severe and frequent. 12. Experience suggests that after lumbar exploration the patient should be kept on his back, and a well-adjusted compress should be placed on the abdomen over the front of the organ explored, as there is, though rarely, a tendency for the kidney to fall away from the loin and delay in the completion of the healing of the wound. The next subject dealt with was as to which of the operations should be resorted to in certain cases, and whether any at all should be performed in others. Differences of opinion may arise as to what has to be done in cases of floating kidneys, wounded kidneys, cancer, strumous disease, and cystic enlargements and distensions of the kidney. Nephrectomy was considered to be not justifiable in cases of floating kidney. With regard to wounded kidneys many circumstances had to be taken into consideration; but if the indications of injured kidney, or pelvis of kidney, are marked and the gravity of the case is urgent, an incision should be made over the kidney at once, and drainage or nephrectomy performed according to circumstances. If primary nephrectomy has not been performed, and prolonged and profuse suppuration occurs, secondary nephrectomy should be practised. Median urethrotomy or lateral prostatotomy should be performed if clots of blood accumulate in the bladder or are forced into the urethra, giving rise to obstruction, pain, and distress. In cancer of the kidney nephrectomy is hardly ever justifiable. Nephrotomy may give relief to or even check the progress of strumous disease. Nephrotomy, followed by antiseptic irrigation and drainage, was still the operation where large abscesses have formed, and where perinephric suppuration has occurred. Nephrectomy must not be performed in cases

of tubercular disease if the system at large is affected. If the disease be limited to one kidney and there is danger of exhaustion from suppuration, nephrectomy may advantageously be performed after nephrotomy has failed. The greatest divergence of opinion has prevailed in cases of hydronephrotic and other cystic tumours of the kidney. Nephrectomy ought rarely, if ever, to be performed unless the tumour is of immense size and nothing but a cyst wall remains. Even then puncture or nephrotomy should have preceded nephrectomy. Hydronephrotic tumours may subside spontaneously; a single tapping, or a repetition of tappings, may cure some cases; nephrectomy has cured others, and some have gone on well for a long time after nephrotomy with a urinary sinus in the loin. Mr. Morris would say of renal cysts generally that as soon as the tumour has reached a size which causes inconvenience by pressure, not to say danger from rupture, it should be tapped, and that if it refill it should be cut down upon, punctured and emptied, and then incised, and the edges of the cyst should be stitched to the edges of the wound. If a fistula remain and prove troublesome, the question of nephrectomy may be considered, and the character of the fluid discharged should decide the question. If the kidney structure be functionally sound, and secretes several ounces of urine per diem, the remains of the organ should not be sacrificed on the ground that a kidney and part of another is much safer than one healthy kidney. Frequency of micturition may have something to do with the causation or increase of a hydronephrotic tumour. The arrangement of the vesical openings of the ureter, and of the muscles concerned in these parts, was demonstrated by diagrams taken from those given by Sir Charles Bell in the third volume of the Royal Medical and Chirurgical Transactions. The frequency of micturition should be controlled if possible, and a most powerful method of doing this was median urethrotomy. If it be performed, the vesical ends of the ureters should be digitally examined to see whether either of them is blocked by an impacted stone. Some reference was made to methods for ascertaining the character of the urine secreted by each kidney, and special mention was made of Tuschmann's instrument. Mr. Morris considered, however, that such plans were probably not likely to be of much value. In ascertaining the existence of a second kidney, instruments for closing the ureters might be more useful; but if allowance be made for cases of congenital malformations of the genito-urinary organs, there is an intrinsic improbability against either congenital absence or atrophy of the kidney. Out of 8068 autopsies there were but two instances of congenital absence, and one of congenital atrophy.

Mr. A. E. DURHAM felt great interest in the subject of the surgery of the kidney, and he said that he had predicted that in the surgery of the future the kidney would come much more into the hands of the surgeon. He believed that he was the first in this country to cut down on a kidney with a view of removing a stone; none was found on examination, though the symptoms were most characteristic. Another case was mentioned in which many calculi were removed, but the kidney was not excised. The patient died of peritonitis, and the evidence at the autopsy fully justified his not excising the kidney.

Mr. BRYANT said that he was chiefly struck by Mr. Morris's remarks on the diagnosis of renal calculi. Surgical interference must always in the first instance be of an exploratory kind.

Dr. TUSCHMANN thought the employment of an instrument for closing one ureter was most necessary in determining the existence of a second kidney.

Mr. KNOWSLEY THORNTON asked whether in the cases in which no stone was found there had been sufficient exploration. With regard to the good effects of fixing the kidney, he considered that then the stone did not move about as it did in the normal kidney, and so the relief of symptoms might be explained. He had found hæmaturia absent in one case of stone of the kidney under his care. Frequency of micturition was perhaps more frequently associated with scrofulous kidney than with calculus in the kidney. He asked whether digital exploration of the bladder was always a safe measure; suppression of urine had occurred in a case in which he had rapidly dilated the urethra. He considered that it could never be justifiable to perform nephrectomy for cancer of the kidney. He had advocated the bringing out of the ureter, and could not agree that to leave the ureter in its natural site was the best method of dealing with it. The danger from intestinal obstruction seemed to him to be infinitesimally small. He had now performed his operation in eleven cases, with success in all; but in the six in which he brought out the ureter the recovery was most rapid.

Mr. CLEMENT LUCAS related a case of strumous pyelitis in which all the symptoms pointed to calculus, but none was found. Exploration in every possible way had failed to detect a stone; later on phthisis developed. More than a year ago he had removed a calculus from the kidney, in which case there were no abnormal signs in the kidney. Mention was made of a case where in removing a kidney from a child the diaphragm was perforated, but the careful use of antiseptic agents and the catgut suture seemed to be followed by the best results, for the patient did not suffer from any symptoms referable to the lung or pleura.

Mr. WALTER PYE spoke of the extraordinary powers of resistance of the kidney to the presence of foreign bodies in its pelvis. Reference was made to the case of a man aged forty-two in whom suppuration existed in and about the kidney, and in which an operation for removal of the kidney was broached though never performed, and the patient, though discharging much pus, was still in good health. He confessed to a certain amount of belief that stones in the kidney would to a large extent look after themselves.

Mr. HENRY MORRIS, in reply, said that of the nineteen cases referred to the kidney was incised in three or four cases. He believed that an irritable bladder was much more frequently associated with scrofulous kidney than renal calculi. With regard to palpation of the ureters in the knee-and-hand position, he thought that the proportion of cases was small in which it could be of any value. He had never seen the slightest reason to forbid rapid dilatation of the urethra. Median urethrotomy was not unfrequently performed by him for the mere relief of frequency of micturition. In resorting to nephrectomy after nephrotomy, it should be our earnest hope that nephrectomy will not be needed.

Mr. J. STARTIN showed some cases of Lupus treated by caustics.

YORKSHIRE ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.

THE annual meeting of this Association was held at York on the 27th ult., Mr. S. W. North, President, in the chair. After the transaction of routine business,

The PRESIDENT delivered an address, in which he enumerated the advantages caused by the formation of the Society and briefly reviewed the questions of legislation with regard to the sale of milk, over-pressure in education, and legislation affecting the care and treatment of infectious diseases in hospitals.

Dr. HIME (Bradford) read a paper on the Germ Theory of Disease, in which he showed the basis of belief for what is known as the germ theory, traced out the leading events in its history, and showed the position in which it stands at the present time as a scientific theory fully verified by facts. Having alluded to the work done by Robert Boyle, Henle, Pasteur, and Koch, Dr. Hime stated that it was in surgical practice that the truth of the germ theory first bore its fruits, and to England, in the person of Sir Joseph Lister, was due the glory of having established a method of surgical practice which had not only rendered familiar operations free from danger, but had made possible operations which a few years ago it would have been considered criminal to attempt. Dr. Hime said the bearing of that important theory upon public health was of very wide extent. If they really had ascertained the specific cause of consumption, anthrax, pneumonia, diphtheria, typhoid fever, and a number of other of the greatest plagues of humanity, more than the first step had been taken towards successfully combating those diseases. But they could not hope for rapid progress in this country while they were hampered by measures which entirely prevented the possibility of scientific research, and which, while it rendered perfectly legal the killing of rats and other vermin with the wanton intention of merely getting rid of them, rendered it a penal crime to inoculate a rat or a mouse with the object of saving human life.—A discussion followed, in which Drs. Low and Spencer and Mr. North took part, and Dr. Hime briefly replied.

WOLVERHAMPTON DISTRICT MEDICAL SOCIETY.

A MEETING was held in the Bell Medical Library, Wolverhampton, on Feb. 5th, the chair being taken by E. Crockett, Esq.

Dr. S. A. SMITH of Bilston read a paper on Puerperal Fever. After defining his terms, carefully enumerating the causes and graphically describing the varieties, he gave some interesting and instructive details of two local epidemics which occurred in 1873 and 1884. The discussion was maintained by Dr. Lycett, Mr. Crockett, and Mr. Jackson, and adjourned till the next meeting.

Mr. VINCENT JACKSON exhibited a girl who was able to walk six weeks after he had excised her knee; also an ossifying enchrondroma removed from the femur.

Dr. DINGLEY showed two Brains; one with a large hæmorrhage into the pons Varolii, and the other with an abscess in the temporo-sphenoidal lobe and meningitis from otitis in scarlet fever.

Reviews and Notices of Books.

Lectures on the Nervous System. By T. GRAINGER STEWART, M.D., F.R.S.E. Edinburgh: Bell and Bradfute. London: Simpkin, Marshall, and Co. 1884.

DR. GRAINGER STEWART'S lectures on the Nervous System, in their printed form, constitute a series of articles excellent alike in the manner in which they are written and in the matter which they contain. The qualified practitioner will find in them a pleasant means of passing a few hours whilst recalling the main facts in connexion with diseases of the nervous system. To the student not yet initiated into the mysteries of neurology these lectures will act as a faithful guide, whilst to the advanced student they will serve the purpose of helping him to discriminate between the main and subsidiary facts of the diseases of the nervous system. The first three lectures open naturally enough with the medical anatomy of the nervous system; then follow three more lectures dealing with aberrations of the sensory functions; the next two treat of the disorders of motion; the ninth lecture is taken up with the uses of electricity in diagnosis; whilst the tenth is concerned with the disorders of vaso-motor and secretory nerves, together with the examples of trophic disorders usually attributed to disturbances of some parts of the nervous system. The alterations in the cerebral and mental functions form the subject of the twelfth lecture. Language has a lecture to itself, which we have read with the pleasure of revived memories, for Dr. Stewart is an acknowledged master, so far as mastery is possible, of this most difficult subject. The thirteenth lecture seems at first sight not to follow the orderly succession of the previous lectures, but that does not detract from its value; it is a brief chapter on the general pathology of nervous diseases. The general treatment of nervous diseases is dealt with in the concluding chapter. There is no need to review the work at further length; it is a safe guide, and contains nothing which the student will have to unlearn. This notice cannot be concluded without reference to the numerous and most excellent illustrations.

The Public Health Act, 1875. Annotated, with an Appendix, &c., by W. G. LUMLEY, Q.C. Second Edition, edited by W. PATCHETT, Q.C., and ALEXANDER MACMORRAN, M.A. London: Shaw and Sons, Fetter-lane.

THE special feature about the second edition of this work consists in the detailed information given in the notes and annotations which are appended to the majority of the sections. A large number of these notes relate to matters which come more especially within the cognisance of those who act as legal advisers to sanitary authorities; but on looking at those clauses of the Act which relate essentially to work with which the medical officer of health is concerned, it is evident that the explanations given will be very useful to all who have to do with the sanitary administration of the country. The definition of the term "nuisance," as determined in the case of the Malton Urban Sanitary Authority *v.* the Malton Farmers' Manure Company, from which it may be inferred that it is not necessary to prove injury to health when offensiveness to the senses and consequent interference with the enjoyment of life is proved, is entered into, and it is a matter that needs to be more widely understood than it is. Useful explanatory comments follow sections 42 and 44, dealing with the different provisions as to removal of refuse, nuisances from animals, &c., and the reference to the unfortunate decision in the case of Heap *v.* Burnley Sanitary Authority brings the work up to the present date in the matter of distance bye-laws as to piggeries. In connexion with section 124 it is explained that the hospital or place to which patients may be removed compulsorily has been construed to apply to the infirmary or sick wards of a workhouse. Possibly this may be so, but we feel convinced that the intention of the clause was not to allow a person to be made a pauper against his will merely in the interests of communities that had failed to provide themselves with proper means of isolation, and we know of instances in which an attempt to procure removal to workhouses under this section has failed for the reason which we name. A somewhat similar point arises in a note to section 131, relating to hospital provision, where it is explained that the word "inhabitants" does not properly apply to paupers. This we think is an unfortunate comment, for although the guardians of the poor have certain definite responsibilities in regard to paupers whatever the nature of the sickness may be from which they are suffering, yet we know nothing that compels them to isolate the sick in the interests of the public health; and as a matter of fact the number of authorities who receive the inhabitants of their districts into sanitary hospitals quite irrespective of the question of pauperism is largely on the increase. Indeed, as is well explained in another portion of the annotation referred to, special statutory provision has been made for the transfer of hospitals for infectious diseases from the guardians to the sanitary authorities, so that the latter may undertake all the work of isolation. Some of the annotations extend over several pages, and will be found of extreme value both for the explanations they give and for the cases they cite, and on not a few much careful labour has evidently been expended. Following the Public Health Act, 1875, are a large number of other Acts, either in their entirety or in part only, which are referred to in the sections or annotations of the principal Act, and some notes are also appended to these latter. The index also appears to be well compiled. The volume exceeds a thousand pages, and this we suppose is an excuse for the entire absence of all orders issued by the Local Government Board under the Public Health Act. This absence is, however, a very considerable drawback to the work as a volume of reference for officers of health, but it is one that may be remedied in a future edition. Regarded as a whole, the work has exceptional merits; it supplies in one volume the statutes relating to health and local government, it gives explanations and quotes cases on obscure points with an amount of completeness and detail not heretofore attempted, and though it may not in every respect be perfect, it is unquestionably the best work of its sort which has as yet been published.

OUR LIBRARY TABLE.

The Journal of Anatomy and Physiology. Conducted by Professors G. M. HUMPHRY, W. TURNER, and J. MCKENDRICK. Vol. 19, Part 2. January, 1885. London: Macmillan and Co.—This part contains the following articles:—J. Bland Sutton: on Diseases of the Reproductive Organs in Frogs, Birds, and Mammals, with a plate. J. Duncan Matthews:

on the Oviduct in an Adult Male Skate, with a plate. Dr. James Davison: on the Influences of some Conditions on the Metamorphosis of the Blow-fly, chiefly dealing with the effects of different coloured lights and different temperatures. Dr. J. Charles: on the Sources and the Excretion of Carbonic Acid at the Liver. He thinks it proceeds from the decomposition of the proteids. Dr. A. M. Paterson: on a Method of Maceration. By the method described he finds that to make a jaguar's skeleton four months are required, and to make that of a zebra one month. David Hepburn: on Floating Kidney. Thomas Dwight: on the Movements of the Ulna in Rotation of the Forearm—an interesting paper in which the author contests Professor Heiberg's well-known conclusions. Alex. Hill: Dissection of a Double Monster. Professor Turner: on the Relation of the Alveolar Form of Cleft Palate to the Incisor Teeth and the Intermaxillary Bones; also, on the Dumb-bell-shaped Bone in the Palate of Ornithorhynchus compared with the Prenasal of the Pig; also, on the Infraorbital Sulcus; also, an additional note on the Oviducts of the Green Shark. Drs. R. T. Sutherland, R. J. Anderson, and J. C. Russell: Notes on Dissection.

A Statistical Chronology of Plagues and Pestilences, as affecting Human Life, with an Inquiry into their Causes. By CORNELIUS WALFORD. Pp. 151. London: Harrison and Sons. 1884.—This paper was read at the Statistical Society in 1883, but was not published in their journal on account of its length, and being in some other respects not suited for it. The title indeed seems a misnomer, for the paper is rather remarkable for the absence of information in a tabular form, and for the want of that precision of statement which is generally understood to characterise statistical investigations. As an instance of the latter defect, we may quote, from the chronological list of plagues and pestilences given in the Appendix, the notice of the cholera at Gibraltar in 1834: "*Gibraltar.* — Cholera attacked nearly everyone on the Rock," whereas official documents show that in a population of about 20,900 only 1686 cases occurred, with 414 deaths. The book, however, contains much curious and interesting information, especially on "the indirect causes, celestial and terrestrial," of plagues and pestilences, and on "plague prevention and remedies," the latter being divided into saintly and secular. The compilation of the book must have involved a great amount of labour, and it will doubtless prove useful to persons following out inquiries as to the prevalence of various epidemic diseases at different periods. The author informs us that this paper is to be followed by others on the Periodicity of Plague Visitations, the Spontaneous Origin of Disease, and on Pestilential Cyclones.

The Classified Directory to the Metropolitan Charities for 1885. Tenth Annual Edition. By W. F. HOWE. London: Longmans, Green, and Co.—This work contains full information of above 1000 metropolitan charitable institutions, all the religious, medical, educational, reformatory, preventive, relief, and other charities being grouped or classed under their respective headings, together with an appendix containing a list of similar institutions in England and Wales. To those interested in the removal of the troubles of their less fortunate fellow-creatures such a book cannot fail to be useful, for with its assistance the benevolent can with ease select the most suitable institution for their charity, or for any person whom they may wish to benefit, whether the case be blind, deaf, dumb, incurable, sick, aged, an orphan, homeless, &c.

New York Medico-Legal Journal. Pp. 200.—The December number of this periodical fully sustains the reputation obtained by previous issues. Besides an account of a number of miscellaneous subjects of medico-legal interest, we find some valuable contributions by well-known authors, home and foreign. Dr. T. Stevenson of London communicates a paper on Poisoning by Canned Foods, in which he argues that there is not sufficient evidence to show that the toxic symptoms hitherto observed are referable to ingestion of metallic compounds such as of zinc and tin. An exhaustive comment is given by Dr. Clark Bell, the President of the New York Medico-Legal Society, on the Relations of Madness to Crime. The author reviews the English and American Criminal Law on the responsibility of the insane in incisive but judicial terms. Quotations are given from the writings of leading alienists in England, whilst Sir Fitzjames Stephens' exhaustive work on the Criminal Law of England is laid largely under contribution. The cases of Gouldstone and Cole, tried at the Central Criminal Court in this country, are cited in support of the contention that the existing Acts of the Legislature are inconsistent with the present state of medical knowledge. Two cases are recorded where lunatics were brought before the Ecclesiastical Courts in America. In one of them a woman was expelled from church fellowship on account of apparent misconduct, but the verdict was eventually rescinded on the proof of insanity being established. An abridged but trustworthy report is given of the debate in the House of Lords in May, 1884, on Lunacy Reform in Great Britain. We are glad to see in the list of corresponding members the names of many British authorities on forensic medicine and insanity.

The American Journal of the Medical Sciences. Edited by J. MINIS HAYS, M.D. New Series, Vol. 89. Philadelphia: Lea Brothers and Co. 1885.—This bulky volume contains a large amount of information of a very serviceable kind. The original communications are fifteen in number. The section devoted to reviews of books and pamphlets is very lengthy. An admirable quarterly summary of the improvements and discoveries in the medical sciences constitutes the third division of the journal. The work thoroughly deserves support from English practitioners of medicine. Among the original articles we may mention the following:—A Contribution to Jacksonian Epilepsy and the Situation of the Leg Centre, by Wm. Osler, M.D., F.R.C.P.; Poliomyelitis Anterior in Adults, by Gustavus Eliot, M.D.; Psoriasis, Verruca, Epithelioma—a sequence, by J. C. White, M.D.; a case of Unilateral Spasm of the Tongue, by E. C. Wendl, M.D.

Zeitschrift für Biologie. Edited by W. KÜHNE and C. VOIT. Band 20, Heft 4. 1884.—The memoirs contained in this part are, Max Rubner: On the Action of Acetate of Lead on Grape and Milk Sugar. 2. On the Heat becoming Latent on Solution of Urea in Water, by the same author. 3. Professor Axel Jäderholm: Studies on Methæmoglobus. 4. Dr. K. Mays: Histo-physiological Researches on the Distribution of Nerve in Muscle. 5. W. Kühne: Reply to the Remarks of E. Du Bois-Reymond on Multiple Nerve Endings in one Fibre. 6. D. Th. Pfeiffer: On the Quantitative Estimation of Urea by the Litrimetric Method. Dr. W. Cameron: On the Metabolic Processes in Five Children varying in age from five to fifteen years.

Lectures on Nursing. Delivered to the Probationers of the London Hospital Training School for Nurses. By EVA C. E. LÜCKES, Matron to the London Hospital. London: Kegan Paul, Trench, and Co.—We heartily commend these lectures to all who are being trained for nurses. The spirit displayed and commended is of the very best, and the systematic treatment of the chief parts of nursing duty and the description of details are equally good. No part of the book is better than that in which Miss Lückes defines the duty and sphere of the nurse as distinguished from those of the medical man, and in which she warns nurses against all quackery and assumption of medical duties.

VACCINATION GRANTS.—Mr. William Dobson of Leeds (second time), and Mr. O. Lowsley of Reading (sixth time), have received the Government grants for efficient vaccination.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 14, 1885.

THE communication made by Dr. KLEIN at the last meeting of the Royal Society will excite widespread interest, for it contained in substance the results of the inquiry instituted by the Cholera Commission of which he was the leading member, and it came in anticipation of the detailed report. From the preliminary notices that have hitherto been published it can readily be imagined that the chief portion of Dr. KLEIN'S work has been directed to the question of the relation of Dr. KOCH'S now famous "comma bacillus" to cholera. And here at the outset it is well to remember that KOCH himself has expressed the belief that the organism known by that name more strictly belongs to the group of spirilla. Dr. KLEIN sufficiently showed that it is incorrect to speak of it as comma-shaped, for the curved body, forming a segment of a fully formed spirillum, is of uniform diameter throughout. Dr. KLEIN, however, thought it more allied to the vibriones; and here Professor LANKESTER differed from him. Professor LANKESTER advanced the opinion that Dr. KOCH had adhered to the term "bacillus" because in the first instance in Egypt he had discovered in cholera cases a bacillus like that of glanders—a straight, rod-shaped organism, and wholly different from the organism which he subsequently declared to be specific to cholera. Although, no doubt, it is desirable that nomenclature should be accurate, and that it should be based strictly upon morphological characters, it is perhaps the least important part of the whole subject. As to the constancy of these micro-organisms in the choleraic evacuations, Dr. KLEIN was in perfect agreement with Dr. KOCH, and he noted the great variations they exhibit in form and size, as well as in number, in different cases. An important and almost crucial divergence occurs between the statements of the German and English Commissioners as to the abundance of the bacilli in the intestinal contents and intestinal wall in cases observed very early after death. Dr. KOCH, it will be remembered, declares that the earlier the examination the more likely are these bacilli to be found in a state of purity in the rice-water fluid and in the tissue of the mucous membrane, where he figures them as penetrating within and around the tubular glands. In acute cases this freedom from admixture with other forms of bacterial life led him to aver that in such circumstances the lower part of the ileum contained almost a pure cultivation of comma bacilli. Dr KLEIN and his colleagues cannot confirm this statement, and have never observed any bacteria whatever in the mucous membrane and epithelium in cases examined a very short time after death. They contend, therefore, that the multiplication of the comma bacilli with their penetration into the mucosa is a post-mortem circumstance, and that in this respect no difference is to be noted between these organisms and other putrefactive bacteria; and they account for the difference in result of the two observations by the simple fact that Dr. KOCH'S examinations were made at a much longer interval after death than were theirs.

The absence of micro-organisms in the blood and tissues of the choleraic subject was noted by Dr. KOCH, and has been confirmed by the English Commission, so that both differ from the statement on this point made by the French Commission. This negative fact has been held as opposed to Dr. KOCH'S doctrine that cholera depends upon a specific organism; but his view that the action of the bacilli is limited to their production of a poisonous substance rapidly absorbed from the intestines into the blood is adequate to explain the fact. Of course, Dr. KLEIN does not admit this explanation, upon the ground that the comma bacilli are so very sparse in the early observed post-mortem examinations. Another and equally important difference upon a point of observation is as to the behaviour of the micro-organisms under cultivation. At a recent meeting of the Medical Society Dr. HERON exhibited cultures of the comma bacillus in gelatine, and pointed out how strikingly these differ from the cultures of the morphologically similar organisms discovered by FINKLER and PRIOR in the evacuations of cases of cholera nostras. Last summer Dr. LEWIS drew attention to the presence of similarly formed organisms in the buccal secretions, and more recently Dr. DENEKE has met with them in cheese. Dr. KLEIN has also found them in diarrhœa, and Dr. GIBBES is said to have found them "in astonishing numbers" in the intestines of cases of dysentery and phthisis; whereas Dr. KOCH said that although he had sought for them in such and other diseases he had never detected them except in cholera. There can be little doubt then that numerous micro-organisms exist having the same (or almost the same) morphological characters—spirillar rather than bacillary in type; and unless any more distinctive characters than those obtained by microscopical examination were established, the whole utility of the detection of their presence in choleraic stools, to say nothing of the alleged specificity of the comma bacillus of cholera, would fall to the ground. Dr. KLEIN has made cultivations of the comma bacilli from the mouth, and he exhibited them side by side with cultivations of the cholera bacillus, to show that the most critical inspection would fail to discriminate between them. In each case the funnel-shaped depression at the point of inoculation and the resulting limited liquefaction of the gelatine were reproduced with equal fidelity. Moreover, under altered conditions the cholera bacillus can show great variations in its mode of growth; and altogether the "culture test" has failed in the hands of Dr. KLEIN to establish any specific quality of the bacillus. Since returning to London, Dr. KLEIN has made further observations on this point, and has shown that when cultivated in agar-agar jelly the comma bacilli undergo a kind of longitudinal fission, so as to be converted into circular organisms, which eventually divide into two semicircular comma bacilli. Dr. DENEKE found in the cheese spirillum certain variations in the mode of development as compared with that of the cholera bacillus; but, in the face of these observations of Dr. KLEIN, it may be asserted that such variations are not greater than are to be observed with the cholera bacillus alone. So much stress has been laid upon this "culture test" that it is evident the subject will have to be again most thoroughly investigated. There is another point in

connexion with the growth of the comma bacillus in which these authorities are opposed, and, as upon this Dr. KOCH has based an explanation of the immunity of healthy individuals, it may be referred to. It is well known that some bacteria thrive best in alkaline or neutral media, others in acid. The comma bacillus requires the former, and does not grow at all in the presence of acid. But, as Dr. KLEIN pointed out, an inability to grow in a given medium is not the same thing as destruction by it, and he quoted experiments to the effect that after subjection to the action of acids the bacillus retained its power of growth when transplanted to appropriate soil. Again, in opposition to Dr. KOCH, Dr. KLEIN has proved that drinking-water contaminated with the presence of these bacilli does not cause cholera, as shown by his observation of the tanks of Calcutta recently published (*vide* THE LANCET, Jan. 31st, p. 221). The last point of difference lies in the results of inoculation experiments. It is well known that Dr. KOCH declared he was unable to communicate the disease to the lower animals either by feeding or inoculation; but since the success attending the experiments of NICATI and RIETSCH—viz., of intra-duodenal injection of the culture products,—the communicability has been alleged to be possible; and Dr. KOCH himself has repeated such experiments satisfactorily. Dr. KLEIN and his colleagues made many such injections in animals with nothing but negative results; and he explained that the only way he could account for this difference was that the climate favoured recovery from the injury done to the animal by the operation, an injury to which he attributes all the symptoms alleged to be choleraic and due to the introduction of the bacilli into the intestine.

Such, then, being the conclusions which the English Commissioners have brought us, it may be asked whether they have been content with the iconoclastic labour of dispelling the comma-bacillus myth? Have they anything to replace it—any addition to our knowledge? Well, it appears that they, too, have discovered a bacillus—straight and much smaller than the comma-shaped organism—in the mucous corpuscles found in the intestinal contents of a rapidly fatal case; but they failed to detect any specific characters in its cultures, or to find it in the blood, or to produce any effect by inoculation of animals with it. At the same time, Dr. KLEIN thinks that there is just as much reason for regarding this bacillus as the true cholera organism as there is in favour of the comma bacillus. He repudiates the notion that it should be so considered; for in the one case, as in the other, no characters are exhibited different from those presented by ordinary putrefactive bacteria. He incidentally mentioned that Dr. KOCH was about to proceed again to India to continue his researches; and we cannot help thinking it would be desirable that, instead of independent commissions from every country, there should now be formed an International Scientific Commission to investigate the subject anew. As the question now stands, there are in dispute not merely matters of inference, but essential matters of fact and observation; and so great are the interests at stake, and so important is it to arrive at the truth of the relation between Asiatic cholera and these bacterial organisms, that we trust a means will be provided for such further impartial and exhaustive inquiry. A distinguished Fellow, whose experience of disease in India is very large, expressed the opinion that the promulgation of Dr. KOCH'S doctrine had been most disastrous, and that it was responsible for the panic that attended the appearance of the disease in Europe last summer. We do not concur in this view; for if Dr. KOCH'S discovery had been substantiated, instead of creating panic it should have tended to allay it, for, as he has pointed out, it would strengthen the hands of those who know that in the early adoption of sanitary measures lies the greatest safety; and a sense of security would be felt if the actual cause of the disease could be known and combated. So many of the known facts concerning cholera harmonise with the germ doctrine that, in spite of the check administered to Dr. KOCH'S position by Dr. KLEIN, it would not be surprising if research eventually prove the views of the former to be very near the truth. The value of the work of the English Commission may then appear to lie in its having done much to clear the way for further research which it would be worse than folly now to neglect. Some talk and write as if the discordant results arrived at prove that it is vain to pursue the subject further; and others regard the results of the English Commission as having dealt a *coup de grâce* to a too hastily framed conclusion; but this is not the spirit in which the subject should be approached, and Dr. KOCH is no more likely to abandon his position at present than he was to submit to Dr. SPINA'S onslaught upon the value of the discovery of the bacillus tuberculosis. It is as ungenerous as it is unscientific to refuse to hear him, or to hastily declare that there is no room for further investigation of the matter.

FEW facts in reference to the sick and their welfare are more noticeable than the development of the art of nursing in recent years. Twenty years ago nursing was a luxury very much monopolised by hospital patients, and even in their case the luxury was somewhat of a coarse character. There were, of course, good, kind, and wise women in those days who had quick sympathies with the sick, and whose presence and ministrations in wards were like those of a mother or a good angel, but they were not plentiful, and the work done was often performed unskilfully and untenderly. It is not pleasant to recall what must have been the sufferings of the sick in earlier days in poorer hospitals, especially in Poor-law hospitals, when given over for the night to the care of a nurse not considered good enough for day duty, and who prepared herself for her nocturnal work by copious potations of beer. The cry for a cup of water or for a change of posture by a thirsty or restless patient was often unheeded, or only heeded to be rebuked. When kindness was not at fault, intelligence was often wanting, and superstition and ignorance had it all their own way. The best proof that this is not an exaggeration is to be found in the prejudice which still survives against professional nurses. There are large numbers of educated people who would not consent on any terms to have a "hospital" nurse. It can scarcely be imagined that their objection is to the training received in hospitals. It must be traceable to experience of the old order of nursing, or to the survival of some of its bad traditions. The old order of nursing is not quite extinct. Practitioners of any standing could still give instances of nurses whose coarse ignorance and unkindness brought discredit on the order who put the wrong end

of the clinical thermometer into the mouth, who seemed to think less of the patient than of themselves, who conceived of nursing as a calling requiring a large amount of stimulant, and who disgusted all the other members and servants of a household by the assumption of airs of superiority which neither their nursing powers nor their general intelligence justified.

It is well worth the attention of all persons interested in nursing as a calling and in the welfare of the sick to consider the reasons for the existence of a still great amount of prejudice against trained nurses. Some of it is to be explained by too hard a view of their function in coming into a house, and by the absence of sympathy, sometimes sympathy even with the patient, who is treated too mechanically, as a mere model requiring dressing or bandaging. But a more common fault is the want of sympathy with friends, and the exaction of too much service from servants who are probably already overtaxed. It would be unreasonable to expect perfection in nurses. The very training they are subjected to gives them that little knowledge and that familiarity with big words which are apt to spoil simplicity and to produce conceit. But after all this criticism—and it is neither ill-natured nor unjust—truth compels us to say that medical men owe very much of their greater success in treatment to the greater efficiency of nursing, and that that patient who with an acute or prolonged disease refuses the help of a good nurse, not only does an injustice to the members of his household, but sensibly diminishes the chances and the rate of his recovery; and that for one nurse who is selfish or inconsiderate or incompetent there are ten who are serviceable and sympathetic, and who add infinitely to the comfort of a sick-room and to the good chances of a patient. Every now and again one meets with a nurse whose art is in every sense a fine art, and in whose way of making the bed of a patient, preparing his food, or dressing his wounds, there is an element of genius that is missing in all the boasted art of men. That this is likely to be a more and more common experience it is quite reasonable to hope, seeing the number of capable and refined women who give themselves to this work and to the training of others for it; and to the help which earnest and distinguished members of our own profession afford in the education of nurses. Nursing must, in truth, be a fine art, or it is nothing. It is a calling in which coarseness is almost a crime and in which every duty should be done delicately and lovingly. The presence of heavy-headed and heavy-footed people with hard hands and harsh voices in a sick-room is the best illustration possible of an *error loci*.

THE official report[1] which has been prepared for the Local Government Board by Dr. PARSONS, on the extensive epidemic of enteric fever which took place last autumn at Kidderminster, has been laid before the Corporation. The epidemic is probably the most severe which has been met with in this country within recent years; indeed, from the 15th of August to November 14th, the period to which the report relates, the number of attacks is estimated as having been 1200, and the deaths, which were not specially numerous, amounted to 89. The report is one of very considerable length; it deals somewhat exhaustively with statistics and with the conditions in the town which might give rise to such an epidemic, and it specially points out the circumstances which came under suspicion in so far as the causation of the disease is concerned. During the thirteen years previous to 1884 the average annual "fever" death-rate for Kidderminster was somewhat under that for England and Wales as a whole. Up to August last only seven "fever" deaths were registered during 1884. In the first fortnight of that month twenty cases occurred in seventeen households, and then followed the outburst of disease, for in the ensuing fortnight 110 fresh households were attacked, the new cases being 141 in number. From that date the disease continued with striking force until the result we have already recorded had been brought about. Originally the outbreak had been attributed by the borough engineer to the nuisances in connexion with midden privies, and no words are too strong in which to condemn the filthy arrangements which have prevailed in Kidderminster in this matter, but they did not afford an explanation of the outbreak. The milk-supply as a vehicle of infection could also be set aside. Sewers and drains have largely come under suspicion, and grave defects attach to both. As regards the sewers, catchpits holding putrefying filth are, for some unaccountable reason, constructed in connexion with the manholes; heated liquids from factories may have afforded a state of sewer temperature specially favourable to the propagation of enteric fever contagium; no provision has been made to prevent the forcible ascent of air from the main sewer into the branches in the higher levels; the flushing arrangements have been defective; and having regard to the absence of arrangements for the relief of foul air on the entrance of volumes of liquid, the sewers must be regarded as of small capacity. The house drains are also defective, disconnexion and through-ventilation—the only safeguards against sewer poisoning—being but rarely carried out. Again, the question of water-supply as a cause of the epidemic came under consideration. The possibilities of a general contamination of the town water at the source, and also of local contaminations through reflux of foul matters into the terminal branches, are discussed at considerable length, and some lithographic plates are added, with a view of explaining some of the conditions which are considered. The sudden and severe character of the outbreak, the universal distribution of the fever over the area supplied by the ramification of the Kidderminster mains, and a dangerous proximity of one of the wells to sewage works receiving sewage which contained the excretions of cases of enteric fever in August last, go strongly to point to water pollution. There was also a large incidence of fever upon water drinkers, and indications of impurity in the supply were noticed at intervals. Chemical evidence was indeed arrayed against these points, and was adduced in support of the wholesomeness of the supply, but since the chemist has failed to detect both cholera and enteric fever stools when deliberately added to water, such evidence has little weight. But even on this point Dr. DUPRÉ, using a new test, showed that though the suspected water when judged by the ordinary tests was very good, yet the loss of free oxygen from the fully aerated water on standing twelve

[1] Sold by Knight and Co., Fleet-street, E.C.; Shaw and Sons, Fetter-lane, E.C.; Hadden, Best, and Co., West Harding-street, E.C.; and P. S. King and Son, King-street, S.W.

days in a closed bottle was very great, a result "strongly pointing to sewage contamination." And when measures had been taken to prevent the recurrence of any possible soakage of sewage into the well, a fresh sample exhibited "a very decided improvement" in this respect. The case was, however, not one in which the precise means of pollution could easily be detected and pointed out. Difficulties arose at several stages of the inquiry, and the defective conditions of sewerage and excrement disposal formed additional complications in so far as they tended to facilitate a diffusion of the infection. Dr. PARSONS, indeed, says "the cause of the outbreak cannot therefore be with certainty assigned; possibly it has not been one and the same in all cases." The conclusion is perhaps safe from a strictly scientific point of view, but it is the reverse of a bold one; and, judging from the report itself, we should have been inclined to conclude that contamination of the water-supply was the cause of the outbreak, and that the spread of the disease was materially facilitated, indeed ensured, by the sewers, drains, and privies. In so far as there are difficulties in adopting this view, we think those difficulties relate to points of minor importance. Had it been possible to clear them up the result would have been more satisfactory, but the fact that some points remain unexplained hardly suffices to throw material doubt on the pollution of the water-supply as the prime cause of the epidemic. The report is worth careful study and perusal, both from this and other points of view.

DURING the past ten days the movement for a Teaching University in London has made considerable progress. The proposals which were put forward at the first meeting by the provisional committee were withdrawn at the meeting on the 3rd inst., and the following objects of the Association were passed without a dissentient:—

"(1) The organisation of university teaching in and for London, in the form of a Teaching University, with faculties of Arts, Science, Medicine, and Laws. (2) The association of university examination with university teaching, and direction of both by the same authorities. (3) The conferring of a substantive voice in the government of the university upon those engaged in the work of university teaching and examination. (4) Existing institutions in London, of university rank, not to be abolished or ignored, but to be taken as the bases or component parts of the university, and either partially or completely incorporated, with the minimum of internal change. (5) An alliance to be established between the university and the professional corporations, the Council of Legal Education as representing the Inns of Court, and the Royal Colleges of Physicians and of Surgeons of London."

An executive subcommittee was formed, with full powers to draw up a scheme for the consideration of the members at a subsequent meeting. With the first, second, and third objects all will agree, and they will present no difficulty; but the negotiations which will be necessary to carry out the last two objects must obviously be very delicate, and we doubt very much if they will be successful. On the 8th inst. the special committee of forty members appointed by the Convocation of the University of London to consider the proposals published by the Association for promoting the establishment of a Teaching University for London met at Burlington-gardens, and on the motion of Lord Justice FRY, seconded by Sir JOSEPH LISTER, unanimously resolved—

"That in the opinion of this committee the objects of the Association for promoting a Teaching University for London would, if carried into effect by this university, add to its usefulness and importance."

A special meeting of Convocation will be called at the earliest opportunity, and the committee will ask for full powers to take action in the matter, either side by side with the Senate as the executive authority, or without its assistance, as that body may determine. This action of the committee almost necessarily compels the Senate to take some part in the movement, and we fear that this will be the "rock ahead." So far as the faculties of Arts and Science are concerned, it may be possible to give degrees in the same institution to candidates with special certificates of attendance on lectures and to those who have had no collegiate training, and to have different examiners for the two classes of students—viz., their own teachers in the one case, and external professors in the others; but the expedient seems to us most clumsy and unnecessary. The real difficulty is with the degrees in Law and Medicine. No action which the Senate of the University of London can take will satisfy the legitimate wants of the London teachers and students without seriously lowering the value of the present degree; and it is because we recognise this that we would urge the authorities of the University to go on with its own great work as at present, and leave the promoters of a Teaching University for London to establish a new institution. The demands which the University of London will be asked to meet may be seen by the following extract from a report which has been adopted by the Council of the Metropolitan Counties Branch of the British Medical Association.

"That, in the first place, the University of London be requested—(*a*) To modify its regulations and procedure, so as to adapt them to the requirements of the medical profession in England; (*b*) to reconsider and modify the two preliminary examinations; and (*c*) to admit upon the Senate, as members of the Senate, a certain proportion of representatives of the metropolitan medical schools."

It is difficult to suppose that the University of London will be inclined to grant such a request; and if the Teaching University movement be not kept apart from the existing University and be allowed to make its own conditions, it will be of no use to the medical profession.

THE Surgery of the Kidney formed the subject of a discussion at the Medical Society on Monday last, opened by an able paper by Mr. HENRY MORRIS. As far as possible he avoided the ground which has been recently traversed at the Medical and Chirurgical Society, and without discussing the relative merits of the lumbar and the abdominal incision for nephrectomy, he limited himself chiefly to a consideration of the surgical aspects of renal calculus. The first part of his paper was devoted to a discussion of the diagnosis of this affection, or rather to insisting upon the difficulties this problem may present. The results of exploration of the kidney for stone have brought this fact into strong relief, for Mr. MORRIS was able to refer to a long list of cases in which surgeons have cut down upon a kidney expecting to find a stone, and yet have found none.

No doubt in some of these the exploration has been imperfect, and a stone has been overlooked; and in view of the possibility of this occurrence, it is now recommended that the exploration be not regarded as satisfactory until the surgeon has made an incision into the kidney, and through this has thoroughly explored the pelvis and calyces of the kidney with his finger. The simple incision down to the kidney is an operation of no difficulty, and of little danger; the incision into the kidney substance adds somewhat to the difficulty and risk, but is chiefly of importance in that it prolongs the convalescence, and exposes the patient to the annoyance of urinary fistula. The condition which is most likely to be mistaken for renal calculus is early scrofulous disease of the kidney, and it is probable that an incision into the organ under this condition is of advantage, as it affords exit to pus and caseous débris. Unfortunately Mr. MORRIS was unable to give any new and certain guides in the diagnosis of these affections, or of the other conditions likely to be mistaken for renal calculus, and had to content himself with indicating the difficulties, and urging care and deliberation before deciding upon operative procedures. Mr. MORRIS pointed out the importance of searching for calculi impacted in the ureter. He has himself removed from the lower end of this tube a stone which was impacted just at its orifice in the bladder and to this operation he gives the name of vesico-ureterotomy—a name which forcibly reminds us that, however excellent modern surgical advances may have been, they have given birth to many ugly names. Reference was also made to a case, at present unpublished, in which a stone was removed from the upper end of the ureter through an abdominal incision; the patient unfortunately died from advanced disease in the opposite kidney. This brings us to a third point in Mr. MORRIS'S paper, upon which stress was again rightly laid—viz., the difficulty of determining the condition of the opposite kidney where an operation is required for the diseased organ. Dr. TUSCHMANN subsequently referred to an instrument he has used in very many cases for compressing the vesical orifice of one ureter and so allowing of the collection of the excretion from the opposite organ only. At present more experience of the value of this instrument is needed before full confidence can be placed in it, and we understood from Mr. MORRIS that he was not at present able to speak of it with confidence. Probably we shall receive more efficient help from chemistry, and shall be able to estimate from an analysis of the urine how far the existing kidney tissue is efficient for the purposes of excretion.

In regard to nephrectomy, Mr. MORRIS urged that this operation should only be undertaken when the failure of other measures to relieve has shown it to be the only means of curing the patient. In this we are confident he will have the support of every thoughtful surgeon. The removal of a kidney can never be anything but a very grave operation, and certainly for such a condition as floating kidney should never be undertaken until all means by which the organ can be preserved to the patient have been tried and found to fail. Similarly, hydronephrosis often admits of successful treatment by simple puncture of the tumour, and by drainage, either of which is greatly preferable to nephrectomy. In advanced strumous disease of the kidney the conditions upon which an opinion is to be formed are not so simple. The removal of the organ may be of value, both directly and indirectly, by relieving the patient from a source of general infection. But, on the other hand, this grave procedure can never be very successful in cases of advanced disease, where the morbid change is rarely, if ever, limited to one kidney. The success which has attended the simpler and less dangerous operation of nephrotomy seems to turn the scale decidedly in its favour, at any rate as a primary operation, nephrectomy being reserved for the cases in which it fails. The discussion which followed Mr. MORRIS'S paper, although interesting, added in no way to our previous knowledge of the subject. And, indeed, we appear to have reached a stage in this department of surgical practice at which discussion has done all it can, time for the acquisition of enlarged experience being required before we can mark further progress.

Annotations.

"Ne quid nimis."

MEDICAL INSPECTORS OF THE LOCAL GOVERNMENT BOARD.

IT is announced that, at the urgent solicitation of the Local Government Board, and mainly in view of the possibility of an extension of cholera to this country during the coming summer and autumn, the Treasury have sanctioned the appointment of six temporary inspectors to the Medical Department of the Board. We have already recorded that Dr. de Chaumont and Dr. Davies are engaged in port inspection; and we find that Dr. Arnold Royle, C.B., has made some inquiry into a prevalence of fever at Market Weighton, in Yorkshire. The majority of the appointments, if not all, are already filled up. The general survey of the sanitary conditions which prevail in different parts of the country, and which, if left undealt with, may add greatly to the risk of a spread of cholera in our midst, will be of great value from a preventive point of view, and we trust that sanitary authorities will profit by the advice which they may receive as the result.

ARMY MEDICAL SCHOOL.

IT is with feelings of regret that we record the retirement from the chair of Military Medicine in the Army Medical School at Netley of Professor W. C. Maclean, C.B., who has held the appointment there and at Fort Pitt for twenty-four years. Dr. Maclean was educated in Edinburgh, where he took his degree in 1833. He subsequently obtained an appointment in the Indian Medical Service, being posted to the Madras Presidency, in which he served twenty-three years. He was employed on active service in the China War of 1840-42, and was present at the capture of Chusan and of Ningpo. He was subsequently appointed superintendent of the Hyderabad School of Medicine, the first vernacular school of medicine established in India; an appointment which he held for ten years. On the establishment of the Army Medical School at Chatham he was selected by Lord Herbert to fill the chair of Military Medicine, to which he was gazetted in 1861, with the rank of Deputy Inspector-General, when he was placed on the retired list of the Indian Medical Service. In 1871 he was made a Companion of the Bath, and in 1873 was raised to the local rank of Inspector-General of Hospitals. During the long period of twenty-four years in which he has been connected

with the Army Medical School he has been distinguished for the ability, zeal, and regularity with which he has discharged the important duties entrusted to him, the warm interest he has ever taken in the candidates and junior officers, and the happy method he had of imparting knowledge and of stimulating the energies of his pupils. He now retires from his post, under, we presume, the age regulations introduced into the service. He has been a most popular teacher, and will live long in the memories of the numerous officers who have passed through his hands for his high qualities as a professor, a gentleman, and a kind personal friend. He is to be succeeded in his chair by an officer of the Indian Service, Dr. David Boyes Smith, who held the appointment of Principal and Professor of Medicine in the Calcutta Medical College for six years, and is highly spoken of as well qualified for the appointment. He has a difficult task before him to fill the place vacated by such a man as Professor Maclean; and we cannot wish anything better for him and for the school than that he may discharge the duties of the appointment as efficiently as his predecessor.

THE DWELLINGS OF THE PEOPLE.

WE have received the first Annual Report of the Mansion House Council on the Dwellings of the People. The work of the past year has consisted in a general investigation of the sanitary state of the poorer metropolitan districts, the formation of voluntary local committees for this purpose, the study of the action of various remedial measures now in use, and the correction of abuses in 2600 cases. As was to be expected, the members of committees have found much that is defective in the hygiene of the inspected areas. The ancient evils of broken or leaking drains, of intermittent water-supply, overcrowding, dilapidations unrepaired, neglected accumulation of filth, jerry building, and the like, occupy a prominent place in the report. Some difficulty has been experienced in collecting evidence from the occupants of unhealthy houses from their fear of resentment of defaulting landlords, a consequence which is not uncommon, and against which the committees have as a rule been careful to guard their informants. The sluggish action of many vestries in taking up complaints of existing nuisances is much regretted, while the prompt assistance rendered comparatively by a few is as freely acknowledged. In a former notice of the work and aims of the Council we referred to certain amendments of the Sanitary Acts suggested by them. These are set forth in connexion with the above details, and include provisions for the more efficient inspection of districts, for the correction of self-interested conduct on the part of vestrymen, for registration, for the treatment of disease, and for assuring a constant and sufficient supply of pure water to each tenement. With regard to inspection, there is ample evidence to show that the number both of sanitary inspectors and of medical officers of health should be considerably increased, in order that their administration may be an effective reality and not a mere idea. Not the least interesting part of the report is that which deals with various plans for the better construction of the dwellings of artisans. The best of these appear to be that designed by Mr. Booth for the Manchester and Salford Workmen's Dwellings Company, and that by Mr. Hoole for a similar association in Lambeth-road. Both have been tried by the test of experience and found to answer their purpose well. Ventilation, warming, light, and cleanliness are provided for. A point of some consequence is that the system of separate water-closets has been adopted on a cheap and sanitary principle. Among other plans that of "converted courts," and the scheme of Mr. Wynter Blyth, which aims at the institution of a healthy type of one-roomed accommodation, are noteworthy as affording to many of the now overcrowded poor a fairly wholesome halfway house to more convenient living. We have said enough to show that there is need of such work as is done by the Council, and that much good has been accomplished by that body. At the same time much of it is work which requires great tact as well as knowledge for its right performance, such as we think cannot in fairness be at all times expected from a voluntary agency. We would therefore urge the importance, under any new system of municipal government, of giving to sanitary work in its numerous ramifications a far more liberal official care than it now receives.

PROPOSED AMALGAMATION OF SOME OF THE DUBLIN HOSPITALS.

ON Tuesday last a deputation representing those hospitals in Dublin which participate in the Government grants waited on the Lord-Lieutenant with reference to the conditions under which grants are at present given to a considerable number of institutions in that city. His Excellency said that the grants were made with the special object of assisting the sick poor of Dublin, and also for the maintenance of important medical and surgical schools in that city. The governors of the House of Industry Hospitals had applied to the Government for grants to alter the buildings and improve their character, it having been proved that the sanitary condition of these hospitals was unsatisfactory. He had consulted, he said, some eminent gentlemen in Dublin, and there seemed to be but one opinion—viz., that if they could capitalise the principal sums now given by Parliament, they might induce some of the more important institutions receiving these grants to consolidate both their buildings and their management, and by that means not only get rid of the difficulty that now exists as to the House of Industry Hospitals, but do much towards improving the medical instruction which was considered so important when the grants were first made. Some members of the deputation having spoken in favour of the proposal and others against it, his Excellency said he did not expect that the subject could be settled without much consideration; there seemed to be a very considerable difference of opinion, but the Government would not let the matter drop, and perhaps he might shortly be able to make some other proposal to them.

THE BACILLUS LEPRÆ.

THE occurrence of a case of leprosy in the Elizabeth Hospital has afforded Dr. P. Guttmann the opportunity of studying the characters and distribution of the bacilli in the diseased tissue, and he recently gave a demonstration on the subject at the Berlin Medical Society (*Berlin. Klin. Wochenschrift*, No. 6, 1885). Portions of leprous nodules excised from the skin and transferred to alcohol were examined. He says that the detection of the bacilli is very easy, even in unstained fresh preparations; for they are endowed with a characteristic motility, at once apparent when the leprous tissue is teased out in a drop of distilled water and examined with an oil-immersion lens (650 diam.) and Abbe's condenser. Hansen originally observed these movements even within the cells, but of course it is essential that the preparation should be a moist one. These living bacilli are thicker than those which have been submitted to shrinking in the alcohol and stained preparations; in length they vary from a quarter to half or even three-quarters of the diameter of a red corpuscle. They mostly contain spores, which may be placed at the extremities of the bacillus or irregularly disposed in its substance. Koch discovered that the leprosy bacillus has the same colour reaction as the bacillus tuberculosis—i.e., it has a great affinity for methyl-blue in slightly alkaline and alcoholic solution, retaining this stain after the

object has been impregnated with other colouring agents—e.g., vesuvin. Dr. Guttmann confirms the statement of Baumgarten that the bacillus lepræ takes up the colouring matter more rapidly than the tubercle bacillus; but the resemblance between the two is very close. It is thought that the constancy with which the former are found lying transversely in the leprous cells, even in the teased-out preparations, may aid in distinguishing them; but in tubercle the bacilli are also to be found within cells, especially the giant cells. In the leprous nodule the cells are often thickly crowded with bacilli, and after double staining of the sections with fuchsin and methyl-blue the bacillary cells appear red, those free from bacilli being blue. The bacillary invasion commences in the upper layers of the corium, and but rarely attacks the Malpighian layer of the epidermis or the cells of the cutaneous glands. The organism has been found in the leprous tissue, in the mucous membranes of the mouth and larynx, in lymphatic glands, in the liver, spleen, testicle, and in the cornea and nerves. It has also been found in the blood, but it is probable that this observation, unconfirmed by many, is to be explained by the bacilli being pressed out of lymphatics into the puncture made for the purpose of obtaining the drop of blood for examination. There can be no doubt, adds Dr. Guttmann, that these bacilli are the cause of leprosy, although confirmatory evidence has not yet been obtained of the transmission of the disease by the inoculation of animals. Leprosy, however, has never yet been observed in animals.

POISONING BY COKE FUMES.

A CASE, which will probably become historical, has recently been investigated before the district coroner at Pendleton. It is one which introduces many points of interest both to the public and the medical jurist. On January 15th, James Malone, aged sixty-one, his wife, Catherine, aged fifty-one, and their married daughter, Honora Hill, aged thirty-three, retired to rest at 9.30 P.M. According to the evidence given by Hill, she awoke at about half-past four o'clock on the morning of the 16th and found the body of her dead father stretched partly over her. With difficulty she attracted the attention of her mother, who, when told of her husband's death, replied, "I know it; I am dying too; I am suffocated," and she shortly afterwards expired. Hill stated that she tried to obtain relief, but that for many hours was unable to extricate herself from beneath her father's legs, and in vain called and knocked for assistance. Between 4 P.M. and 5 P.M. she managed to leave the house, and, going to a chandler's shop, remarked that her father and mother were dead. From the first she asserted that the room was full of smoke. Dr. J. S. Bury, who made the post-mortem examinations, found some rather severe bruises on different parts of the body of James Malone; but the only one having any important bearing on the case was situated on the chest, and beneath this bruise the ninth, tenth, and eleventh ribs were fractured. Dr. Bury was of opinion that, from the supposed absence of repair of the broken bones, the injury had been inflicted quite recently, not more than two days. Struck with the freedom of the lungs from congestion, and with the absence of other usual signs of asphyxial death, he could come to no definite conclusion as to how the deceased persons lost their lives. Dr. Bury was undoubtedly actuated by a desire to serve inflexibly the ends of justice. At the same time, it is equally clear that he inclined to the belief that there might have been foul play, for we find him saying *à propos* of a suggestion of death from asphyxia, "I should like to know why the man vomited." The positive evidence of injury was present in his mind, and although he freely allowed that such injury was in itself inadequate to cause death, it may still have seemed an indication of the probability of other modes of violence having been resorted to. It was a pity that he was not called after the witness Hill, for then he would have had, to say the least, a very strong suggestion as to what had really happened. The woman's account of what transpired, and her description of her own sensations, form a striking picture of a comparatively rare but deadly form of poisoning. Up to the time of adjournment the theory of poisoning by charcoal fumes received little credit, unsupported as it was by scientific testimony. Before the court reassembled, Dr. Cullingworth was commissioned to conduct a further inquiry; and now a flood of light was let in upon the darkness and confusion. The ribs were shown to have been fractured at least a fortnight, as, although not united, they bore manifest signs of repair. Then came the analysis of the blood of the deceased, with its revelation that carbonic oxide gas had been absorbed in considerable quantity; and, lastly, the stomach presented no trace of liquid or solid narcotic poison. By this time no fact remained which was inconsistent with the theory of death by misadventure. It was proved that the refuse of coke had recently been burned in the grate, and that the chimney was blocked with pieces of wood fixed there by previous residents in the house. So far from vomiting being a rare symptom, it is asserted by Taylor and Stevenson to be of usual occurrence after inhalation of carbonic oxide. Then, *refuse coke* contains sulphur and unstable products of incomplete combustion, and it gives off sulphurous acid, sulphuretted hydrogen, and light and heavy carburetted hydrogen gases in quantity when burned in a close room. The combined action of these gases would explain why, although carbonic oxide was discovered in the blood, the skin and organs did not present the vermilion-red colour ordinarily found after poisoning by *charcoal* fumes. Air mixed with from 5 to 6 per cent. of carbonic oxide gas quickly destroys life, and it is more than likely that before the Malones expired this proportion was approximated. The predominant symptoms are "headache, pulsation in the temples, nausea, *vomiting*, prostration, insensibility and coma." It is a case of pure narcotic poisoning. The oxide is believed to act by preventing the arterial blood becoming venous, just the reverse of carbonic acid. The advanced age of the deceased, their bronchial affections and other infirmities, are amply sufficient to explain why they succumbed whilst their daughter recovered. Some years ago four seamen were taken in a state of stupor to Guy's Hospital. They had been shut up on board ship in a confined place heated with coke, and the chimney had been closed; circumstances exactly parallel to those observed in the "Pendleton mystery" now under discussion. Of these four, two died, aged respectively fifteen and forty; the other two, aged seventeen and twenty-one, recovered. In one of the fatal cases the lungs were congested, in the other not.

THE MEDICAL STAFF OF THE GOVERNOR-GENERAL OF INDIA.

SURGEON A. W. D. LEAHY, I.M.S., has been appointed by Lord Dufferin to be surgeon to his Excellency, as a temporary measure. The permanent incumbent is to be Surgeon Finlay, at present on the staff of the Governor of Bombay. The following officers have been appointed honorary surgeons to the Governor-General:—Surgeon-General W. R. Cornish, C.I.E., Madras Establishment; Deputy Surgeon-General A. J. Payne, M.D., Bengal Establishment; Deputy Surgeon-General W. J. Moore, C.I.E., Bombay Establishment; Brigade Surgeon G. Farrell, Bengal Establishment; Surgeon-Major G. C. Chesnaye, Bengal Establishment; Brigade Surgeon E. H. Roberts, A.M.D.; Surgeon-Major R. Harvey, M.D., Bengal Establishment; Surgeon-Major J. Hector, M.B., A.M.D.; Surgeon-Major S. E. Maunsell, A.M.D.

THE GRADUAL DECREASE OF THE POPULATION-RATE OF FRANCE.

THIS subject, on which we commented last week, continues to occupy the attention of the Académie de Médecine. M. Rochard stated that, if the rate of increase of the population of France continued to diminish in the same proportion as it had done during the present century, there would be no increase at all at the beginning of the twentieth century. France does not compare favourably with other nations in respect of the rate of augmentation of the population. In England the population grows at the rate of 13 per 1000 every year; in Germany the rate is 10 per 1000; whilst the Americans have increased tenfold since the beginning of the century. At the present time France constitutes the tenth part of the population of Europe, whilst two centuries ago it represented a third. If this numerical deterioration continue, the French people will number at the beginning of the next century only a fifteenth of the European population, and will fall into the position of the small States, and be no longer recognisable as one of the Powers. When the population of a country begins to decrease, we must suppose either that there is an excessive mortality, or else that the birth-rate is diminished. Now, the death-rate in France is asserted to be even lower than that of the majority of European countries or States; consequently the comparative depopulation of France must be due to decrease in the number of births. In that country the number of infants in proportion to adults is less than in any other European nation, excepting Ireland. M. Lunier accepted M. Rochard's principal proposition, that the progressive diminution of the rate of increase of the population was the outcome of a voluntary abatement of fecundity to be observed in all classes of society. He averred that abortion is very commonly practised in England and America; whilst in France "un avortement en quelque sorte primitif" is also much in vogue, for in certain parts the chemists supply what are known as "pessaires de fond," which are vaunted as effective preventives of conception. This practice is said to have augmented the number of uterine affections. It is asserted that in France a relation pertains between the number of stillbirths and that of infanticides. Many infants declared to be stillborn probably die after birth. The number of known cases of infanticide is certainly not less than 7000 to 8000 a year, and it is probable that a fiftieth of all cases of stillbirth are cases of infanticide. M. Le Fort, in his remarks on this question, said that the number of illegitimate births had largely increased, not only in France, but in all Europe. In London the number of illegitimate children amounts to 5 per cent. of the total number of children born in wedlock.

CYSTINURIA.

IT has been recently pointed out by Lépine and Guérin (*Comptes Rendus*) that there exists in the urine two forms of sulphur, apart from that which appears in combination with bases as sulphuric acid—viz., one that is easily oxidised, and a sulphur that is difficult to oxidise. The former can be oxidised by means of chlorine or bromine, whilst the latter requires fusion with potassium nitrate and hydrochloric acid. The greater portion of that difficult to oxidise is apparently derived from the bile by the reabsorption of taurocholic acid, but evidently not the whole of it; for when a dog with a complete biliary fistula was fed with bread and fat, the sulphur oxidised with difficulty amounted to 20 per cent. of the whole sulphur, and with horseflesh to 25 per cent. Moreover, it is shown that sulphur difficult to oxidise is present in many pathological conditions in which there is no reason to suppose that bile was reabsorbed. It would have been a matter of interest if MM. Lépine and Guérin had stated whether in these cases the amount of urea excreted was also diminished. In cystinuria, in which a considerable amount of unoxidised sulphur is discharged as cystin, the urea is nearly invariably diminished, pointing to deficient oxidation, and as some disorder of the hepatic function is generally found to exist, it has been considered that the seat of the impaired metabolism was in the liver. In fact, it has been stated that a small quantity of taurin is eliminated by the kidney in health (hence the trace of unoxidised sulphur originally discovered by Ronalds in healthy urine), but that under certain conditions this is increased, and cystin is the result. The observations of MM. Lépine and Guérin, however, make it probable that we shall have to extend our hypothesis, and to conclude that mere increase of taurin does not lead directly to cystin, but to an increase merely of the unoxidised sulphur, and that some other condition is required to cause the appearance of cystin in the urine. This condition will probably be found to exist in defective elimination by the kidneys. In ordinary cases the taurin, whether in normal or excessive quantities, reaches the kidneys and undergoes transformation into unoxidised sulphur and urea. If, however, there is disorder of the kidney function, the transformation is only incompletely carried out, so that the intermediate product, cystin, is the result. This supposition is strengthened by the fact that cystinuria is frequently met with in patients whose kidneys after death have been found to have undergone extensive disorganisation. The therapeutic considerations to be drawn from these remarks are that in cases where we may be led to suspect the presence of cystin in urine, and fail to find it, we should pursue our inquiries a little further, and endeavour to ascertain the amount of unoxidised sulphur eliminated by the kidneys. If this should be increased, as these observations of Lépine and Guérin show it not infrequently to be, our treatment should obviously be directed to promoting general and local oxidation.

MR. JUSTICE HAWKINS ON "INSANITY."

IT is satisfactory to find a representative judge like Mr. Justice Hawkins acknowledging that the rule laid down in connexion with the MacNaughten case—namely, that to constitute *insanity* in a legal sense, the doer of a wrong act must either be ignorant of its wrongfulness or unconscious of the act itself—is defective. This has long been evident to everyone except Her Majesty's judges. The candour rather than the astuteness of Mr. Justice Hawkins is therefore to be commended, on the score of the admission he made recently in his charge to the grand jury at Shrewsbury. We do not suppose anything will come of the admission, but it is satisfactory to have it made. Sooner or later there must needs be a complete reversal of the mode of procedure in reference to the adjudication of insanity. The state of the subject must be determined on medical grounds, instead of being decided, as is at present too often the case, by the nature of his conduct. A sane man may perform actions which have all the qualities of madness impressed upon them, and a madman may act with perfect reason and purpose. The question of responsibility growing out of the allegation of insanity is, in our judgment, an issue which needs to be placed on an entirely new footing. Mr. Baron Huddleston is right in his opinion, that not every person of unsound mind should be excused from the necessity of acting lawfully. There are, as Dr. Edgar Sheppard pointed out years ago, many cases in which a minimum of insanity is accompanied by a maximum of vice and criminality. Those who are struggling to have *every* subject of mental disease classed as irresponsible are doing much to facilitate the commission of crime. The insane—

so-called are, as a rule, quite cunning enough to perceive the advantages of their assumed "irresponsibility." Those who have any practical knowledge of the inmates of asylums must be well aware that many presume and encourage each other to do wrong on the ground that they cannot be legally punished. We shall be glad when this subject comes to be discussed fairly, by competent judges, on a full and clear basis. Mr. Justice Hawkins is of opinion that one attendant is not a sufficient custodian for some sixteen or seventeen "dangerous" lunatics. We entirely agree with him.

GENERAL GORDON.

IT is still, at the moment of our going to press, premature to assume the fate of General Gordon. Hopeless as the chance seems to be, he may have escaped up the Blue Nile on board one of the three steamers he is known to have possessed, but which are now missing. If Gordon, with his accustomed acumen, suspected the betrayal of the city by the pashas he had trusted, the discovery of their infidelity would, of course, relieve even his high sense of honour from the obligation of remaining at his post; and it is possible, if not probable, that he put into execution one of the two schemes he is known to have formed long ago for retirement from Khartoum in the event of a great emergency. We must wait with what patience we can command for the *dénouement* of one of the most tangled and miserable plots in British history. Nearly a year ago it would have been easy to do all that can be accomplished to-day at less than one tithe the cost, and with the certainty of rescuing the man in whose fate this country is mainly interested. Then Colonel Stewart would have been saved, and thousands of wasted lives spared to the service of a State which has not too many earnest and able defenders. It is the popular belief that the blunder, as it undoubtedly was, of not pushing on to the rescue of Gordon at that time was wholly and simply political, and that Mr. Gladstone and his colleagues are personally responsible for the mistake and its consequences. This is not the fact. It seems to be forgotten that at the moment when the question of advancing was in debate the Cabinet actually summoned Lord Wolseley to their Council and conferred with him. This was a most unusual course to take. It was certainly not the act of men who had a dogged determination to pursue a policy of their own. It was clearly an endeavour to obtain the best available advice under the circumstances. Unless it can be shown that Mr. Gladstone and his colleagues acted directly in opposition to the opinion of the military authority they had consulted in determining to allow General Graham to advance, it is fair to assume that the policy pursued on that occasion and since has not been so fatuous as the thick-and-thin opponents of Mr. Gladstone and his Government describe it. We would suggest that common justice compels the recollection of this strangely forgotten fact of Lord Wolseley's attendance at the councils, for that fact clearly cuts the ground from under the feet of many a carping critic who is now full of reproach for the political, while fulsome in his adulation of the military chief.

TRAINED NURSES' ANNUITY FUND.

THE Trained Nurses' Annuity Fund was founded in 1874; and its object, as stated in the prospectus issued by the committee, is to give a good-service pension of £15 per annum to superannuated or broken-down trained nurses who have served three years in a hospital and at least fifteen years as private nurses. Considering the wear and tear upon their constitution from disturbed rest, vitiated air, and the anxiety inseparable from their vocation, nurses are as a class extremely badly paid; and, as a rule, when they break down they are unfitted for other employment. The existence of such a fund as this, therefore, so far from pauperising, is frequently the means of enabling respectable women, who have worked hard and usefully, to spend the remainder of their lives in comfort with their friends or relations, whereas without it they would have no resource but the workhouse. Eleven annuities have been founded: ten paid from the interest of invested funds, and one from the annual subscriptions. The constant applications which the council receive from those eligible to share in the benefits of the institution have impelled them to appeal for further help, in the confident assurance that their appeal will not be in vain, but that the more the fund is known the larger will become the number of its supporters.

MEDICAL MISSIONS.

WE would fain extend and deepen the interest of the profession and the public in the support of medical missions. Imagination and experience alike help us to understand the important part which medicine is likely to play in conciliating the heathen of all countries and disposing them favourably towards Christianity. From the time of our Saviour downwards men have been lured to Him often in the first instance by the desire for physical benefits, notably for the cure of disease. The blind and the deaf, the halt and the maimed flocked to Him, while those who were in the pride of health kept away. It is so now in heathen countries. The "gifts of healing" are among the best gifts that the church can use in seeking the advantage or the conversion of the backward nations. The report of the Edinburgh Medical Missionary Society for 1884 will satisfy doubters as to the advantage of a medical missionary in every large missionary station. It seems to us that the great missionary societies have not yet fully realised these advantages. We have lately seen it stated by a good authority that the Church Missionary Society, for some reason or other, has not made full use of this great ministry. We feel persuaded that such a criticism will receive the attention of the authorities of this great society and be taken kindly by them. In the report to which we have alluded it is painful to see that after the formal consent of the Turkish authorities for building a new hospital at Nazareth various obstacles have been raised which seem to have little other meaning than a desire to exact "backsheesh." In the meantime lithotomies and other serious cases treated by Dr. Vartan have to be housed in what is little more than a temporary shed. This is a matter in which our Foreign Office might and ought to make its influence felt. We trust that our readers and their children will devote some of their missionary subscriptions either to the Edinburgh Medical Missionary Society, which has had the support of such men as Abercrombie, Alison, and Coldstream, or to other societies which employ the best medical servants they can obtain.

A CORONER ON DELIRIUM TREMENS.

A CORRESPONDENT writes:—The coroner for the West Derby District has recently held an inquest on a man who died from inflammation of the lungs and delirium tremens. The man and his friends failed to get medical advice until the day he died, when on that day he, along with his wife, visited the local medical man, who saw the danger he was in, and advised him to get home as soon as possible. The poor man died as soon as he reached the house. The medical man, having seen him only once, and the man dying under the circumstances, decided not to give a certificate of death until the coroner had inquired as to the necessity of an inquest. An inquest was held, and the coroner, following the remark of a juryman, did not know why the doctor had not certified. This was after the doctor's evidence; but he

added, delirium tremens is an alcoholic blood poisoning, and this was the reason he had determined to hold an inquiry. He thought in cases of delirium tremens it was the duty of the medical attendant not to certify, but communicate with the coroner of the district. This is a new reason for an inquest, and if this view be correct, inquests must be increased manifold. Inquests have been understood to be necessary in cases of sudden death or where there was any suspicion, not in cases of blood poisoning by alcohol, unless there was reason to believe some one had poisoned the deceased, or the deceased had taken the poisonous fluid with the intention of destroying life. In a case like this one the reason was manifest. There might have been neglect on the part of friends in not applying for medical aid, or there might have been injudicious treatment on his arrival home.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

IN resuming our notice (see p. 312) of the annual and special reports of medical officers of health by comment on some of those which have reached us and which relate to the year 1884, we would point out how great is the advantage which attaches to the early preparation and issue of all annual reports. Some of them are hardly ever issued before the closing months, or even weeks, of the years following those to which they relate, and by that time much of the value which an early issue would have ensured for them has become lost, and nearly all interest in the matters they deal with has often passed away. An excuse is sometimes made that the preparation of statistics for large and multiple districts combined with the delay in printing necessarily causes considerable delay. With regard to this, we would point out that the reports for 1884 on which we comment on to-day are all printed documents; that one of them covers some forty pages, deals with a number of sanitary districts, and contains numerous tables, &c. which go to show that a considerable amount of time and labour must have been devoted to the compilation of statistical information; and also that all the reports were received by us before the expiration of the month of January. The official instructions to medical officers of health specially press upon them the desirability of making their reports as soon as possible after the expiration of the period with which they deal, and, as the result of our experience as to the reports forwarded to us, we are quite unable to see that any of them contain matter which justifies their being delayed beyond the first three months of the year.

THE RESULTS OF SPLENECTOMY IN THE RABBIT.

PROFESSOR GUIDO TIZZONI has experimented on this point, and remarks that after the operation of removal of the spleen in man, Crédé observed enlargement of the thyroid, an observation that led various experimenters alternately to deny and affirm the existence of functional relations between the two organs. Tizzoni satisfied himself that no such relation existed in the dog, and his present series of experiments were undertaken to determine whether it existed in the rabbit. The operation is more difficult to perform in the rabbit than in the dog. Eighteen rabbits were operated on and killed at intervals varying from 12 to 240 days. At the autopsy the epiploon, the red marrow of the bones, the thyroid and the thymus were examined with care histologically, partly whilst quite fresh, partly after the use of hardening agents. He arrived at the following conclusions:—Splenectomy practised on the rabbit produces no appreciable effect on the general health of the animal. The age of the animal is without influence on the results of the operation; no difference is observed in the condition of the animal after ablation of the spleen either in its general condition, its digestion, power of growth, or of assimilation. It exercises no influence on its fecundation or powers of reproduction. The young produced are perfectly sound and healthy, contrary to that which takes place in dogs. Splenectomy in rabbits does not cause any perceptible modification in the hæmatopoietic tissues and organs; no reproduction of the spleen takes place in the great omentum or other folds of the peritoneum. In old animals no alteration is observable in the marrow of the bones; it is only in young animals that a somewhat greater number than usual of red corpuscles and of the caryokinetic figures, indicating indirect nuclear fission, is visible. The thymus and thyroid appear to be unaffected by ablation of the spleen; it does not appear to influence in any way the involution and disappearance of the thymus, nor to effect any modification of the volume or structure of the thyroid. From all of this Professor Tizzoni concludes that the question of hæmatopoiesis ought to be studied separately in each species, and that results obtained from experiments conducted on any one species should not be regarded as applicable to all.

LUCELLE DUDLEY.

O'DONOVAN ROSSA having survived the desperate wounds he received from the bullets or bullet fired by the woman Dudley, and that worthy man having magnanimously intimated his intention not to prosecute his assailant, it is probable that no great difficulty will arise in the liberation of the prisoner. Looking at the matter from a general and public point of view this may be satisfactory; but there is another standpoint, and from that it certainly appears to be a matter of some moment that the future of this excitable female should be provided for. We do not affirm that it would be necessary, or even justifiable, to send her back to the asylum life from which she has been once liberated, but seeing that the story of her life is full of the most conclusive evidence of mental disease, with both suicidal and homicidal tendencies, it is manifest that she should be protected, and that society should be protected from her morbid impulses. We yield to none in the abhorrence of the victim of Mrs. Dudley's impulse, but we cannot on this account disguise the fact that she is neither more nor less than a person of unsound mind. It is nothing to the point that her utterances may be perfectly coherent, and the account she gives of herself entirely rational. The most dangerous lunatics are those who, while insane on some one point, or subject to impulses of violence, do not present, and, as matter of fact, do not possess, any morbid feature, except that which renders them dangerous to themselves or those about them, or, as would seem to be the case with Mrs. Dudley, to both. The method in madness is its worst feature. What Dr. Prichard called "moral insanity" is one of the most mischievous forms of mental disease, and, unfortunately, the most incurable. Like the man-eating tiger, a lunatic who has once committed an act of homicide is for ever afterwards dangerous. It matters nothing to the issue that, in this instance, the lunatic was excited to violence by the villany of her victim. What she did was an act of insanity. Had she been even a little less insane than she has shown herself, the bare facts that on more than one occasion she had attempted to commit suicide and that she had been in an asylum would have deterred her from regarding herself a fit instrument of public vengeance. The assumption of such a character by such a person is in itself conclusive evidence of unsoundness of mind. This is the view we are compelled to take of the mental condition and deeds of the woman of whom some unthinking or emotional folk are trying to make a heroine, if not a martyr. It is eminently desirable to put a stop at once to mistakes of this character. Nothing is less likely to serve the cause of

peace and safety in civilised society than turbulent emotion, whether the occasion of its outpouring be fear or gladness. If this woman be arraigned for her crime, it will be a duty to prove her irresponsibility, by showing that she has been and still is a fit subject for restraint in an asylum. That is the simple fact, and there is really no more to be said on the subject than that those who are concerned in the case must do their duty. Mrs. Dudley cannot be hanged, not because the deed was not worthy of hanging, but because she was a lunatic. The evidence of insanity in this case existed anterior to the commission of the offence she has committed; and the only serious question is, why a lunatic with destructive tendencies was let loose from salutary control?

A NEW METHOD OF TREATING ACUTE INTESTINAL OBSTRUCTION.

THERE has recently been advocated and successfully practised a method of affording relief in cases of intestinal obstruction, which may become widely applied. Dr. Kussmaul was the first to advance the view that free washing out of the stomach might prove efficacious, and already cases of marked success following this measure have been published. In one case, after eight days' complete obstruction, and in the other, after nine days, the symptom of fæcal vomiting being present in each, the washing out of the stomach, and consequent evacuation of large quantities of fluid fæcal matter from the upper part of the small intestine, resulted in complete relief from symptoms. The measure is compared by Cahn (*Berl. Klin. Woch.*, 1884, No. 42) to the effect produced by laparotomy above the site of an obstruction; and the good result is explained on the ground that the evacuation of the distended bowel affords an opportunity for a spontaneous reduction of a herniated or twisted loop. The relief from the inordinate abdominal distension is very great, and, moreover, the disappearance of this distension favours palpation for the purpose of diagnosis. Obviously, not every case of acute intestinal obstruction could possibly be relieved by this method, but the simplicity of the practice, the certainty of affording temporary relief, and the possibility of a cure are reasons for its sedulous adoption prior to proceeding to more serious measures.

SMALL-POX IN LONDON AND THE PROVINCES.

IN his last monthly report Dr. Dudfield states that twenty-four cases of small-pox have occurred in Kensington, nineteen of these being in South Kensington. Their relation to the area in which the small-pox hospital is situated is not stated. The epidemic as a whole shows no signs of abatement. On Jan. 3rd there were 1013 cases under treatment in the hospitals of the Asylums Board, on the 31st the number had risen to 1147, and on February 7th it was 1144. Some real difficulties are experienced in getting patients removed to private hospitals, such as that at Highgate, and Dr. Dudfield has urged upon the managers of the Asylums Board to undertake this duty. As yet they do not see their way to extend their operations in this direction, but we can hardly doubt that in time that Board will become the ambulance authority for the whole of the metropolis. Small-pox is also showing a tendency to break out in different parts of the country. Thus, near Banbury, one of the headquarters of the anti-vaccination party, cases are somewhat numerous, round about Taunton and Bridgewater the disease is prevalent, and several minor outbreaks have occurred. So far they appear to have been successfully met by vaccination, but we would warn vaccination authorities to be on the alert, for extension to the provinces is the ordinary sequel to a metropolitan prevalence.

THE LATE SIR THOMAS NELSON.

JUST before the Beaconsfield Ministry retired, we took occasion to point out that in their distribution of honours they had forgotten to recognise the great and most useful services of the man to whom, mainly, the people of London owed the preservation of Epping Forest and many other lasting benefits. The remonstrance we ventured to address to the advisers of the Queen on that occasion was, as we had reason to know, taken in good part, and immediately acted upon. The omission was repaired; and Mr. Nelson, the City Solicitor, to whose earnest endeavours for the public good so much was due, received the honour of knighthood, not as a mere routine compliment to the civic position he held, but as a gracious recognition of his personal merits and services. The gratification we experienced on that occasion is now merged in deep regret for the untimely death of Sir Thomas James Nelson, who expired after an attack of subacute gout, from which he appeared to be recovering, on the morning of Saturday last. By a large circle of personal friends, and by all who know the extent to which the people of London owe the preservation of Epping Forest to his enterprise and painstaking industry, Sir Thomas James Nelson will be long and lovingly remembered.

INCREASE OF REMUNERATION OF MEDICAL OFFICERS OF PROVIDENT DISPENSARIES.

WE are glad to notice that at the Reading Medical Dispensary a resolution has been passed to increase the payments of provident members of the dispensary, and so to give more adequate remuneration to the medical officers for the enormous amount of work they do. The attendances in 1884 have been 112,804, in place of 91,589 in 1883. We are not told what the medical men are paid for this great labour, but unless Reading is different from other places it is far below what they ought to be paid. The resolution passed was as follows:—

"To substitute the following Clause, in lieu of Clause 2 in Rule 17. 'Every member (except as undermentioned) shall pay one penny per week. For families, the payment shall be twopence per week, which sum shall include a man, his wife, and all his children under twelve years of age, and in the cases of widows and their children the payment shall be three-halfpence per week. The wives of members of a friendly society, with their children under twelve years of age, shall be eligible to become members at a sum of twopence per week, but such sum shall also include the husband if he elects to become a member. Applicants for membership after the 28th day of February, 1885, who shall exceed the age of fifty at the date of their application, and also any persons who shall be certified by their medical attendant to be suffering from chronic or incurable ailments, within one month from the date of their admission as members shall pay one penny per week extra, in addition to the payments above provided.'"

SANITARY CONDITION OF MARKET WEIGHTON.

MARKET WEIGHTON is an agricultural town in Yorkshire, and has since last September been invaded by an epidemic of enteric fever. Amongst a comparatively small population there have been seventy-four cases, and probably many others that have not come under the notice of the medical profession. A more insanitary town it would probably be difficult to find; scarcely a year passes that it is not the scene of some kind of epidemic; the population is consequently diminishing. The town is of great antiquity, and is placed on a thin layer of sand and gravel, in a basin of blue clay. The wells are shallow, and usually close to the cesspools and sewers, the latter being very old, and imperfectly constructed of bricks. The great drought of last

year caused the drinking-water to be much more highly charged with impurities than usual. This outbreak of fever followed closely on a similar one at the town of Beverley, about ten miles distant, and from there probably the infection was imported. The fever is of an unusually mild type. The Local Government inspector spent nearly a week at Market Weighton investigating the cause of this epidemic, devising means for limiting its spread, and for its prevention in the future, the result being that the town will shortly be supplied with pure water by a waterworks company, and that the rural sanitary authority will at once commence a new and complete system of drainage for the town.

OBSTETRICAL SOCIETY.

THE annual meeting of this Society took place on Wednesday last. The retiring President, Dr. Gervis, delivered the annual address, which will be found elsewhere. The vote of thanks to the retiring President was proposed by Dr. Graily Hewitt and seconded by Dr. Playfair in cordial terms, allusion being specially made to the courtesy and impartiality displayed by Dr. Gervis. The Society numbers more subscribing members than any other Medical Society, and its continued and even increased vitality is marked by a large increase in the total of papers contributed, as well as by a steady growth in the number of its Fellows. The list of officers and councillors proposed by the Council was carried by the meeting, which was a full one.

THE REMOVAL OF STRYCHNINE FROM THE ORGANISM.

PROFESSOR DRAGENDORFF (in a Russian medical journal) has lately published the results of experiments bearing upon the above subject, and carried out at his suggestion and under his guidance by P. von Rautenfeld upon men and animals. These results fail to confirm Plugge's conjecture, that strychnine is oxidised in the organism. It is stated that it is removed in an unchanged condition by means of the urine, this process taking place within a short time of the poison being taken. It is, however, considered probable that the liver for the most part retains the strychnine, only giving it off in small quantities.

THE FATAL BAYONET WOUND AT WOOLWICH.

AT the inquest held on the body of the unfortunate practical joker who was killed by his comrade in the strict exercise of his duty at the Woolwich magazine, the corporal showed, by request of the coroner, the exact position of the bayonet at the charge, pointing to a man's breast; and Surgeon Dodd, who made the post-mortem examination, stated that the weapon had penetrated about six inches, piercing the heart and the right lung.

DRUNK AND DYING.

AT an inquest held last week by Dr. Danford Thomas on the body of Annie Robinson, aged thirty-two, it was stated by the inspector of police that deceased was admitted into the police-station in a state of intoxication, and that he did not send for a doctor "as he knew it was a case of drunkenness." She was kept at the station in a state of insensibility for twelve hours before being sent to the infirmary. When, however, she was admitted to St. Pancras Workhouse, she was found by the medical officer to be "in a most horrible condition; and she had a scalp wound, and another on her hand. Erysipelas set in, and she died." It is far too readily supposed by the police and others that because a person is drunk he cannot require medical assistance; the fact being that, as in this case, a slight wound is much more likely to prove fatal in a drunkard than in a sober subject, and therefore specially requires prompt skilled attention. The Metropolitan Police Regulations provide for such cases as follows:—

"If prisoners are insensible, or appear to be ill or injured in any way, although they do not complain, the divisional surgeon is to be sent for immediately. This course relieves the police of responsibility, and is to be strictly observed. The Commissioner desires to impress most earnestly on the police the heavy responsibilities which they incur by deviation from this regulation, and to warn them that in every instance of wilful disobedience and neglect the officer will be visited with the severest punishment." (Prisoners, sec. 34.) And again: "In every case where a person is brought to a station in a state of insensibility, whether supposed from drink or any other cause, the officer on duty at the station is to send for medical advice as soon as possible." (Drunken Persons, sec. 7.)

There would appear therefore to be no excuse for leaving a drunken prisoner in the condition in which deceased was without sending for a surgeon. Had this been done at once the fatal result might have been averted.

IN response to a letter addressed to him by the committee of the Sunday Society respecting the proposed opening on Sundays of the Natural History Department of the British Museum, and requesting him to receive a deputation on the subject, Mr. Gladstone has replied that, having regard to the demands which the business of his office make upon his time and attention, he is unable to accede to the wishes of the committee.

WE understand that the *Quarterly Journal of Microscopy and Natural Science* will, in future, be published by Messrs. Baillière, Tindall, and Cox. This Journal, which is the official organ of the Postal Microscopical Society, has been enlarged, but the price will remain as heretofore (1*s.* 6*d.* per quarter). Mr. Alfred Allen will continue to edit the publication on behalf of the Society.

IT is stated that Dr. Green, who was appointed Vice-President of the Sanitary Board at Alexandria in succession to Dr. Sandwith, who was compelled to resign his office owing to the intrigues of his native superior, is likely to tender his resignation for the same reason as his predecessor.

IT is announced that Mr. Thomas Brock, A.R.A., has finished a marble bust of the late Sir Erasmus Wilson on a commission from Lady Wilson, and that he is also well advanced with a statue of the late Sir Erasmus, which is to be placed outside the Sea-bathing Infirmary at Margate.

THE death is announced, in his sixty-third year, of Surgeon-General Thomas C. O'Leary. He entered the service in 1847, and served with the 68th Light Infantry at the siege and fall of Sebastopol, receiving the Crimean and Turkish medals and the fifth Class of the Order of the Medjidieh.

NEARLY 5000 vaccination defaulters at Leicester are about to be prosecuted by order of the Local Government Board. The requisite notices and summonses which will have to be served will amount to 20,000.

THE Maharajah of Cashmere is said to be dying of nephritis. Visitors to the valley occasionally saw him when he was in good health, and many have partaken of his Highness's hospitality.

MR. BRYANT will deliver his inaugural address at the Clinical Society to-night (Friday).

WE learn that at the examinations which began on Monday last at the London University for appointments in the Military, Naval, and Indian Medical Services, eighty-six candidates presented themselves for competition for thirty-two vacancies in the Army Medical Staff, nineteen for five appointments in the Indian Service, and sixteen for eight in the Royal Navy.

DR. K. B. STUART, for many years Coroner of Calcutta, died in that city of Bright's disease on December 14th. Dr. Stuart was a M.D. of St. Andrews, a F.R.C.S. Edinburgh, and a Fellow of the Calcutta University.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Herefordshire Combination.—Dr. Sandford's annual report for 1884, on the combined urban and rural sanitary districts in the county of Hereford, is now issued, and it consists in the main of a series of separate reports to the several authorities concerned. As regards Hereford city, Dr. Sandford strongly urges the provision of means of isolation, and, writing on January 11th, he reminds the authority that small-pox was then prevalent in the district. He also urges upon them a stricter system of inspection as to diseased animals which are slaughtered, dressed for the food of man, and then brought into the city for sale. The general death-rate for the city was 18·3 per 1000, and the district was exceptionally free from any prevalence of dangerous infectious diseases. Into the Bromyard rural district small-pox was imported by hop-pickers. The patient, a woman, had five children with her, and under the circumstances a cottage was taken as a hospital, and to it both she and the children were removed, a nurse being hired to wait on them. By the aid of this isolation, together with vaccination, no spread occurred beyond the first case. Some of the separate reports consist mainly of statistical matter, with a mere enumeration of the current diseases. Perhaps it may be taken for granted that no sanitary works of improvement are needed in these cases, and hence the absence of any reference to the subject.

Torquay Urban District.—As the result of a house-to-house inspection during 1884 the few cases of real over-crowding in Torquay have been done away with, and it is proposed that at definite periods similar detailed inspections of special districts shall be undertaken. Such systematic work is of the highest value. Mr. Karkeek reports a great improvement in the arrangements for the water-supply of the town; a new reservoir has been constructed, and the prospect of an insufficient supply to meet the steadily increasing demands is now put off to a very remote date. The death-rate was 15·4 per 1000, but excluding the deaths of genuine visitors, it only reached 13·5 per 1000, and this in the case of an urban population of some 26,000. The only death from enteric fever occurred in a French sailor, who died within twenty-four hours of landing.

Marychurch Urban District.—This district is also within the area for which Mr. Karkeek acts as medical officer of health. Although the death-rate has been as low as 13·6 per 1000, and although the sanitary experience of the past twelve months has on the whole been exceedingly satisfactory, yet it is pointed out that, owing to the recurring importation of infectious diseases, the past year was one of considerable anxiety. Fortunately the main disease imported was small-pox, which is rarely secreted in country districts, and one of which vaccination affords a ready means of prevention. But had it been otherwise the need for some isolation arrangements would have been very urgent, and the report reminds the authority that this matter has before now been brought under their notice.

Gloucestershire Combined District.—Dr. Bond has submitted his eleventh annual report, for 1883, to the authorities of the eight rural and the five urban districts which form his combination. The birth-rate shows a tendency to fall, and is now only 28·5 per 1000, the death-rate stands at 17·5, and that for the principal zymotic diseases at 1·5 per 1000. Dr. Bond groups scarlatina, diphtheria, and croup under one head as scarlatinoid; scarlatina caused 78 deaths in 1883, diphtheria and croup causing 23 deaths. The diminution in the latter diseases, whilst the scarlatina has remained very prevalent, is contrary to Dr. Bond's previous experience, which has hitherto gone to show that an increase in the more diffusive of these two types of disease has always brought with it an increase also of the other. The deaths from fever number 24, which is six below the mean of the last ten years. One serious fever outbreak took place in the Watermoor district of the town of Cirencester, and was connected with a stoppage of one of the town sewers. In this case some forty attacks took place, eight deaths resulting during the year. The first cases were mild, and hence a considerable number had occurred before they were detected and removal to the infectious hospital could be carried out. The cause was the forcing by children of stones through a street ventilator, which resulted in a blockage of sewer contents and the fouling of wells and houses by soakage of filth and sewer emanations. The hospital was eminently useful on this occasion, and it is impossible to judge of the extension of disease which would have taken place had it not existed. Unfortunately, Cirencester is the only place in the combined district where hospital accommodation is available. As regards sanitary works, progress is being made by the borough and rural authority jointly as to sewer extensions into the Gloucester rural district; the sewer ventilation of Cirencester is being improved, and an excellent water-supply for the town is being provided. Considerable efforts have been made to secure combined action between the Gloucester urban and rural districts in the matter of hospital provision, according to a plan advocated by Dr. Thorne Thorne, of the Local Government Board. The difficulty seems to lie with the urban authority, who, having a very imperfect wooden structure which has been all but useless, propose making some alterations in it and resting content. This action is entirely opposed to the wishes of the majority of the medical profession in the city, and any step taken under such circumstances cannot be expected to produce the result desired—namely, the prevention of the spread of infection by early isolation.

Salford.—Considerable sanitary progress has during the last few years been made in the borough of Salford. The sewers have been materially improved, the dwellings of the poorer classes are steadily becoming better, scavenging arrangements have been considerably modified, a destructor has been erected, the infectious hospital has been enlarged, a steam disinfector has been provided, and public baths and open parks have been secured. The compulsory notification of infectious diseases has also been brought into operation, and Dr. Tatham takes an opportunity of acknowledging the uniform and prompt assistance which the medical profession have rendered him under the newly acquired powers. During the year 1883 as many as 365 cases of infectious diseases were admitted into the Wilton Hospital, including 14 cases of typhus which occurred in September and October. Unfortunately, the Wilton Hospital is, even now, not all that can be desired from a constructive point of view, and small-pox cannot be received on the premises. Cases of this disease are hence sent to Monsall Hospital. A permanent staff of inspectors is constantly engaged in endeavouring to prevent the spread of infection directly the cases are heard of, and under Dr. Tatham's superintendence the sanitary defects which are discovered are remedied and disinfection is largely carried out. The population of Salford is now 190,455, and the death-rate per 1000 during 1883 was 22·5, the lowest rate for eighteen years, except that for 1881, which stood at the same figure. The infantile mortality, though diminishing, is still high, and it is much to be feared that insurances effected in provident societies tend to increase it. Like all Dr. Tatham's reports, that for 1883 is very exhaustive and contains matter of much interest.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 6312 births and 3714 deaths were registered during the week ending the 7th inst. The annual death-rate in these towns, which had ranged between 24·0 and 24·9 per 1000 in the first four weeks of this year, fell to 21·8 in the week ending the 7th

inst. During the first five weeks of the current quarter the death-rate in these towns averaged 23·9 per 1000, against 24·5, the mean rate in the corresponding periods of the five years 1880-84. The lowest rates in these towns last week were 15·1 in Birkenhead, 16·2 in Blackburn, 16·6 in Salford, and 16·7 in Sheffield. The rates in the other towns ranged upwards to 27·5 in Norwich, 29·1 in Manchester, 30·4 in Bristol, and again, the highest, 32·2 in Preston. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 372 and 396 in the preceding two weeks, declined to 356 in the week ending last Saturday; these included 104 from whooping-cough, 53 from measles, 53 from scarlet fever, 46 from small-pox, 37 from diphtheria, 34 from "fever" (principally enteric), and 29 from diarrhœa. The lowest death-rates from these diseases, in the aggregate, were recorded last week in Oldham and Blackburn, and the highest in Cardiff and in Sunderland. Whooping-cough caused the greatest mortality in Bristol and Preston, measles in Cardiff and Sunderland, scarlet fever in Sunderland and Wolverhampton, and "fever" in Hull, Cardiff, Plymouth, and Norwich. The 37 deaths from diphtheria in the twenty-eight towns included 19 in London, 3 in Birmingham and in Liverpool, and 2 in Manchester and in Newcastle-upon-Tyne. Small-pox caused 63 deaths in London and its outer ring of suburban districts, 3 in Birmingham, 1 in Liverpool, and 1 in Cardiff. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which had been 1009, 1092, and 1146 on the preceding three Saturdays, were 1144 at the end of last week; the admissions further declined to 223 last week, from 287 and 253 in the previous two weeks. The Highgate Small-pox Hospital contained 99 patients on Saturday last, 14 cases having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had ranged between 609 and 513 in the preceding four weeks, fell to 421 last week, and were so many as 226 below the corrected weekly average. The causes of 81, or 2·2 per cent., of the deaths in the *twenty-eight* towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Brighton, Leicester, Nottingham, and in three other smaller towns. The largest proportions of uncertified deaths were registered in Hull, Halifax, and Leeds.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been equal to 28·5 and 30·2 per 1000 in the preceding two weeks, declined to 26·6 in the week ending the 7th inst., but exceeded by 4·8 the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 14·9 and 19·9 in Perth and Edinburgh, to 33·0 in Dundee and 33·4 in Paisley. The 649 deaths in the eight towns included 34 which were referred to whooping-cough, 24 to measles, 10 to diarrhœa, 9 to scarlet fever, 8 to diphtheria, 6 to "fever" (typhus, enteric, or simple), and 1 to small-pox; in all, 92 deaths resulted from these principal zymotic diseases, against 85 and 98 in the preceding two weeks. The deaths attributed to acute diseases of the respiratory organs in the eight towns numbered 189.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 31·9, 31·9, and 35·5 per 1000 in the preceding three weeks, further rose to 36·2 in the week ending the 7th inst. During the first five weeks of the current quarter the death-rate in the city averaged 33·2 per 1000, against 23·2 in London and 22·5 in Edinburgh during the same period. The 245 deaths in Dublin last week showed a further increase of 5 upon the numbers returned in recent weeks, and included 18 which were referred to the principal zymotic diseases, against 23 and 22 in the preceding two weeks. Of these 18 deaths, 5 resulted from scarlet fever, 5 from measles, 4 from "fever," 1 from whooping-cough, 1 from diarrhœa, and not one from small-pox. These deaths were equal to an annual rate of 2·7 per 1000, the rate from the same diseases last week being 1·9 in London and 2·7 in Edinburgh. The fatal cases both of measles and of scarlet fever exceeded the numbers returned in recent weeks, while those of "fever" showed a decline of 5 from the number in the previous week. Three inquest cases and 3 deaths from violence were registered within the city; and 70, or nearly a third, of the deaths were recorded in public institutions. The deaths of infants showed a further increase upon recent weekly numbers. The causes of 38, or nearly 16 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

THE ARMY MEDICAL SCHOOL.

Deputy Surgeon-General D. B. Smith, of the Indian Medical Department and of the Calcutta Medical College, has been selected for the appointment of Professor of Military Medicine at the Army Medical School at Netley, in succession to Inspector-General Maclean, who has relinquished that position.

CHANGE IN THE UNIFORM OF MEDICAL OFFICERS.

The scarlet tunic hitherto worn by medical officers is now changed for a blue one, ornamented with gold lace and braid. The cocked hat ceases to be worn by officers below the rank of brigade surgeon, except when employed at army headquarters or on the staff of a governor or general officer. It is replaced by a helmet of the home pattern, with the gilt ball in a leaf cup, and a helmet plate in gilt metal. Officers of the Militia Medical Staff will wear the same uniform as those of the Medical Staff, except that the letter M. will be worn below the badges of rank on the shoulder. Medical officers of Militia battalions who have not elected to serve on the departmental list, will continue to wear the uniform of their regiments, but with cocked hats, plumes, belts, and pouches, as for officers of corresponding rank in the Medical Staff. So few of the new uniforms are as yet in use that we have not heard many comments from the wearers. Some object on sentimental grounds to the change from the traditional scarlet of the main part of the British army. The patrol jacket, which is almost the same as that worn by veterinary officers, has been complained of because of the inconvenience of the heavy front loops, which are likely to get in the way during operations.

The following surgeons have been appointed to the Medical Staff Corps, and are now at the depôt and training school at Aldershot undergoing a course of instruction, which is being pushed forward as rapidly as possible, so that these officers may be speedily available for active service:—Surgeons J. R. Forrest, M. W. Russell, W. R. de Momini, B. F. Zimmerman, A. F. Stace, A. Stables, J. F. E. McGrath, E. A. C. Smith, G. E. Moffett, A. M. Hewson, H. A. Hawes, J. B. Moir, R. Crofts, F. M. Dobson, A. T. J. Lilly, R. Caldwell, A. C. Reilly, S. E. Duncan, J. Maher, A. Perry, H. W. James, R. Trevor, H. D. Innes, A. Turner, and B. O. W. Norton.

Orders were received at Woolwich on the 9th inst. by the Medical Staff to prepare medical stores for 10,000 men.

Assistant Commissary-General J. S. Young, who was despatched to Egypt in October last as special commissioner of the National Society for Aid to the Sick and Wounded in War in connexion with the Nile Expeditionary Force, has been fortunate in acquiring a steam launch which draws only 2ft. 6in. of water, and which can steam five to six miles an hour against the stream. The launch will ply on the Nile under the superintendence of Mr. Young, and under the medical charge of Mr. E. F. White, F.R.C.S., of St. Thomas's Hospital. The aid to be rendered will take the form of transporting on the upward journeys comforts for the use of patients in hospitals on the line of communications, and on the downward journeys conveying invalids, for whom there is every requisite provided on board.

Deputy Surgeon-General R. Wolseley, Sanitary Officer, Aldershot Division, has been appointed Principal Medical Officer, North British District, Edinburgh.

WAR OFFICE.—Army Medical Staff: Surgeon-Major James Henry Jeffcoat to be Brigade Surgeon, vice John George Faught, promoted; Surgeon-Major John Mackenzie, M.D., to be Brigade Surgeon, vice William Henry Muschamp, promoted; Surgeon-Major John Davidge to be Brigade Surgeon, vice Fitzgerald Edward Scanlan, granted retired pay; Surgeon-Major Samuel Archer to be Brigade Surgeon, vice Stewart Aaron Lithgow, promoted; Surgeon-Major Patrick Walter Stafford is granted retired pay, with the honorary rank of Brigade Surgeon.

INDIA OFFICE.—The Queen has approved of the promotion of Surgeon-Major James Ross, of the Madras Medical Establishment, to be Brigade Surgeon.

ADMIRALTY.—Dep.-Inspect.-General Edward S. Mortimer has been appointed to Haslar Hospital.

Correspondence.

"Audi alteram partem."

"CONGENITAL DISLOCATION OF THE HIP."

To the Editor of THE LANCET.

SIR,—In your issue of Feb. 7th Mr. Brodhurst takes me to task for my criticism of his published opinions on congenital dislocation of the hip, which formed part of my address in opening the session of the surgical section of the Academy of Medicine in Ireland.

With your permission I will reply to his attack. His first assault is on my competence to express an opinion on the subject because of my inexperience. "These are the cases on which Dr. Bennett founds his judgment"—namely, the recent dissection presented by me to the meeting, and the case published by Hutton in 1835. He has overlooked the fact that I exhibited at the meeting, beside my own dissections (two cases), four examples dissected and preserved by Harrison. The pathological verity of these specimens is vouched by the names of Hutton, Harrison, Adams, and R. W. Smith. My own cases agree in every detail with them. May I ask how often has Mr. Brodhurst dissected the deformity? I have dissected it twice with before me the specimens and experience acquired by my predecessors in office, but apparently Mr. Brodhurst will not permit me the right to form an independent judgment because of his overwhelming knowledge derived from "forty cases under his care." He says of these cases; "So far as I have been able to learn, with one exception only, all occurred in preternatural labours. The other was the result of violence immediately after birth." We may put aside "the other," for it has no right to a place among congenital dislocations, except it be to swell Mr. Brodhurst's cases to the round number forty. "So far as I have been able to learn" is poor evidence on which to make the positive assertion: "This dislocation never occurs except with preternatural labour, and it occurs especially with presentation of the nates." In my address I quoted this passage, and met it by the statement: "The specimen before the section was obtained from the body of a child which I have positive evidence was delivered six years before her death by perfectly natural labour, head foremost." Mr. Brodhurst is fond of relying on single facts; he relies on such in his rejection of Guérin's theory. In his letter to THE LANCET he admits the value of this evidence, for he says: "It is said that one fact is worth a hatful of theory." If this be so, my case, complete in its history and pathology, confirmed by a well-attested series of preparations, is worth the whole hatful of his forty cases unverified by dissection. But Mr. Brodhurst would put my case and Hutton's alike out of the category of congenital dislocations, I suppose because their facts weigh heavily against his description of the deformity, and against his reasoning.

In reference to my recent dissection, he must needs twist my description of the pathological wasting of the fibres of the gluteal muscle into a proof that the muscle had been ruptured. He says that I "was struck with the destruction of the fibres of the gluteus maximus muscle; indeed, they had almost disappeared in places." He has overlooked the word "almost," and most curious is his deduction from this sentence. "Now, because there was no arrest of development, dislocation must have occurred through violence, and the violence must have been such as to rupture the fibres of the gluteus maximus." No one but Mr. Brodhurst could have extracted such a meaning from my words, and certainly but few could be guilty of a conclusion so illogical, even supposing his interpretation of the meaning of my words to be correct. Whoever heard of the fibres of the gluteus maximus being ruptured in a dorsal dislocation of the hip, congenital, pathological, or traumatic? And yet Mr. Brodhurst does me the favour to attribute such nonsense to me. "That has been left entirely for Dr. Bennett; and I doubt if anyone will contest the honour of the discovery with him." The discovery exists only in the fertile imagination of Mr. Brodhurst. I suppose he avoids the question of the position of the head of the femur as demonstrated by Hutton because it does not tally with his own published statements. He dismisses the case with a sneer, merely: "a hemiplegic idiot of thirty-one years." How comes it that every recorded dissection reveals facts identical with those seen in this specimen? Mr. Brodhurst ends with this wish: "I hope I may persuade Professor Bennett that my facts are worth more than his theory." If anyone will read the report of my address, he will find that I have avoided formulating any theory. I have merely said: "Although we might not arrive at the whole truth, it is better to know our ignorance than blindly to adopt a dogmatic assertion and say it is the truth."

If Mr. Brodhurst will honour me with a visit I shall show him my facts, and he may build any theory he pleases on them, so long as he does not put into my mouth statements so absurd as that the great gluteal muscle is ruptured in dorsal dislocation of the femur.

I am, Sir, your obedient servant,

Fitzwilliam-street, Dublin, Feb. 10th, 1885. EDW. H. BENNETT.

DOES COCAINE ACT UPON DEEP-SEATED PARTS?

To the Editor of THE LANCET.

SIR,—I note in a recent annotation the expression of an opinion that cocaine would not act upon deep-seated parts, and you mention the iris as an illustration of your meaning. As this is a question of great importance to all practitioners, especially to ophthalmic surgeons, I trust you will permit me to place on record some observations I have made on the subject. When solutions of atropine, eserine, or cocaine are applied to the surface of the conjunctiva, by a process of endosmosis they, to speak plainly, soak through the cornea and become diffused in the aqueous humour; they are thus brought into actual contact with the iris, and the extent of their influence upon that membrane depends entirely upon the strength of the solution, the frequency of the instillation, and the time that has been allowed to elapse from the date of the first application. I have frequently demonstrated this fact to students and medical practitioners by applying the aqueous humour—when it has been necessary to tap the chamber—of an eye thus treated to the fellow eye of the same patient, with the invariable result that the specific effect of the drug has been at once induced. On a recent occasion I applied the aqueous humour of a patient, who had been placed under the influence of cocaine in order to facilitate paracentesis of the chamber, to the eye of another patient from which I was about to extract a foreign body. Anæsthesia was induced, but we were surprised to find the pupil contracted, a circumstance that was only explained by referring to the first patient's prescription, when we found that he had been using a weak solution of eserine ordered elsewhere.

For years past I have been in the habit of operating upon a large proportion of my cases of senile cataract without any anæsthetic. First, because of the danger of chloroform, and secondly, because of the excitement, vomiting, and other inconveniences attending the administration of ether. Now, the critical part of the ordinary operation for cataract upon a conscious patient is the excision of a portion of iris after the preliminary incision has been made, and you are no longer able to control the eyeball or obviate the sometimes disastrous result of a sudden squeeze. I used to escape the peril attending this stage of the operation by accomplishing the incision of the cornea and excision of a portion of iris, *uno ictu*, with the knife as it crossed the anterior chamber, but since the discovery of cocaine I have been able to perform the iridectomy more deliberately with scissor forceps, and I may say, when the solution has been of sufficient strength and the application frequent, absolutely without pain. Take the following two cases as illustrative of the extraordinary results to be obtained from cocaine when applied in the manner described:—

J. S——, aged sixty-seven. This man was one of the most difficult patients to deal with I ever had to treat. He was a drinker, and used to get terribly excited in his "cups," and was so abnormally sensitive that it was impossible to touch his eye without an anæsthetic. Chloroform induced collapse, and ether had the same effect as alcohol. I became acquainted with these facts when extracting for cataract on the right eye six years ago, an operation which was completed without misadventure, but ended disastrously, because the patient tore off his bandage and squeezed out the contents of the globe in a fit of drunken excitement (induced by ether) after his removal from the operating

table. He was nearly blind in the left eye when the right was operated on, and gradually got worse, and for years was led about blind, obstinately refusing all treatment. After I had operated upon a few patients with cocaine, I sent for S—— and told him that I could remove his cataract without pain and without administering either ether or chloroform. After some demur he consented to submit, and I operated upon the 20th of last month. Iridectomy and all was completed without the slightest misadventure, the patient exclaiming, "I never felt you. I never felt you." "Why did you roll about, then?" I said. "I don't know," he replied; "but I never felt you."

The other case was that of a very delicate, nervous, and feeble woman, aged seventy-six, whose right eye had been lost by accident eight years ago, and the left had been blind from senile cataract for a year. Cocaine had been freely applied to the left eye with a view to extraction of cataract, and I requested the patient to lie down on the operating table. "You must chloroform me," she said. "It won't be necessary," I replied. "I shan't be done; I shan't be done if you don't give me the stuff," she said, getting excited. I had special reasons—into which I need not enter here—for withholding a general anæsthetic in this case, so I said, "Very well, you shall have your own way; lie down," at the same time applying an Ormsby mask without any anæsthetic to her face, directing her to breathe deeply. After a few minutes she said, "I get no forwarder." I said, "You will soon feel nothing," and directly afterwards applied the speculum. "I'm not gone!" she shouted. "Yes, you are," I said; "see, you don't feel," at the same time fixing the eyeball with forceps. She seemed literally struck dumb with amazement, made no further remark, and the cataract was extracted, iridectomy and all being performed without the slightest manifestation of pain. At the conclusion of the operation she said, "That is queer stuff. I thought one went to sleep." I replied, "I gave you only enough to send the eye to sleep, it was not necessary to do more." "Well," she said, as she was led away, "I felt no pain, that's certain."

Both these patients recovered excellent sight without subsequent pain or other bad symptom, and the former certainly could not have been operated on but for Dr. Köller's splendid discovery. I may add that I have now extracted in twenty-five cases of senile cataract, cases in which iridectomy has formed part of the operation, under the influence of cocaine, that in each case the operation has been completed without misadventure, and that all have made excellent recoveries.

I am, Sir, your obedient servant,

CHARLES BELL TAYLOR, M.D., F.R.C.S.E.,
Surgeon to the Nottingham and Midland Eye Infirmary.

February, 1885.

ANTISEPTIC SOLUTIONS OF COCAINE, ATROPINE, AND OTHER ALKALOIDS.

To the Editor of THE LANCET.

SIR,—It is quite evident that cocaine is destined to be used very extensively in all parts of the world, and therefore some attention should be given to the best means of preserving the activity of its solution. Already, too, it has been pointed out (*Dental Cosmos*, December, 1884) that after the lapse of only two weeks a fungous growth appeared in a solution, which is thought to have destroyed its efficacy. Such a result might of course be anticipated, knowing as we do how quickly such growths appear in vegetable solutions if in warm situations or exposed to the atmosphere.

More than six years ago I wished to discover what would prevent such changes taking place in atropine solutions, and I got Messrs. Corbyn and Co. to prepare for me a number of specimens of liq. atrop. sulph., P.B., each containing some antiseptic substance—amongst others thymol, camphor, salicylic acid, carbolic acid, chloroform, &c.,—the ultimate result being that I found, after allowing them to stand some months, that the preparations containing camphor or thymol still remained clear, whilst fungus had started to grow in the others. Camphor being as a rule more frequently at hand, and being otherwise convenient and suitable, I decided to employ it. I have therefore, during the last five years, in my prescriptions always directed that atropine or eserine be dissolved in camphor water. Upon considering the subject again in reference to the preservation of cocaine, I referred to those of my specimens which still exist, and I found that the one which had undergone the least apparent change is that containing thymol (half a grain to one ounce). It is still quite clear, colourless, and to the naked eye free from growth. On testing, however, its physiological effects, I find it produces no dilatation of the pupil, even after several instillations; whereas the camphorated solution (two grains of camphor to one ounce of liq. atrop. sulph.), which was made at the same time (1878), although a little turbid, is free from mycelium, and acts almost, if not quite, as quickly as if recently prepared. Having repeated the experiments with these solutions several times, and always with the same results, I conclude that, although camphor does not, in small quantities, prevent the advent of organisms in atropine solutions for an indefinite period, yet it preserves them free for one or two years, and at the same time it does not interfere with the mydriatic properties of the alkaloid. This fact will be appreciated by both surgeons and chemists; and, as it is probable that camphor will act in the same manner with solutions of other alkaloids, I would suggest that, until we have more definite knowledge, camphor in powder or as spirit of camphor be added to the solutions of cocaine. My experiments with eserine were commenced two years ago, but are not yet completed; but I may state here that, though camphor does not prevent the change of colour which nearly always takes place in its aqueous solutions, yet it is a good preservative; and that, when thymol is added, the eserine soon becomes inert. At some future time I hope to publish some observations on the preservation of both eserine and cocaine solutions, but some months must elapse before those in reference to the local anæsthetic can be of any value.

In 1881 M. Krœmer[1] pointed out that during the time he had used carbolised solutions (1 in 1000) atropine conjunctivitis, which previously had been of frequent occurrence, had not been seen in the clinic at Basle, and my own experience during the five years I have used atropine with camphor fully corroborates his statement. The solution made for me in 1878, however, with one part of carbolic acid in 500 did not long keep free from aspergillus, and I have no doubt carbolic acid is inferior to either camphor or thymol for this purpose. Judging from what I have seen, the conjunctivitis in these cases is not due to the "drops" containing too much acid, as I have failed to produce it with guttæ atropiæ to which three or four drops of dilute sulphuric acid had been added, or to any impurity of the drug, as cases occur where the irritation follows the use of a few only of the solutions prepared from the same stock and distributed widely. Nor is it due, I consider, to the visible forms of vegetable organisms, but rather to bacilli or micrococci which gain admission to some of them, and readily develop owing to the absence of any germicide, and it is therefore easy to surmise how camphor or carbolic acid is useful and necessary. Any collyrium containing camphor causes no extra pain or unpleasant sensation when applied to the conjunctiva, and as fungi after a time grow freely even in alum, borax, or zinc solutions, camphor or thymol may with advantage be added to these. In consequence of the absence of such a preparation of atropine in our Pharmacopœia, some years ago, when I prescribed gutt. atrop. sulph. with direction for it to be made with atropine and distilled water, I found subsequently on several occasions that the chemist had given liq. atrop. P.B., which, containing as it did some spirits of wine, produced considerable smarting, much to my own and the patient's annoyance. Besides the advantage to surgeons in having a solution of atropine always active and ready for use in ophthalmic cases, I might point out that even the atropine drops dispensed at hospitals, and therefore possibly made every few days, should contain some preservative.

Since writing the above I have read Mr. Fenwick's remarks in this week's LANCET, and I think he will find that ultimately the fungus will appear even in his 20 per cent. solution of cocaine, and that it is only delayed by the larger proportion of acid which the stronger solution contains.

I am, Sir, yours truly,

Tunbridge Wells, Jan. 31st, 1885. GEORGE ABBOTT.

COCAINE IN CHRONIC CYSTITIS AND IRRITABLE BLADDER.

To the Editor of THE LANCET.

SIR,—Any suggestion on the application of the new local anæsthetic is of value. After some experience of its efficacy in rectal and urethral operations, I was induced to try it in

[1] Corr—Blatt f. Schweiz Aerzte, xi.

those troublesome and often seemingly intractable cases of irritable bladder with spasmodic contraction of the sphincter vesicæ. The surgeon is often led to think that he is dealing with an absolute stricture, so sensitive and contracted is this portion of the canal that it hardly yields under an anæsthetic. I had made some small bougies of gelatine about three inches long, charged with one quarter of a grain of hydrochlorate of cocaine, of about the calibre of the normal urethra. These were pushed down the urethra to the irritable neck of the bladder by an ordinary elastic catheter, the result being that the patient in the first instance almost immediately expressed the opinion that he is "going to get control" over his bladder; and, secondly, that the surgeon was enabled at once to make a most thorough examination without his patient suffering any pain whatever. Of course the treatment must be continued; but in these most vexed cases, if the patient at the outset of fresh treatment experiences any relief, even for a limited time, he is on the high road to further improvement, and no doubt eventually to a cure. I am, Sir, yours, &c.,

Wimpole-street, Feb., 1885. EDWARD BELLAMY.

DEATH DURING ANÆSTHESIA.

To the Editor of THE LANCET.

SIR,—In your issues of Nov. 15th, 1884, and Jan. 24th of the current year two deaths during anæsthesia are recorded, the anæsthetics employed being methylene and ether respectively. In these cases a point of so much practical importance is raised that I venture to draw attention to it. A dangerous and misleading view, which the anæsthetist is apt to fall in with, is that which assumes that the danger to the patient and the degree of narcosis rise and fall *pari passu;* that the smaller the margin of vitality the less ether &c. should be given. I have often seen operations performed upon "unfavourable" cases, when the patient never became fully under, but came round time after time, the anæsthetist fearing to produce complete narcosis. But the truth is that the two "dangerous" points are the "half-under" and the "half-round" degrees of narcosis; but especially the former of these—when, that is, the energy of the respiratory and cardiac centres is lowered, whilst reflex susceptibility is not yet abolished, but rather intensified, a condition analogous to the irritability of exhaustion, when the breathing is irregular and the pulse rapid and feeble. To this succeeds, after a few inhalations, the quiet regular breathing, and fuller, slower pulse of complete narcosis. In the former condition (of semi-narcosis) any operative measure takes the patient at the greatest disadvantage. The deaths that I have seen, and some that I have read of, seem to me to have indisputably occurred during semi-narcosis, and to have followed with marked suddenness upon some operative proceeding. I have seen two deaths occur at the commencement of colotomy (a child and an old woman being the patients), both such feeble subjects that narcosis was not fully established. At the first skin incision the child's pulse ceased suddenly, almost as though it had been shot through the heart. The woman's case was strikingly similar; she had partially come round during a momentary delay in commencing, and was sick. As the first incision was made in the skin the woman gave a couple of gasps, and the pulse and breathing ceased together. In the case you record of death under methylene, narcosis was "with difficulty induced"; "the pulse was good," but "at the commencement of the operation the patient became rapidly cyanosed, and the heart's action suddenly ceased." What was the cause of death? Not some peculiar susceptibility of the system, for the patient had taken methylene on a previous occasion without difficulty; not his general condition of health, nor special cardiac condition, for both were good; evidently not the operation (division of the ulnar nerve). I think one must conclude that death was due to a fatal inhibitory impulse, excited by the incision, acting upon the heart during semi-narcosis. In the death during ether, the man "had partially come round," and the bag was put over his face without any more ether, whilst reduction of the dislocation was effected; in a minute or so he was observed to have become very pale, and the breathing very feeble; all attempts to revive him failed. Here, apparently, the shock of forcible reduction during semi-narcosis, acting upon a condition of great vital debility, was the cause of death. Apologising for occupying so much of your valuable space,

I am, Sir, yours, &c.,

Feb. 9th, 1885. J. PHILIP GLOVER, M.B.

RALPH WALDO EMERSON.

To the Editor of THE LANCET.

SIR,—It may interest some of your readers to know that Ralph Waldo Emerson (whose biography Dr. Oliver Wendell Holmes has just written) suffered during the last ten years of his life from well-marked symptoms of aphasia. According to Mr. Conway, "There was something striking in the kind of forgetfulness by which he suffered. He remembered the realities and uses of things when he could not recall their names. He would describe what he wanted or thought of. When he could not recall a 'chair,' he could speak of that which supports the human frame; and 'the implement that cultivates the soil' must do for a 'plough.'" This account of the ailment of the great American essayist is interesting from a medical standpoint, showing, as it plainly does, how an active brain will overcome apparently insurmountable physical difficulties due to localised disease of its substance. In the present instance I take it that this result was effected by utilising circuitous efferent nerve tracts in the healthy tissue around the lesion.

I am, Sir, yours truly,

Brighton, Feb. 5th, 1885. W. AINSLIE HOLLIS.

MANCHESTER.

(*From our own Correspondent.*)

THE MANCHESTER MEDICAL SOCIETY.

THIS Society has now completed its fiftieth year of existence, and at the meeting held on the 4th inst., Dr. Walter Whitehead took the chair as President for the ensuing year, in succession to Dr. Leech, who retires after having held that office for two successive years. Both financially and numerically it is in a very flourishing condition; it numbers 240 members, possesses the largest medical library in the provinces, and has had £500 bequeathed to it during the past year. It has lost two of its oldest members, Dr. Noble and Dr. Joseph Stone.

THE ROYAL INFIRMARY AND THE CORPORATION.

The dispute already noticed as having arisen between the Royal Infirmary and the Corporation, concerning the excessive charges of the former for cases of fever treated at their hospital, has resulted in the former paying in full the charges in dispute; and at the last meeting of the Infirmary Board certain proposals were brought forward and approved for submitting to the Health Committee of the Corporation: they are, briefly, that the Fever Hospital must be extended if the Corporation desire to continue the use of it; that the cost of such extension will be £20,000, of which sum the infirmary will provide about £3000, being the profit they have made by the treatment of the Corporation patients during the past three years, and that they will advance the remainder of the money as a loan to the Corporation, the latter to pay interest on such loan; that the infirmary will contribute £500 a year towards the maintenance of the hospital, the remainder to be found by the Corporation; and that the management of the hospital shall be retained by the authorities of the infirmary. These proposals have been submitted to the Health Committee, and their decision is now awaited before any further steps are taken.

SANITARY MATTERS.

At the last meeting of the City Council several matters of much sanitary interest came up for consideration. The Rivers Committee submitted a report upon their inquiries and investigation as to the best means of the disposal of sewage, with a view to the non-pollution of the river by sewage matters. The three systems of irrigation, intermittent filtration, and precipitation were described and their respective merits pointed out. The same committee are to make further inquiries and report again prior to the whole matter being gone into. Manchester has at present in operation over a very large area the pan system of closets with weekly removal, so that the problem here should present less difficulties than in towns where all sewage is turned into the sewers. The Parks Committee submitted a proposal for the purchase of a large open space in one of the suburbs, known as the Ardwick Polygon, and the Council sanctioned an expenditure of £20,000

for the purpose, some £9000 being promised as gifts towards the same object. A resolution also was passed that immediate steps be taken to remedy insanitary and dilapidated dwellings, especially with a view to the demolition of crowded and narrow passages, blind streets, and culs-de-sac, and the providing of open spaces in crowded districts; and these matters have led to some amount of correspondence in the daily newspapers, urging that this latter work is much more pressing than the providing an additional large space in Ardwick, which already possesses a small park or green, and that the £20,000 should be devoted to this purpose rather than the former.

SCHOOL HYGIENE.

The arrangements for holding a conference on Education under Healthy Conditions are progressing. The date fixed is April 14th and following days. At the last meeting of the Executive Committee, Lord Aberdare (who has consented to be President) was present, and the programme fixed upon included over-pressure, cheap dinners for poor school children, science teaching in schools, gymnastics and physical exercises, health lessons in schools, health requirements in the construction and fitting of schools, and evening schools.

ILLNESS OF PROFESSOR WATSON.

A profound feeling of grief was produced by the sudden and serious illness of Professor Watson on the 4th inst., the Dean of the Medical School. He was lecturing as usual on that day, and at the conclusion of his lecture was seized with an apoplectic attack. He was unable to be removed home, and has had to remain at the College, where he still lies in a very critical condition.

LIVERPOOL.

(From our own Correspondent.)

THE LIVERPOOL GYMNASIUM.

AMONG its other public institutions Liverpool possesses one of the finest gymnasia, if not the finest, in the kingdom, and seeing how greatly it contributes to the physical well-being of its members it may be considered partly a medical institution. For years its financial position has been unsatisfactory, but within the last few days it has been freed from debt, and there is every reason to hope that it has a long and prosperous career before it. It is most interesting to observe the effects of the various dumb-bell, bar-bell, and Indian club exercises upon boys and youths with narrow chests and ill-developed muscles, the difference being in the course of twelve months most remarkable. In this large city, where so many young men have to spend the best part of the day in offices and shops, often in a stooping posture, the gymnasium affords an excellent mode of correcting in the evening the ill effects of the work of the day. Many ladies also have derived considerable benefit from attending the class provided for them on certain days at special hours, and in many cases, other than those specified, there could not be a better prescription than twelve months at the gymnasium.

THE ROYAL SOUTHERN HOSPITAL.

In 1841 the south end of the town had extended so much that hospital accommodation was required, and the old Southern Hospital was built and opened. Being found quite inadequate for the demands made upon it, the present hospital was erected about twelve years ago with all the modern improvements of hospital construction. The annual meeting was held on the 9th inst., when it was reported that the total number of patients treated during the past year was 893, and the daily average number of beds occupied was 165; the wards were frequently quite full. In the annual report a graceful allusion was made to the late Mr. Alfred Higginson, who had been connected with the hospital since 1857, for ten years as honorary surgeon, and since then as honorary consulting surgeon.

THE SEAMEN'S DISPENSARY.

At the annual meeting of the Sailor's Home, Dr. Bernard, surgeon, reported that during the year there had been 801 new cases treated at the Seamen's Dispensary, and that the total number of visits made by patients during the year was 2401.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

NEWCASTLE INFIRMARY.

THE annual meeting of the Newcastle Infirmary was held last week, and the proceedings were full of interest. I need not refer again to the subject of overcrowding and the proposed new building, as this has been already dealt with in this correspondence. The statistics of the past year, as the report says, "show an amount of effort on the part of the professional officers of the house which is truly gratifying, and indicate an amount of relief given to human suffering which must afford much satisfaction to the supporters of this noble institution." The total number of patients treated in the infirmary during the year has been 31,714. The number of in-patients has been 2576, being an increase over that of the previous year of 490. Of the ten patients operated on for stone in the bladder all recovered. Twenty-nine cases of fracture of the skull had been treated, with eighteen recoveries; and fifteen cases of concussion of the brain, with only one death. Ovariotomy has been performed eleven times, with three deaths. The report also refers to compound fracture of the leg, which was so frequently fatal before the adoption of the antiseptic methods, but seventeen of these fractures had been treated, with only one death. With regard to the introduction of working men to the committee, now under consideration, one result would, it is thought, follow this arrangement—namely, an increase in the contributions made by the working classes to the funds; for at Sunderland, where the average number of patients is less than one-half of the number received by the Newcastle Infirmary, but where representatives of the working classes hold office, the workmen's contributions continue to form the most important item in the income of the institution. At this meeting a proposition was brought forward that a small charge be made for every casual case seeking medical aid at the infirmary. It was pointed out by the house-surgeon, Dr. Limont, that the casuals included all classes of patients, from tramps and persons in the lowest position, to persons who were well dressed and well able to pay. Dr. Philipson stated that the Medical Board were opposed to the making of a charge; he thought it would not deter many of the better classes seeking assistance, while the sick and suffering poor might often be prevented from doing so. This opinion of the Medical Board appeared fatal to the project, for it was dropped.

NEWCASTLE DISPENSARY.

This old-established and valuable institution had its one hundred and seventh annual meeting last week. The committee's report stated that there had been a decrease of 957 letter patients during the year as against the previous year, and a decrease of 2176 in the number of casual patients, but the number of patients treated during the year reached the large total of 18,717. The tables compiled by Dr. Beatley, the resident medical officer, show that the percentage of deaths was much lower than in 1883, in the proportion of 2·8 against 3·1. Dr. Beatley's tables show also that there has been a gradual falling off in the number of casuals yearly since 1882. The casuals pay a small sum before being admitted to treatment, but as the Newcastle Infirmary, and other charitable institutions in the city, see patients free when work is bad, a large number will naturally gravitate to them. It should be explained that at one time the pressure of casuals became so great that it promised to take up the whole time of the staff, and the charge was put on as a check, and as such it has proved itself to be an effectual one. It might, however, become a question for the committee as to whether at a time like the present it might not be expedient, or even humane, to remove the small payment, for which the institution has no pressing need, seeing that it has an invested capital of about £30,000, and a well maintained list of subscribers.

DEATH OF DR. ADRIAN BLAIKIE.

Our papers notice with regret the death of Dr. Adrian Blaikie, Her Majesty's Inspector of Alkali Works for this district. Dr. Blaikie, although not a member of our profession, was intimately connected with it by his education and duties. He was a son of the Rev. Dr. Blaikie of Edinburgh, and was well known in the University by some important

investigations he conducted there with Professor Crum Brown. He was a Doctor of Science and Fellow of the Chemical Society of London. His loss will be severely felt by many personal friends he made here since his appointment last session; he was only twenty-eight years of age.

Newcastle-on-Tyne, Feb. 11th.

PARIS.

(From our Paris Correspondent.)

DEATH OF DR. MALLEZ.

IT is with much regret I have to report the death of Dr. Mallez, which took place at his residence in Paris, in the fifty-eighth year of his age. The deceased gentleman had an attack of apoplexy on Friday, the 30th ult. (this being the third attack within a few months), which resulted in paralysis, and he remained unconscious to the day of his death, on Wednesday, the 4th inst. After having completed his classical studies he entered the army as an assistant-surgeon, which he left in 1851, and in 1858 he took his degree as doctor of medicine, the subject of his thesis having been on "Hæmatocele of the Vestibule of the Ear in Wrestlers, Lunatics, and School Children." Nothing, however, indicated his inclination towards the specialty he afterwards adopted—viz., diseases of the urinary organs, a branch in which he excelled, being considered one of the most competent authorities on the subject. The first indication that he gave of his aptitude for the practice of this particular branch was a work he published many years ago on the value of the introduction of powdered bismuth into the urethra in gonorrhœa, when he at the same time founded a dispensary for gratuitous consultations at his own expense, which was well attended by patients, medical students, and even by qualified practitioners from all parts of the world. His private practice was a very lucrative one, and he has left behind him a very large fortune. He was never married. Notwithstanding his busy practice, he found time to write, and among the works published by him was a memoir on the permanent cure of strictures of the urethra with the chemical galvano-caustic, for which he was awarded a prize by the Paris Academy of Medicine in 1867. In 1872 he brought out a work on the diseases of the urinary apparatus, and in 1883 his formula of diseases of the urinary organs appeared. Dr. Mallez was a very able practitioner, and was much sought after in society, as he was in every sense an artist in physique, in taste, and in manners. He was a Chevalier of the Legion of Honour. His funeral took place in the midst of a large concourse of friends and grateful patients in the church of St. Roch, which, although a building of the first class in size, could scarcely hold the numbers who flocked thither to pay their last respects to the memory of the deceased. After the funeral service the body was removed to Valenciennes, his native town, for interment.

Paris, Feb. 10th.

MAHOMED MEMORIAL FUND.

THE following additional subscriptions have been received:

	£	s.	d.
W. A. Crosse, Esq.	1	1	0
E. G. Dutton, Esq.	1	1	0
A. Withers Green, Esq. ...	1	1	0
R. L. Knaggs, Esq., M.B.	1	1	0
T. B. Luscombe, Esq. ...	1	1	0
H. Kellock McKay, Esq., 32nd Pioneers...	2	2	0
Laidlaw Purves, Esq. ...	10	10	0
John Rand, Esq.	1	1	0
Mrs. Henry Roberts, per Dr. Arcedeckne Duncan	1	1	0
Dr. Swain Scriven	1	1	0
C. Caldecott, Esq.	1	1	0

A meeting of the Committee will be held very shortly, and the treasurer or honorary secretaries will be glad to receive the names of any gentlemen still intending to contribute to the fund.

ARTHUR E. DURHAM, Treasurer.
JAMES F. GOODHART, } Secretaries.
W. H. A. JACOBSON, }

SANITARY ASSURANCE ASSOCIATION.—The fourth annual meeting of the members of this Association was held on the 9th inst., when the annual report and financial statement for 1884 was read. The report, which was adopted, was a most satisfactory one, and pleasure was expressed at the steady progress which had been made during the past twelve months.

Obituary.

COSTANZO MAZZONI.

A GREAT surgeon, a great teacher, and an exemplary citizen has been lost to Italy in Costanzo Mazzoni, who died in Rome, almost at his patient's bedside, on Thursday, the 5th inst. It was no secret that he had for a long time been labouring under organic cardiac disease; but his devotion to his profession was such that no admonition of impaired power could ever make him decline or postpone any summons to the ailing. On the morning of his death he had gone with an assistant to attend a patient in the Palazzo Fiano, and in mounting the stairs felt ill; his companion advised him to rest a little, but he insisted on going on till he entered his patient's house. In a moment he was seized with the most agonising præcordial pain, and then the heart's action stopped. He was no more.

He was born at Ascoli-Piceno in the Marches in 1823, and came up with a solid classical training to Rome, where he highly distinguished himself as a student of medicine. He finally concentrated all his energies on surgery, in which he graduated; then started on a tour through the chief European medical schools, and for some time made Paris his headquarters. On his return to Rome he worked assiduously with his learned teacher and friend, Antonio Baccelli, with whose still more distinguished son Guido he formed the fraternal relations which only ceased with his life. In private practice he soon rose to eminence, but never lost touch with contemporary science in its manifold developments. His chief recreations were his visits to the great European schools, and his attendance at the Congresses periodically held at them. On these occasions he never failed to contribute, as well as to carry away, valuable knowledge, and from the experience thus acquired he formed the conception which he lived to mature, but not to realise, of founding in Rome a model medical school, while converting his old hospitals into institutions for the treatment and study of special diseases. He was in frequent communication with the men of light and leading among his contemporaries, and numbered as his correspondents many surgeons of the first rank, from Lister to Billroth. It is hardly possible to over-estimate what clinical teaching in Italy owes to him. In Rome especially he continued to train from year to year an ever-increasing phalanx of young surgeons who flocked to his prelections and operations from all parts of the Peninsula. Not Acquapendente, not Scarpa insisted more impressively than he on the importance of anatomy as the basis of surgical proficiency, while on all his academic deliverances rested the mellow afterglow of scholarship, the chastened light and colouring of a mind imbued with the best spirit of the antique. Virgil and Horace he knew as a humanist of the Renaissance might have known them, and he took special pleasure in relieving from time to time the closeness of clinical work by a lecture on some of the great fathers of medicine, from Hippocrates to Galen, from Oribasius to Alexander of Tralles.

As Professor of Clinical Surgery in the Roman University he issued yearly reports of the chief cases of scientific and practical interest in the wards of the San Giacomo Hospital. These volumes are a rich mine of observation and suggestion, and form excellent reading not only for the student, but for the practitioner. In all of them an impression of thoroughness is conveyed—the characteristic of a mind not only well instructed but well educated. His papers read before the Accademia Medica di Roma are marked by the same features, and their speedy publication in an accessible form will be the pious duty of his colleagues and executors.

The funeral took place on Saturday, the 7th, and many incidents in the life of the deceased combined to make it a singularly impressive demonstration. He had served in the movement which led up to Italy's unity—had been surgeon, in fact, to the Garibaldian forces in the brilliant, if unsuccessful, expedition of Velletri in 1849, and so the survivors of the campaigns of independence were conspicuous among the mourners. He had found time, though at the

head of his profession in Rome and the surrounding provinces, to give gratuitous advice daily to the poor—his house in the Via Mario dei Fiori being on these occasions a kind of dispensary, often of other aid than medical only; and so the funeral cortège was swelled by many humble and grateful recipients of his bounty. Add to these his colleagues of the Senatus of the Roman University, the students of every faculty in that seat of learning, the leading physicians and surgeons of the city, representatives of the various Universities and of the learned and scientific bodies, not only in Rome, but throughout the Peninsula, and the Ministers of the Interior and of Public Instruction on the part of the Government, and some idea may be formed of the solemn procession which moved slowly through the Via Frattina, the Corso, the Via Condotti, the Piazza di Spagna, till it reached the Baths of Diocletian. There it paused before resuming its progress to the cemetery, and among the pall-bearers were Prof. Maurizi, Rector of the University; Prof. Galassi, President of the Faculties of Medicine and Surgery; Prof. Guido Baccelli, President of the Roman Academy of Medicine; Signor Mercatili, the parliamentary representative of Ascoli; the Senator Gravina; the Senator James Moleschott, Professor of Physiology in the University; and the delegates of the Town Council and the Government. Several delivered brief and touching orations over the surgeon, the savant, and the citizen lost to Rome and to Italy. Then the cortège dispersed, all but his immediate relatives and friends and his students, who accompanied his body to the Campo Verano, where it was laid to rest under wreaths of spring flowers.

On Sunday, the 8th inst., the ordinary meeting of the Roman Academy of Medicine suspended its programme, the President, Dr. Guido Baccelli, referring in a few well-chosen words to the loss it had sustained. The following resolutions were thereafter proposed and carried:—1st. To hold a conference in the grand hall of the University in honour of their lamented colleague's memory, inviting the attendance of the urban and provincial authorities, the leading citizens, the medical faculties of the kingdom, and the medical societies, Italian and foreign. 2nd. To place a marble bust of him in the University at the expense of the Academy of Medicine. 3rd. To withhold for one year the nomination of his successor in the membership of the Academy. A committee—composed of Drs. Galassi, Pasquali, Durante, Tassi, Francesco Scalzi, Filippo Scalzi, Brunelli, Bertini, Laurenzi, and Gaetano Mazzoni—was charged to co-operate in compiling a memoir of their late colleague as surgeon and teacher, man of letters and citizen.

As we write, Dr. Giordani, of the San Giacomo Hospital, the scene of his colleague's most brilliant operations, sends us the following note:—"Professor Mazzoni suffered of late years from difficulty of breathing, accompanied by painful spasms along the left arm. These symptoms were due to long-standing atheroma of the aorta and consequent hypertrophy, with fatty degeneration of the heart. The proximate cause of death was cardiac paralysis." The body was embalmed by Professors Durante and Postemski, assisted by Drs. Bonanno, Crespi, Braggio, and Tricomi. It is to be hoped that Professor Mazzoni's own method of embalming, of which he is understood to have preserved the secret, and the highly successful results of which brought him much distinction, will not be allowed to die with its author.

FRANCIS GRIERSON, M.B., C.M.

IT is with great regret that we record the death of one who, although but a young member of the profession, gave every promise of a distinguished career. He was one of the many victims of overwork. After five years of patient study at Edinburgh University, Mr. Grierson graduated with honours in August, 1883; and at that time he proposed to devote himself to mental diseases, for which his special aptitude for microscopical work and pathological research would have stood him in good stead. All his plans were, however, altered by the symptoms of incipient consolidation showing themselves, and in the hope of recruiting his overtaxed strength he took a voyage to Sydney. Shortly after his arrival a vacancy occurred among the residents in the Prince Alfred Hospital, for which his love of the profession induced him to compete at a time when he was physically unable. For nine months he manfully filled his post, and then resigned, being compelled to do so by the advancing nature of his complaint. He was on the eve of leaving for the more congenial Cape, when death overtook him on the 8th ult. In him are realised the words of the wise man, "For honourable age is not that which standeth in length of time, nor that is measured by number of years."

FREDERICK ANTHONY MILLS.

MR. MILLS, whose death in the eighty-fifth year of his age occurred on the 29th ult., was born at Pulham St. Mary, in Norfolk, where his father practised for many years. He received his early education at the Norfolk Grammar School under Valpy, and afterwards prosecuted his professional studies at Guy's Hospital. After a short period of study at the Paris School of Medicine, Mr. Mills commenced the practice of his profession in Norwich, where he was speedily successful. On his retirement he located himself first at Horning and afterwards at Surlingham, where he died. Two years before his death Mr. Mills had suffered from strangulated hernia, for the relief of which he underwent, without anæsthetisation, a severe operation, recovering perfectly. Then and since, however, he suffered from prostatic enlargement and cystitis, to which of late was added stone in the bladder, and, gradually exhausted by these accumulated troubles, he at last succumbed.

SURGEON G. S. LEWIS, M.A. CANTAB.

WE learn with regret the death of Surgeon G. S. Lewis, Medical Staff, which occurred on the 6th inst., at Davos Platz, after a lingering illness. Born in Tasmania in 1852, and educated at the High School, Hobart, Mr. G. S. Lewis left home never to return in 1868. He became attached as a medical student to Guy's Hospital, and subsequently to Gonville and Caius Colleges, Cambridge. During his few years of service he was stationed at Gosport, Aldershot, and Gibraltar, and finally at Ramleh. The energy with which he devoted himself to his onerous duties during the cholera epidemic in Egypt probably laid the foundation of the disease to which he succumbed. His kindness of heart, his generosity, and his genuine but unobtrusive cheerfulness will long be remembered by those who knew him best.

Medical News.

BRITISH MEDICAL SERVICE.—The following are the names of the successful surgeons on probation for Her Majesty's Army, in order of merit, and with the number of marks obtained by them. In the instances of these gentlemen the marks gained at Netley are not counted, and they retain the places taken by them in the competitive examination at London.

INDIAN MEDICAL SERVICE.—The following is the list of candidates for commissions as surgeons in Her Majesty's Indian Medical Service, in order of merit, and with the total number of marks gained by them at both the London and Netley examinations:—

	Comb. Marks.		Comb. Marks.
*Leslie, J. T. W. ...	5521	Mukerji, U. N.	4961
Prain, D.	5411	Price, W. L.	4798
Bown, A. T.	5285		

*Gained the Herbert Prize of £25 with the Martin Memorial Gold Medal, and the Montefiore Second Prize.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on the 5th inst.:—

Cattell, George Trew, Guy's Hospital.
Constable, Samuel, St. George's Hospital.
Fernandez, Lawrence J. Baptist Paul, Medical College, Calcutta.
Goulden, Henry William, Charing-cross Hospital.
Hunter, George Holbrey, University College.
Price, Arthur Edwin, Guy's Hospital.

The following gentlemen also on the same day passed the Primary Professional Examination:—

Walter Loades, Middlesex Hospital; John Eugene St. George Queely, Meath Hospital, Dublin; Alfred Hobart Sturdee, King's College.

AT the Sorbonne, where micro-biology has recently been raised to the rank of a recognised science, M. Duclos, one of the most distinguished of M. Pasteur's pupils, has been appointed the first Professor of Bacteriology.

THE total receipts since the inception of the Hospital Saturday movement in Melbourne have amounted to £73,195. By the last collection nearly £8000 was raised, an increase of about £800 over the receipts for the previous year.

THE Committee of the Ladies' Sanitary Association have arranged for the delivery of a course of lectures on "Physiology and the Laws of Health," to commence on the 26th inst., and to be continued every Thursday, with the exception of the Easter vacation, until twelve lectures have been given.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—The subscription list of this Hospital Saturday Collection has just closed. The amount realised for the year 1884 is £2191, being an increase of £41 over the year 1883, and of £30 over the year 1882. The expenses of collection have amounted to 2½ per cent.

FRENCH HOSPITAL AND DISPENSARY.—The seventeenth annual dinner in aid of the funds of this institution was held in Willis's Rooms on the 7th inst., M. Waddington, the French Ambassador, presiding. The report, which was read by the secretary, showed that during the past year the receipts had been £2616, and that the expenditure had amounted to £2300. A list of subscriptions and donations was afterwards read, showing that over £2000 had been received during the evening for the funds of the institution.

THE PARISIAN SEWERAGE SYSTEM.—The sewerage scheme for Paris devised by Dumont contemplates the construction of a drain about 100 miles long from the city to a covered reservoir below Herblay, and the establishment of pumping stations at Eragny and Serifontaine. The cost of construction is estimated at £2,400,000. For nine months in the year almost all the sewage will be utilised for the purposes of irrigation; and it is expected that the pumping stations will be fully maintained by the sales of the sewage.

A MORTUARY FOR PADDINGTON.—The Paddington vestry having recently decided to erect a public mortuary and coroner's court, a committee was appointed to select a plan. At the last meeting of the vestry, however, when the decision of the committee was brought up for approval, it was resolved that only a mortuary, and not a coroner's court, should be provided, one of the grounds assigned being that, as the Home Secretary had announced his intention to reintroduce his London Government Bill, it was undesirable to expend more than was necessary.

BEQUEST.—The late Dr. Bholanath Bose, formerly Civil Medical Officer of Faridpur, has left to the Calcutta Medical College all his scientific instruments and medals and a sum of 1000 rupees. The instruments are to be placed in the library for the use of students; the money is to be invested, and the interest is to be awarded annually to the fourth-year's student who shall show the greatest proficiency in the bedside diagnosis of disease, the prize being awarded for medical and surgical diagnosis in alternate years.

THE PARKES MUSEUM OF HYGIENE.—At the annual meeting of the members of the Parkes Museum in December last, the report of the Council gave indications of a financial crisis in the affairs of the museum, and the meeting unanimously resolved, on the motion of Mr. Mark H. Judge, "That the report be printed, with a detailed statement of the financial position of the museum, and sent to the members, and that a special meeting of the members be convened within two months to consider the same." This special meeting was held last week. Captain Galton, C.B., F.R.S., presided, and the meeting entered thoroughly into the work of doing the utmost to preserve the institution for the benefit of the public. To do this at least £1000 will be required by the end of February. A committee was appointed to assist the Council in obtaining the necessary funds to enable the museum to purchase the lease of the present premises in Margaret-street, and to make the necessary improvements to accommodate the great increase in the library, owing to the presentation of 1500 volumes just made by the Council of the International Health Exhibition. The joint committee of members and Council have arranged to hold a public meeting at the Mansion House to-day (Friday, Feb. 13th), at three o'clock.

CAMBRIDGE UNIVERSITY.—At a congregation on the 5th inst., the following were, on the recommendation of the General Board of Studies, appointed electors to the undermentioned Professorships until February 20th, 1893:—Chemistry: Mr. G. F. Cobb. Anatomy: Professor Newton. Botany: Dr. Phear. Zoology and Comparative Anatomy: Mr. F. Darwin. Surgery: Dr. D. Macalister. Downing Professorship of Medicine: Professor Liveing. Pathology: Professor Humphry.—The degree of Bachelor of Medicine was conferred on John Yates Bostock, Pembroke.

OVER-PRESSURE IN BOARD SCHOOLS.—A large number of answers have been received by the General Association of Church School Managers and Teachers, in response to certain inquiries on this subject issued by them to their various branches throughout the country. All, with the exception of two, state that over-pressure exists, and manifests itself in the ill-health of the children. The remedies suggested are an increase of the fixed grant, a relaxation of the excessive requirements of the Code, and a greater liberty in the matter of withdrawing delicate and backward children from examination. A letter embodying the above proposals has been sent to Mr. Mundella.

MANCHESTER ROYAL EYE HOSPITAL.—The total number of patients registered on the books of this institution during 1884 was 15,427, an increase of 725 on the year preceding. About £5000 is still needed to make up the amount the Board of Management asked for last year for the building and furnishing a new hospital, and a circular has been issued to the residents in the neighbouring towns, which furnish about three-fourths of the in-door patients, the maintenance of whom makes the largest item in the expenditure of the institution, calling their attention to the inadequate aid they give in proportion to the benefits they receive from the charity.

VENTNOR CONSUMPTION HOSPITAL.—At the annual meeting of the governors of this institution held this week, it was stated that the hospital, which consists of sixteen houses, has been fully occupied during the past year, and that there were constantly fifty or sixty applicants waiting their turns for admission. Three more houses have been erected during the past year, and will shortly be occupied. The ordinary receipts amounted to £9295, and the expenditure to £9816. The Earl of Rosebery has been chosen President, in succession to his late Royal Highness the Duke of Albany. The meeting was afterwards made special for the purpose of receiving the grant of a Royal Charter of Incorporation, which was submitted and approved.

MANCHESTER MEDICO-ETHICAL ASSOCIATION.—The annual meeting of this Association was held on Jan. 30th. The report of the committee showed continued prosperity, with a steady increase of members and funds. The retiring president, Dr. Lloyd Roberts, gave a very able and interesting address, after which the following gentlemen were elected office-bearers and members of committee for the year 1885:—President: F. H. Walmsley, Esq. Vice-Presidents: G. Bowring, Esq.; C. H. Braddon, M.D.; C. J. Cullingworth, M.D.; S. Woodcock, M.D. Treasurer: D. Lloyd Roberts, M.D., F.R.S.Edin. Secretaries: J. Broadbent, Esq.; A. Wahltuch, M.D. Committee: W. Armstrong, Esq.; W. H. Barlow, M.D.; F. H. Collins, M.D.; A. Emrys-Jones, M.D.; J. Foster, Esq.; W. J. Mallett, M.D.; S. H. Owen, M.D.; J. A. Palanque, Esq.; F. M. Pierce, M.D.; S. Rains, Esq.; A. E. Sutcliffe, Esq.; W. Walter, M.D.

NEW UNIVERSITY MEDICAL SCHOOL AT SYDNEY.—With the assistance of the New South Wales Government, a Medical School is to be established in connexion with Sydney University, and plans for a suitable building, in the Gothic style, have been prepared by the colonial architect. The length will be over 200 ft., with a depth of 115 ft., and walls 60 ft. high. In the main portion of the ground-floor are rooms for lecturers on pathology and medicine, an anatomical museum, medical class museum, and pathological, histological, and private physiological laboratories. The right wing is set apart as a class-room for practical pathology, with smaller rooms for a materia medica museum, laboratory, and lecturer's room. In the left wing are provided rooms for chemical physiology, physiological class museum, instrument and balance room, experimental physiology, physiological workshop, and a large room for the practical histological class. The dissecting-room is situate on the upper floor. A large theatre of anatomy, also one of surgery, and museum, each measuring 36 × 44 ft., surgical class-room, surgical lecturer's room, midwifery class museum, midwifery lecturer's room, anatomy professor's room, anatomical laboratory, demonstrator of anatomy room, small theatre of anatomy, and prosectory, occupy the main portion of this floor. In the right wing there is a theatre of pathology and materia medica, and one of midwifery and medical jurisprudence, each 36 × 45 ft. in measurement. The dissecting-room and theatre of physiology, measuring 51 × 41 ft. each, are in the other wing. The basement-floor is set aside for quarters, students' reading-room, coffee-room, injecting-room, medical jurisprudence lecturer's room, experimental physiology and pathology; large minto-tiled corridors, 10 ft. wide, running the whole length of the building. The estimated cost is £20,000.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

AITKEN, JOHN S., L.F.P.S.Glas., L.R.C.P.Ed., has been appointed Medical Officer for the Orton District of the East Ward Union, vice Durand, deceased.

BAILEY, W. H., M.R.C.S., L.S.A.Lond., has been appointed a Resident Clinical Assistant to the City of London Hospital for Diseases of the Chest, Victoria-park.

BATMGARTNER, JOHN RICHARD, M.R.C.S., L.S.A.Lond., A.K.C., has been appointed Police Surgeon to the City and County of Newcastle-upon-Tyne, vice Septimus W. Rayne, F.R.C.S.Eng., resigned.

BENNET, B. G., M.B., C.M.Ed., has been appointed Medical Officer of Health for the Fettercairn District, vice Walker, resigned.

BENTLIF, P. B., M.R.C.S., L.S.A.Lond., has been appointed Surgeon to the s.s. *Australia*, taking troops to the Soudan.

CARTER, EUSTACE G., M.R.C.S. & L.R.C.P., has been appointed House-Physician to the Bradford Infirmary, vice H. W. Phillips, M.B. resigned.

CASSEL, CHARLES E., F.I.C., F.C.S., has been appointed Public Analyst for the Parish of Kensington.

COLLIER, WILLIAM, M.A., M.B.Cantab., has been appointed Honorary Physician to the Radcliffe Infirmary, Oxford.

EVANS, OWEN, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Llanrwst District and Workhouse, Llanrwst Union, vice Hughes, deceased.

GALLIMORE, THOMAS AUSTIN, L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer for the Lymm District of the Altrincham Union, vice Brabazon.

GELSTON, J. S., L.R.C.S.I., L.K.Q.C.P.I., has been appointed House-Surgeon to the Doncaster Infirmary, vice J. G. Marshall, M.B.Cantab., M.R.C.S., resigned.

HARLE, WILLIAM J. V., M.R.C.S., L.S.A.Lond., has been appointed Resident Dispensary Surgeon to the Bradford Infirmary, vice Carter, promoted.

JEFFERIES, HORACE, M.R.C.S. & L.S.A.Lond., has been appointed House-Surgeon to the Bridgnorth Infirmary and Dispensary, vice R. D. Kirby, M.B., resigned.

MORGAN, GEORGE, L.R.C.P.Lond., M.R.C.S., has been appointed House-Surgeon to the Royal Alexandra Hospital for Sick Children, Brighton, vice Ryding Marsh, M.B.Lond., resigned.

MOSLEY, REGINALD LAWSON, M.B.Dub., L.R.C.S.I., has been appointed Medical Officer for the North Elmham District of the Mitford and Launditch Union.

NEILL, JOHN, L.K.Q.C.P.I., L.R.C.S.I., has been appointed Resident Surgeon at Steevens's Hospital, Dublin, vice Myles.

NORMAN, CONOLLY, M.K.Q.C.P.I., F.R.C.S.I., has been appointed Resident Medical Superintendent at Monaghan County Lunatic Asylum.

PASTEUR, WILLIAM, M.D.Lond., M.R.C.P.Lond., has been appointed Medical Registrar to the Middlesex Hospital, vice J. J. Pringle, M.D., M.R.C.P., resigned.

PHILLIPS, HENRY W., M.B., C.M.Ed., & M.R.C.S., has been appointed Senior House-Surgeon to the Bolton Infirmary, vice T. G. Stonham, M.D.Lond., resigned.

PINCOTT, ROBERT, M.R.C.S., has been appointed Health Officer for the Port of Geelong, Victoria, vice Mackin, deceased.

ROBERTSON, GEO. J., M.B., C.M., has been appointed Honorary Surgeon to the Oldham Infirmary, vice Dr. McGowan, resigned.

SMITH, HENRY, M.B.Lond., S.Sc.Cert.Camb., F.C.S., has been appointed Public Analyst for Woolwich. Also for the Plumstead District.

STACEY, W. H. WATERHOUSE, L.R.C.P.Ed., M.R.C.S., has been appointed Medical Officer for the Eastern District and Workhouse of the Freebridge Lynn Union, vice Alexander.

WESTLAKE, ALGERNON, M.B., C.M.Ed., has been appointed House-Surgeon and Secretary to the Hertford General Infirmary, vice Oakley.

WHEATLY, A. W., M.B., S.Sc.C.Dur., M.R.C.S., L.S.A.Lond., has been appointed Assistant-Surgeon to the Western Ophthalmic Hospital, vice T. W. Carmalt Jones, F.R.C.S.Ed., promoted.

WILLIAMSON, ALBERT VAUGHAN, L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer for the Howden District of the Auckland Union.

Births, Marriages, and Deaths.

BIRTHS.

COOKE.—On the 30th ult., at Warrior-square, St. Leonard's-on-Sea, the wife of John Cooke, M.B.Lond., of a son.

DAVIES.—On the 3rd inst., at Abercarn Fach, near Newport, Mon., the wife of Francis Joseph Davies, F.R.C.S., of a son.

DIMMOCK.—On the 3rd inst., at Shikarpur, Sind, India, the wife of H. P. Dimmock, Indian Medical Service, of a son.

KIDD.—On the 4th inst., at Brook-street, Grosvenor-square, the wife of Percy Kidd, M.D., of a son.

LAMMIMAN.—On the 8th inst., at Elleray, Tunbridge Wells, the wife of Cleland Lammiman, F.R.C.S.Eng., of a daughter.

MACQUEEN,—On the 7th inst., at Clarendon-crescent, Edinburgh, the wife of Daniel Macqueen, Deputy Surgeon-General, Army Medical Department, of a daughter.

STRUGNELL.—On the 10th inst., at Highgate-road, the wife of F. W. Strugnell, L.R.C.P., M.R.C.S., of a son.

MARRIAGES.

FORBES—YOUNG.—On the 4th inst., at Hailes Cottage, Kingsknowe, by the Rev. James Morrison, Free Church, Corstorphine, and by the Rev. W. R. Gray, D.D., Liberton, Alexander Forbes, M.B., C.M.Ed., Northfield, Liberton, third son of Alexander Forbes, H.M.'s General Register House, to Maggie Fortune, daughter of John Young, merchant, Edinburgh.

PILKINGTON-LOW—HUTCHINSON.—On the 11th inst., at St. George's, Hanover-square, by the Rev. W. Smale, Vicar of St. Philip's, Kensington, Richard Marsden Pilkington-Low, M.B., to Marianne Neville, widow of J. D. Hutchinson, late M.P. for Halifax.

SALTER—BROWN.—On the 9th inst., at St. Martin's Church, Salisbury, George Herbert Salter, L.R.C.P., M.R.C.S.Eng., of Malmesbury, to Edith Mary, second daughter of Jas. Brown, Southview, Salisbury.

SMYTH—DOBSON.—On the 4th inst., at the Parish Church of Little Saling, Essex, Wm. D. Smyth, M.D., Staff Surgeon R.N., to Cecilia, daughter of the Rev. R. S. Dobson, Vicar of Little Saling.

UPPLEBY—LYLE.—On the 10th inst., at the Mayfield-road Wesleyan Chapel, Dalston, by the Rev. G. C. Mayes, brother-in-law of the bride, assisted by the Rev. J. H. Morgan, John George Uppleby, L.R.C.P. and M.R.C.S.Ed., only son of Geo. Uppleby, of Port Elizabeth, to Edith Elizabeth, youngest daughter of the late Dr. Lyle, of Ashburton, Devonshire.

DEATHS.

DAVIDSON.—On the 3rd inst., at Sandown, Isle of Wight, W. A. Davidson, M.D., formerly Surgeon 65th Regiment, aged 54.

NIVISON.—On the 10th inst., at 161, Ledbury-road, Bayswater, London, W., Thomas Renny Strachan Nivison, M.D., aged 42. Deeply regretted.

O'LEARY.—On the 3rd inst., at Bath, Thomas Connor O'Leary, M.B., Surgeon-General (retired), aged 63.

RIGDEN.—On the 16th inst., at 231, Brompton-road, S.W., Mabel Cecilia, only child of Walter and Cecilia F. Rigden, aged 6 years.

SMITH.—On the 5th ult., at Waltair, Vizagapatam, India, Margaret Milroy, the beloved wife of James Smith, Surgeon-Major, Her Majesty's Madras Army.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

METEOROLOGICAL READINGS.

Medical Diary for the ensuing Week.

Monday, February 16.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M. each day, and at the same hour.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M. each day, and at the same hour.
ST. MARK'S HOSPITAL.—Operations, 2 P.M., and on Tuesdays at the same hour.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
MEDICAL SOCIETY OF LONDON.—8.30 P.M. Dr. Finlay: A Case of Progressive Anæmia in a man aged forty-five.—Dr. Beevor: Cases of Paralysis Agitans without Shaking.

Tuesday, February 17.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 P.M., and Thursdays at 2 P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M., and on Fridays at 2 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M., and on Saturday at the same hour.
ROYAL INSTITUTION.—3 P.M. Prof. S. Colvin: Museums and National Education.
PATHOLOGICAL SOCIETY OF LONDON.—8.30 P.M. Dr. Norman Moore: Cases of New Growth in the Intestine.—Mr. Lane: Spondylolisthesis and other results of Pressure in connexion with the Spinal Column.—Mr. Sutton: Lung Disease in Wild Animals.—Dr. West: Cases of Mediastinal Tumour.—Dr. Percy Kidd: Sudden Death from Infarction of the Trachea by a Bronchial Gland.—Mr. Lockwood: Large Malignant Growth of Forearm in a Child a year old.—Mr. Bilton Pollard: Renal Cancer associated with Calculi. Dr. Gulliver: Syphilitic Ulceration with Cicatricial Constriction of the Trachea (card).—Mr. Clutton: Large Vesico-vaginal Calculi (card).—Mr. Sheild: Blood-clot from the Surface of the Brain (card).

Wednesday, February 18.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M., and on Saturday at the same hour.—Ophthalmic Operations on Tuesdays and Thursdays at 1.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Skin Department: 9.30 A.M., on Tuesdays and Fridays.
ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M., and on Saturday at the same hour.
LONDON HOSPITAL.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.
GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M., and on Saturday at the same hour. Skin Department: 1.45 P.M., and on Saturday at 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M.
KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.
HOSPITALS ASSOCIATION.—8 P.M. Dr. P. Murray Braidwood: Hospital Ships.

Thursday, February 19.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Surgical Consultations, 1.30 P.M.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and on Friday at the same hour.
NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ROYAL INSTITUTION.—3 P.M. Prof. Dewar: The New Chemistry.
HARVEIAN SOCIETY OF LONDON.—8.30 P.M. Mr. J. H. Morgan: On the Operative Procedures in cases of Cleft Palate, and their Effects upon the Voice.—Dr. C. Theodore Williams: Cases of Emphysema treated by the Compressed Air Bath.

Friday, February 20.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1.30 P.M.
ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.
KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.
SOCIETY OF MEDICAL OFFICERS OF HEALTH.—7.30 P.M. Mr. William Weaver: Sewer Ventilation and House Sanitation.
ROYAL INSTITUTION.—9 P.M. Dr. W. Huggins: Solar Corona.

Saturday, February 21.

KING'S COLLEGE HOSPITAL.—Operations, 1 P.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M.
ROYAL INSTITUTION.—3 P.M. Mr. G. Johnstone Stoney: The Scale on which Nature works, &c.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe, or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

GLYCERINE FOR DRYNESS OF TONGUE AND THIRST IN FEBRILE STATES.

SURGEON-MAJOR S. K. COTTER, in a recent number of the *Indian Medical Gazette*, relates the case of a patient suffering from enteric fever who was awakened every ten minutes by the dryness of his tongue, which was parched and covered with sordes. The tongue was painted with glycerine frequently, and the result was that at the first trial the patient slept almost comfortably, waking up about every two hours with the tongue feeling dry, but not really dry to the touch; after renewed application of the glycerine he at once slept again. In six other cases it has been tried and found satisfactory. Surgeon-Major Cotter does not attempt to decide whether it acts by increasing secretion from the mucous membrane, dissolving the sordes, or making an artificial coating. But, in whatever way it acts, its benefit is vouched for when the tongue is parched during any disease.

G. V. A.—We do not think any danger need be feared, provided the ground be properly kept.

CAFFEINE.

To the Editor of THE LANCET.

SIR,—The use of caffeine in cases of sick headache and other neuroses is not particularly novel—in fact, there is a preparation of it (Bishop's granular effervescent citrate) sold in the shops for such purposes. What is new, and appears to me to have received less attention in this country than it deserves, is the investigation into its action on the heart, which has led Prof. F. Reigel (*Berliner Klin. Woch.*, xxi., 19, 1884) to the following conclusions:—1. Caffeine is a heart-regulating drug, with the same mode of action as digitalis. 2. In suitable cases it increases the power of the heart, slows the pulse, and increases arterial blood-pressure. 3. It produces a rapid increase in the excretion of urine. 4. The indications for its use are the same as those which govern the use of digitalis. 5. Caffeine is most efficacious in frequently repeated small doses. 6. Its action differs from digitalis in that it is much more rapid and entirely free from the cumulative action which often complicates the results of digitalis. 7. Even in cases where digitalis has proved of no service caffeine is nevertheless indicated, and its employment will often be accompanied by favourable results. 8. The simultaneous use of narcotics, especially morphia, with caffeine is not to be recommended. 9. Caffeine, especially in the form of the easily soluble double salts, got by combining it with soda, salts of benzoic, cinnamic, or salicylic acids, is better borne than is digitalis. I will only add that I have found the combination with salicylate of soda an excellent one for exhibition of the drug in cases of cardiac debility following rheumatic fever.

I am, Sir, yours obediently,

Feb. 9th, 1885. H. NELSON HARDY.

X. Y. Z.—There are in existence a large number of institutions for the benefit of the destitute blind. Perhaps the institute situate at No. 2, Young-street, High-street, South Kensington (secretary, H. R. Knipe, Esq.), or that in Somers-town (secretary, Mrs. Stacey, 53, Hilldrop-road, N.W.), would suit the case mentioned. (See Charities Register, Longmans.)

AMENORRHŒA.

To the Editor of THE LANCET.

SIR,—In every case of amenorrhœa in which I have used permanganate of potash the result has been satisfactory, the number of pills given varying. A painless flow always ensued. One of the patients had not menstruated for a period of four months. In the first instance I consider it prudent to correct the general tone of the system, and to stop the drug directly the catamenia appear. The pills used are made by Messrs. Richardson and Co. of Leicester, those containing one grain being quite strong enough to have the desired effect.

I am, Sir, your obedient servant,

Desford, Leicester, Feb. 11th, 1885. R. DURDIN.

COCAINE.

THE *Chemiker Zeitung* remarks that this agent produces in small quantities an excitement of the nervous centres, while in larger doses its effects are of a paralysing character. Aschenbrandt attributes to it very salutary properties for strengthening patients weakened by diarrhœa. E. von Fleischl and Freund have given particular attention to the employment of cocaine in connexion with the cessation of administering morphia. It gradually restores a normal condition in cases of atonic weakness of digestion and nervous stomachic derangements. M. Grasset, in the *Comptes Rendus*, gives various reasons in support of his theory as to the contingent employment of cocaine preparations for bringing about a condition of insensibility unaccompanied by sleep or unconsciousness.

Verax should read Sir James Simpson's book on Homœopathy, or the article in the current edition of the Encyclopædia Britannica, vol. xii.

House Surgeon.—1. No.—2. Yes.

AN EASY METHOD OF APPLYING THE FORCEPS.

To the Editor of THE LANCET.

SIR,—For the last two years I have been in the habit of applying the upper blade of the midwifery forceps in a manner which I have not seen mentioned in any of the text-books, and which is not, I think, generally known to practitioners. All friends to whom I have shown it have stated that the idea was new to them. The usual rule laid down in works on midwifery and taught to students is to bring the patient's hips well out to the edge of the bed previous to applying the forceps; and, indeed, it is frequently necessary to have the hips projecting *over* the edge before the handle can be sufficiently depressed to effect the introduction of the upper blade with any degree of ease. Now, in many cases patients object to this. They do not like to move or be lifted, think they are unduly exposed, or are afraid of falling out of bed altogether, and perhaps when the accoucheur thinks he has his patient nicely arranged, and is proceeding to introduce the blades, she will shuffle away from him into the middle of the bed, and, of course, have to be brought out again. To obviate this inconvenience I proceed as follows:—The patient lies in the usual position in the middle of the bed (if she likes). Having introduced the lower blade in the usual manner, I make an assistant, or the patient herself, separate the legs a little; then, holding the upper blade in my right hand, and bringing the handle well forward between the patient's thighs, I introduce the blade, with its concavity directed forwards and a little downwards, into the posterior part of the vagina, then upwards along the curve of the sacrum until it passes the posterior lip of the os. By now depressing the handle and drawing it gently backwards the blade glides along the head into its proper position, and may be locked. No force is required, no pain is caused, and I have never known any harm result. I recently applied the upper blade in this manner with ease in a case of transverse narrowing where a skilful practitioner had previously failed by the ordinary method.

I am, Sir, yours faithfully,

Dromahair, Ireland, Feb. 9th, 1885. WM. C. LUCAS, B.A., M.B., &c.

Mr. Henry Burwell.—We do not prescribe.

J. F. W.—Patients subject to fits are, we believe, ineligible for admission to idiot asylums.

MEDICAL CERTIFICATES.

To the Editor of THE LANCET.

SIR,—I beg to forward you a copy of a letter I have this morning received from Somerset House in reply to one similar to that which I sent you. It may be of interest to other junior members of the profession.

I am, Sir, yours faithfully,

Chatham Intra, Kent, Feb. 10th, 1885. PERCY F. MONEY.

"General Register Office, Somerset House, London, W.C.,
"9th February, 1885.

"SIR,—With further reference to your letter of the 29th ultimo, I am directed by the Registrar-General to inform you that he has pointed out to the registrar (Mr. Whitehead) that he must not make any objection to a medical certificate of the cause of death because the certifying medical practitioner has inserted therein the words 'as I am informed' in a case where he does not feel justified in stating positively that the death took place on the day named in the certificate. I am to add that the cause of the death in the case of F. M. P—— was entered by the registrar in his register book as 'certified by P. F. M——,' &c.

"I am, Sir, your obedient servant,
"WM. CLODE, Secretary.

"Percy F. Money, Esq., M.R.C.S.E., &c."

MEDICAL PRACTICE IN QUEENSLAND.

A CORRESPONDENT, "*Bread Tray*," desires information in reference to the chances of obtaining a practice in Queensland, and hints as to salaries, &c.

"THE LITTLE NEW ZEALANDER."

To the Editor of THE LANCET.

SIR,—Will you allow me to thank those among your readers who so kindly responded to my appeal in your issue of Dec. 6th, and to inform them that enough money has now been raised to place "the little New Zealander" in the Wanstead Orphan Asylum, where his brother had been already elected. The grandmother also desires me to express her grateful thanks to you and to the many kind friends who have rendered her sympathy and assistance.—Your obedient servant,

Elgin-road, W., Feb. 10th, 1885. STAMFORD FELCE.

THE PREVENTION OF YELLOW FEVER.

G. H. J.—There is nothing new in the information given in a morning paper concerning the prevention of yellow fever by vaccination with an attenuated virus. All that is known on the subject will be found in the last volume of THE LANCET, pp. 545 and 970.

J. J. Monteith.—There does not seem to be the slightest ground for believing that the supposed injury a fortnight previous to the fatal occurrence had any part in its causation. In the absence of history of stricture, pelvic suppuration, or fracture of the pelvis, we can only say that the probable explanation is that the deceased met with some injury by a fall or other mode of violence. The absence of bruising of the skin over the abdomen does not at all prove that the supposed injury was not inflicted in the immediate neighbourhood of the bladder. It does not require much force to rupture the bladder when greatly distended.

"CROWDED OUT."

To the Editor of THE LANCET.

SIR,—Is there a charitable man amongst us? Can adamantine hearts be touched by sympathy for such advertisements as appear from week to week in your columns? Does it not occur to the governors and teachers in hospitals, and to the authorities who are responsible for the admission to our ranks, that there is already a plethora of doctors and doctors' assistants? As one who can speak with authority on this subject, having seen thirteen years of the life of an assistant and locum tenens, I believe there never have existed so many highly qualified men out of employment as there are at the present time. An eminent surgeon writes me:—"I know many well-educated members of the profession who would be very glad indeed to get an appointment of £150 a year. But, alas! I do not know of any such appointments to which I can recommend them." Men have to be content with £100 a year, and find their own rooms and board, nowadays; whereas ten years ago, I remember well, an unqualified assistant could secure £120 and rooms. The gentleman to whom I refer goes on to say: "Would it not be your best plan to go to one of the colonies, where there is less overcrowding than there is in this country and more scope, taking a passage out as medical officer to an emigrant ship?" This good-hearted and courteous gentleman is unaware that at the present time the Earl of Derby has on his books hundreds of doubly qualified men who would indeed be glad to avail themselves of this opportunity. And, again, a premium would be required for an emigrant ship of any other kind than a Government one; and berths are not so easy to secure in the colonies as they used to be before they had their own universities. Capital also is necessary to hold out, even if one managed to pay one's own passage. No; the cry appears to be, Create new universities; keep adding to the ranks of professional men; keep on driving countrymen into the towns, so that the country doctors can hardly exist; and set at nought the fearful poverty that already exists amongst the educated classes, until Communism, dynamite, and revolution shake the very foundation of all civilisation.

I am, Sir, yours faithfully,

Jan. 21st, 1885. SYMPATHY.

CASCARA SAGRADA.

A. G. C. asks if any *confrère* who has had practical experience of the drug can inform him where to procure a really trustworthy preparation of the cascara sagrada, the remedy so much vaunted and advertised for habitual constipation, as the drug in his hands has most signally failed, although prescribed in every way as recommended.

CASES OF CARBUNCLE IN RAILWAY PORTERS.

To the Editor of THE LANCET.

SIR,—During the past twelve months three cases of carbuncle have fallen under my notice, each of these occurring in a railway porter. The patients were all young, healthy-looking, and robust men, and had not been subjected to any very hard work previously; they gave no history of gout, nor had they been tippling. In the case of one, from being a day porter he had recently been placed upon night duty. In each instance the carbuncle was situated upon the nape of the neck. The treatment adopted was merely the routine poultice with tonics, and all speedily recovered. The curious point is that the carbuncle should have appeared in these three men of the same calling, living, as they had been, mostly in the open air, and having plenty of exercise, with good food. Could a strain from carrying heavy weights, bags, &c., in both hands have been the primary cause? Or, perhaps, friction from heavy trunks held upon the back? Or, possibly, some irritant from the hairy coverings of these multifarious packages getting into some slight abrasion upon the neck? Or can it be that there is something peculiar in a railway porter's work which renders him more prone to such attacks?

I am, Sir, yours truly,

Thetford, Feb. 5th, 1885. ALLAN MINNS, L.R.C.P.Lond., &c.

"A CASE OF CÆSAREAN SECTION."

To the Editor of THE LANCET.

SIR,—The short account sent to THE LANCET in statistical form (Jan. 24th, p. 155) was altered in type so that it would appear as if I alone had performed the operation. Perhaps you would kindly allow me to correct this. I was assisted by my senior, Mr. H. Wright, and after I had made the primary incision down to the peritoneal covering of the uterus he completed the operation; so that it was a divided one.

I am, Sir, yours truly,

Hoxton House, Halifax, Feb. 5th, 1885. TH. M. DOLAN, M.D.

SANDEFJORD SULPHUR BATHS.

A RESORT for invalids afflicted with disorders of the gouty and rheumatic type, which appears, from a pamphlet recently published, likely in time to gain the confidence of the medical profession, is the beautifully situated Sandefjord, lying at the extremity of the fjord of that name in the southern districts of Norway. The place is chiefly noted for the existence of a spring of sulphur water, a thousand volumes of which contain rather more than twelve of sulphuretted hydrogen and one of free carbonic acid, together with a large proportion of sodium chloride and other salts of magnesium, potash, and lime.

Dr. Voight.—The paper has been forwarded according to request.

Dr. R. E. Carrington.—The announcement appeared in our last issue.

SANITARY ADMINISTRATION IN IRELAND.

To the Editor of THE LANCET.

SIR,—In your comments on Dr. Flynn's paper read before the Dublin Sanitary Congress you trace the defective carrying out of the sanitary laws in Ireland to the fact that the Poor-law medical officer is also the officer of health. Now, I venture to think that the evil does not rest here at all, as I hold that the dispensary doctor, being constantly brought into contact with the poorer classes, will more often have sanitary abuses brought directly under his notice than would be the case with a special sanitary officer; because the people, looking on him merely as the dispensary doctor, forget his second position, and thus take no pains to hide those sanitary defects which they would certainly do did they remember that he was the sanitary officer. No; I think the real evil lies in fettering the sanitary officer's efforts by subjecting them to the control of an unsympathising board, many of whose members—and especially in small country towns—are themselves the offenders, and who have thus a direct interest in consigning to the waste-paper basket a report which, if it saw the light, would act as a condemnation against themselves, the persons responsible for the carrying out of the sanitary laws. I am, Sir, yours truly,

Feb. 9th, 1885. C. HALY.

FALSE TITLES.

L.S.A.Lond.—The title would not be quite warranted in the circumstances. Our correspondent is well on the way to the legitimate use of it, and should wait. That other men use titles unwarranted by the nature of their diplomas is no satisfaction to those who do not like to sail under false colours.

Executor.—We think not; but it is a legal point we are unwilling to attempt to decide.

LOS ANGELES COUNTY, CALIFORNIA, FOR INVALIDS.

To the Editor of THE LANCET.

SIR,—Having practised my profession near Los Angeles for the last ten years, and having read the letter of the British Vice-Consul of Los Angeles in your last issue, I beg to say I shall be happy to answer any inquiries relative to that country if any of your readers will send a stamped envelope to me. I am, Sir, yours truly,

11, Camden-street, Oakley-square, N.W. JAS. ELLIS, M.D.

Feb. 10th, 1885.

The Publisher cannot hold himself responsible for the return of testimonials, &c., sent to the office in reply to advertisements; copies only should be forwarded.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post-offices letters addressed to initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on page 2, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be addressed.

Advertisements are now received at all Messrs. W. H. Smith and Sons' Railway Bookstalls throughout the United Kingdom and all other Advertising Agents.

Tables of Contents, with the Index of Advertisements, for each Number can be had on application to the Publisher.

Agent for the Advertising Department in France—J. ASTIER, 66, Rue Caumartin, Paris.

The Hunterian Oration

DELIVERED AT THE

ROYAL COLLEGE OF SURGEONS OF ENGLAND,

On Saturday, Feb. 14th,

BY JOHN MARSHALL, F.R.S., F.R.C.S.,

PAST PRESIDENT OF THE COLLEGE.

MR. PRESIDENT AND GENTLEMEN,—John Hunter—the object of our profound homage to-day—bore a name which, especially when uttered within these walls, excites the remembrance of many great achievements. Whilst therefore that name by itself forms a most appropriate introduction and close to an oration to be delivered in his honour, it suggests such a superabundance of material for occupying the brief but important hour which lies before us, and so many details wherewith to embellish the sentences which must be fitted in between the Alpha and Omega of this discourse, that even the most skilled and intrepid orator might well quail before the task.

Before, however, I attempt to grapple with the difficulties of the undertaking, I will, in obedience to time-honoured example, express, in terms I fear too brief, our common regard for the memory of those recently deceased associates, whose special relations to the College entitle them to attention on this occasion. Not that I would willingly ignore the labours of the many Members or Fellows of the College, who, in their respective careers, now closed for ever, have maintained the character of the surgical profession; but the time at my disposal is short, and the claims upon it, as we shall find, are urgent. I must, therefore, content myself with an honourable mention of Robert Druitt, a well-known author and earnest coadjutor in surgical educational work, and proceed to linger a little longer on three special memorial notices of Allen Thomson, Cæsar Hawkins, and Erasmus Wilson.

Professor Allen Thomson was a member of the board of trustees of the Hunterian collection, to which office he was appointed in succession to his friend and former colleague in Edinburgh, William Sharpey. Familiar, from his thirty years' occupancy of the chair of Anatomy in Glasgow, with the splendid collection, chiefly composed of William Hunter's Museum which was purchased for that University, Allen Thomson felt a special interest in our own collection. His inherited scientific tastes, his intimate acquaintance with anatomy, human and comparative, his devotion to embryological research, and his wide knowledge of physiology, made him a true sympathiser with the work and spirit of both the brothers Hunter.

A better-known member of our board of trustees was the veteran London surgeon, Cæsar Henry Hawkins, the latest representative of a family whose name is indissolubly connected with the history of this College. His grandfather, Mr. Charles Hawkins, the son of the celebrated surgeon, Sir Cæsar Hawkins, was chosen the first Master of the Court of Assistants, when the College was incorporated under the Charter of 1800; and he was re-elected to the same office in 1805. The grandson, the subject of this notice, became a member of the College in 1821, was enrolled as a Fellow in 1843, was elected into the Council in 1846, and an Examiner in 1849. Twice after that he occupied the presidential chair—viz., in 1852 and 1861. From 1865 to 1870 he represented the College in the General Medical Council; and from the year 1872 to the day of his death he was, as already stated, a trustee of the Hunterian collection. Thirty-six years ago to-day he delivered in this theatre an admirable Hunterian Oration, and now it has fallen to my lot to record on the present occasion his great usefulness as a councillor, his strict judgment as an examiner, and his exceptional services as twice President of the College.

Begun only five years after John Hunter's death, Cæsar Hawkins's long life of nearly eighty-six years almost bridges over the space of time which separates us from that occurrence. He was partly trained in the famous Hunterian school in Great Windmill-street, and later in life himself gave lectures there. At first a pupil and then for many years assistant surgeon and surgeon at St. George's Hospital, he was acquainted in the early part of his career with Sir Everard Home, John Hunter's brother-in-law, assistant, and literary executor; and, at a later date, with George Babington, who edited Hunter's treatise on the Venereal Disease. A most distinguished member of a distinguished surgical family, who, like himself, had been connected with Hunter's hospital and been honoured by holding Court appointments, Cæsar Hawkins was widely esteemed for his experience and diagnostic skill, his calm and excellent judgment, his high principle, even temper, and urbane manner. He was a favourite in society and an ornament to our profession; and it is both a duty and a pleasure to express here to-day the universal opinion that he was an honour to our College.

As the name of Hawkins has been linked with the annals of the College for nearly the whole of the fast-waning century, so the future history of the College will, humanly speaking, be associated for centuries to come with that of Erasmus Wilson. That active surgeon, the incidents of whose life are generally known, received the diploma of Member of the College in 1831, was made a Fellow in 1843, took his seat on the Council in 1870, and was chosen President in 1881. The story of his early humble means and moderate prospects, of his marked intelligence, industry, perseverance and success, culminating in the acquisition of such vast wealth, and in the exercise of such unparalleled generosity, will assuredly attract much notice from posterity, and will probably strike future generations with greater astonishment than it does ourselves. We, his contemporaries, can scarcely realise the importance of his unexampled bounty to our College. Its influence for good lies concealed in the future; and the responsibility of administering so grand and absolutely unshackled a bequest will be felt to be by no means slight. That its transfer to our charge may be long delayed is a wish we may all express, together with the hope that Lady Wilson may long be spared, to feel pride and solace in the contemplation of her husband's munificence.

It would be selfish and unjust to the memory of this large-hearted man to restrict our regard on this occasion to his splendid donation to the College; for Margate, Epsom, Swanscombe, and distant Aberdeen will continue in remote times to bear witness to his generous thought; many charitable societies, and countless destitute persons, have felt the touch of his benevolent hand, and the whole nation owes to his liberality the actual possession of the great monolith now standing erect on the banks of the Thames. But to revert to what may truly be designated his colossal gift to the College which he loved so well: it may be an idle fancy, but I am fain to imagine that Sir Erasmus Wilson's mind was, consciously or unconsciously, influenced by his familiarity with Egyptian studies, and that he resolved, not indeed to rear an almost imperishable monument for the preservation of his body, but to secure by what we trust may be an equally enduring design for the benefit of his profession and mankind, the perpetuation of his name and fame.

But what concerning the name and fame of John Hunter? for to that theme it is my business now to turn. Happily, under no conceivable conditions of feebleness or failure in these biennial orations can Hunter's brilliant reputation suffer damage or eclipse; but this does not lighten the responsibilities of the orator, who finds himself embarrassed with a multiplicity of subjects, perplexed by the difficulties incidental to selection, arrangement, and comment, and oppressed by the sense of competition with the eloquent and learned addresses which, dealing with the same topics, have preceded his own.

It might seem easy to pursue the well-trodden course of beginning with a sketch of Hunter's career from his cradle to his grave. But, for my part, I have often imagined that there might sometimes be an advantage in reversing the usual order of biographical research and narrative, and, instead of pursuing the downward and smoother course, to follow an upward and more rugged path. As in tracing the history of mankind or the origin of things, the historian or the philosopher employs this retrograde method of investigation, so, at least in an inquiry into the history of a single individual, we might pass from the later and better-known periods to the earlier less known or even unknown moments of his existence. And again, although, as in the case of a river, so in that of a life, it may be more easy, when it has been fully explored, to glide down its unceasing current, yet, in the upward struggle against the stream, with its halts

and delays, we have larger opportunities of becoming familiar with its peculiarities, its shoals and rocks, its rapids and cataracts, its swift strong currents, its gentle windings, its resting-places, and its sluggish pools.

John Hunter's story may, I think, be said to lend itself readily to this mode of treatment, permitting itself to be broken up into successive and variable stages, one very exceptional incident being noticeable even after his death. Thus, just sixty-six years after his lamented decease in the sixty-sixth year of his age, we find his ashes laid, with fitting reverence, in their final resting-place beneath the stones of Westminster's venerable Abbey, in a pilgrimage to which we may read inscribed on perennial brass his distinguishing title, "The Founder of Scientific Surgery." Thence we pass back to the unostentatious obsequies held at his parochial church, St. Martin's-in-the-Fields, and then again, by way of his house in Leicester-square, to that sad and tragic scene at St. George's Hospital, where, upwards of ninety years ago, to the dismay of both friends and opponents, he so suddenly expired. Transferring our views from the inanimate body to the living man, crossing, as it were, the bar between the ocean and the river, I might, did time permit, trace the many fluctuations of Hunter's life and fortunes, and follow these upwards to his humble cot at Calderwood, the place in which he was born.

In regarding the lives of all great men, we naturally marvel at the extraordinary results which flow from such small beginnings, especially when, standing at their graves, we reflect that as living and working entities they exist no more. There also it is that science sees nothing but the lifeless remains, and, divorced from faith, has no further word to utter. But, on the other hand, when science turns her gaze beyond the cradle into the remote past, she perceives an endless chain of living organisms, and, now independent of faith, wonders by what mysterious ordinance—call it creation, call it evolution, call it what men will—an apparently casual protoplastic unit shall grow up to be a man, who, by force of his innate power, and under certain surroundings, shall come to exhibit such pre-eminence amongst his fellow-men, and leave so deep an impress on the world.

The physical and mental qualities which enabled Hunter to accomplish more than any member of our profession has done before or since were not attributes or possessions peculiar to him alone, but his success was achieved by the mode in which he used them. Some men take opportunities, and others make them: it may be said of Hunter that he did both. I do not here propose to analyse the intellectual and moral character of Hunter, or to pass in review his professional, social, and domestic relations. I need not further particularise his work; for this stands revealed in the museum, or is recorded in the museum catalogues, and in his own writings. Neither will I attempt to vindicate his claims as a discoverer, seeing that the task is most difficult in his case, and that very frequently such discussions still remain open to be rediscussed; nor, lastly, shall I endeavour to assert that, in this or that instance, he has anticipated any later views or doctrines, for such suggested anticipations have often to yield precedence to those of some earlier heralds of coming thought. If it be not too presumptuous a method to adopt, I will rather imagine Hunter to be with us in presence this day; and, judging him by his own deeds and declarations, I will try to point out the mental attitude he would probably assume, in regard to the active work and salient opinions of our own times.

Let me first, with this view, direct attention to the Hunterian collection; for it cannot be doubted that Hunter himself would first wend his way to discover what had become of it. We may trust that he would be satisfied that this College should have become the depository of his fine museum, and would feel gratified at the efforts which have been made for its due preservation and extension. He would appreciate the zeal of its successive conservators and their able coadjutors in perfecting its special departments, osteological, craniological, and otological, in opening out fresh fields of observation and in seeking new forms of illustration. He would realise the value of the palæontological specimens added since his day, and the advantage or necessity of arranging side by side extinct with recent animal forms. He would admire the skill displayed in the new articulated and dissected preparations. He would recognise with special thankfulness the labours of our late conservator, Professor Flower, and his assistants, in the preparation of efficient catalogues of the museum. Nor, finally, can we doubt that Hunter would hail with pleasure the prospect that no inconsiderable portion of the Erasmus Wilson bequest will be devoted to increasing the accommodation for the unique collection, of which his own museum was the foundation. I ask pardon for the simplicity of these assumptions, but we must not forget Hunter's affection for his museum. Remembering this, too, I will add, parenthetically, that the increased number of such collections, and their steady improvement in recent times, would not fail to secure the approval of so great a museum-maker.

Speaking of himself, Hunter says, "I do not read many books;" perhaps, therefore, we might suppose that he would be comparatively apathetic as regards the extension of our library; but, nevertheless, I will credit him with the assumption that he would not be wholly indifferent to the interests of that department of the College.

If we next regard John Hunter as an accomplished human anatomist, it needs only briefly to be said that he could have no difficulty in keeping pace with whatever advances have been made, since his time, in the knowledge of the ordinary structure of the human body, as well as of the numerous varieties in arteries, muscles, and other parts, to which it has been shown to be liable.

The immense progress which has been made in the science of comparative anatomy since Hunter's days could not fail to excite the liveliest satisfaction even in his well-stored mind. Countless as are the facts which have been brought to light by the combined efforts of succeeding comparative anatomists, from the time of Cuvier down to the present moment, they would all be welcome to him. To one who had spent thirty years in this field of study, and had himself dissected and described about five hundred species of animals, vertebrate and invertebrate, the diversified new forms and structures which would be presented to his notice could not of course be accepted by him otherwise than as facts. Parts possessing functional significance would be promptly assigned by him to their respective places in his great physiological series. Special structures would be studied by him with even deeper interest, whilst he would quickly learn to appreciate the many novel and unexpected forms which would lie outside his experience, and even beyond his conception.

So, likewise, the wonderful, and, to Hunter, unforeseen revelations of microscopical research, the growth of that new department of anatomy, histology, the insight we have obtained into the origin and development of the tissues and organs of animals and plants, and the extensive acquaintance which has been made with the existence and characters of innumerable minute independent organisms, both in the animal and vegetable kingdoms, would fill Hunter's mind with amazement and delight. It is true that although he employed magnifying glasses in some of his own investigations, he doubted, and even discredited, the results recorded by other observers. Nor is this surprising, for whilst the microscope had even then realised some important discoveries, there were many announcements made which were either perplexing or absurd—the effects of irradiation, diffraction, and dispersion, being sometimes seriously regarded as indications of minute structure. Besides this, Hunter had so large a field of observation in the obvious conformation of the organs of animals open to his reach by the aid of scalpel, scissors, and forceps, assisted occasionally by magnifying powers that he could well afford to disregard the less trustworthy information afforded by the imperfect microscopes of his day. We may be sure, however, that he could not, and, indeed, would not, resist the evidences of structure and organisation displayed by our powerful and exact modern instruments; and we can easily imagine his acquiescence in the truth of a modified cell-theory of the formation of tissues, and in the doctrine of the protoplasmic origin of animal and vegetable life. He would also find much in modern microscopic discovery which would correct, elucidate, or confirm his own guesses at truth. More especially would this be true as to his accounts of the blood-globules, of the growth of bone, of the structure and sensibility of the teeth, the structure and action of muscular fibre, the muscularity of the arteries, the nature of the digestive process, the commencements of the absorbents, and the developement of the chick.

As a physiologist, Hunter was so zealous, unwearied, and accurate an experimentalist that we may be assured of his sympathy with the present refined and stringent methods of research. He cogitated new experiments whilst in his carriage; he had recourse to them in almost every inquiry; he spared no expense in their execution; he planned them

so carefully, and limited them so in their intention, as to avoid failure or fallacy; he modified them so as to adapt them to new occasions; and he endeavoured to learn something from them even when they yielded unanticipated results. He proposed himself to perform many experiments which he did not live to undertake; he suggested to others certain inquiries which he thought worthy of being carried out; and, lastly, he declared that no experimental results could be depended upon which had not been obtained by duly qualified observers. In all these respects, he would be in accord with the best investigators of our time. We may read with a smile his simple experiments on the effects of a decoction of bark, opium, or calumba on the coagulation of the blood, and be amused at the pleasure he expresses at receiving Ramsden's small thermometer, "measuring only one-sixth of an inch wide in the stem," for the prosecution of his experiments on animal heat; but we may be sure that he would be struck with admiration at the complex mechanical and electrical appliances, and at the variety of chemical agents, employed in the well-furnished laboratories of modern physiologists.

It is needless to observe, to those who are familiar with Hunter's writings, that not only as a physiologist but as a pathologist he was a great vivisector; and we may here take it for granted that he would rank himself with those who now claim the right of man, for beneficial purposes or even in the pursuit of knowledge, to attempt to discover the processes of animal life by tests and trials on living animals. Hunter's own numerous experiments certainly threw light on many of these processes. Amongst others may particularly be mentioned those on absorption by the veins, on animal heat, on the effects of heat and cold on animals, on the injection of various solutions into the veins, on artificial respiration with the view of recovering drowned persons, on the ligature of arteries, on the growth of bones, on the division of tendons, on the effects of extirpation of the ovary, and on the transplantation of living parts into other living parts. All Hunter's experiments were necessarily performed without anæsthetics; but we may be sure that he would now approve of their use on every possible occasion. His large views of the unity of the "principle of life," and of the community of organisation and of action throughout the whole animal kingdom, would lead him to disregard the objections of those who insist on the uselessness of experiments on animals, so far as concerns their application to man. On the contrary, I can conceive that Hunter would contend that every fact ascertained concerning the processes of life, whatever the quarter from which it was derived, whether from organisms high or low in the scale, or from animals in health or in disease, must contribute its quota towards the attainment of more perfect knowledge; and that it is to the sum of these efforts at discovery, and not to individual results, that we must look for a scientific justification of this method of inquiry. Hunter distinctly denounces a physiologist who, "like all mere experimenters," "is not satisfied with those [experiments] which are clear and decisive, but multiplies them unnecessarily"; and he adds, "I think we may set it down as an axiom that experiments should not be often repeated which tend merely to establish a principle already known and admitted, but that the next step should be the application of that principle to useful purposes." It may accordingly be inferred that, whilst Hunter would contend for the fullest right of research, he would not be opposed, either on scientific grounds, or (as he was fond of animals, and certainly not desirous of encouraging cruel propensities amongst men) on moral grounds also, to due restrictions in the exercise of this right. Lastly, in reference to this subject, it should be stated that Hunter did not spare his own body, but subjected himself to an inoculation experiment of a very grave character, in order to test opinions on a pathological question, and to put to proof the efficacy of certain variations in treatment. As a consequence of this, he was not completely cured until the expiration of three years. Indeed, it is not impossible that he incurred still later injurious sequels.

In referring to Hunter's physiological experiments, it is certainly remarkable to find that he never performed any with the view of determining the functions of the nerves and of the nerve centres. Yet it is in this branch of inquiry that, since his time, physiology has made such great strides, almost exclusively by means of experiments. Nevertheless, Hunter was not unmindful of the momentous questions herein involved. Thus, in many instances, he touches very closely the doctrine of reflex nervous action; and yet, notwithstanding the significance of his remarks, I will, in accordance with my settled plan, refrain from a suggestion of discovery or anticipation; but I would ask, Would not Hunter be prepared, would he not be delighted, to listen to the explanations which, thanks to Bell, Marshall Hall, Brown-Séquard, and their numerous followers, could now be given him of the mechanism of the various forms of cerebral and spinal sensory and motor reflex phenomena? Even as regards the higher manifestations of action of the great nervous centres, it is certain from various expressions that Hunter would rise to the level of the most advanced physio-psychology of our time.

But I must next proceed to consider the position that we might suppose Hunter to occupy in regard to the zoological, morphological, and biological questions and doctrines of the present day.

Although Hunter's comparative anatomy collection was avowedly made in the laborious search after the relations between structure and function, and was arranged by him accordingly in a grand physiological series, yet he was a practical zoologist, for he had not only formed a large separate zoological series of specimens, but, studying carefully each subdivision of his collection, he observed not only the uses but the gradations of form which the various organs assume in the different groups of animals with which he was acquainted. Seeing how readily Hunter employed his knowledge of the comparative anatomy of the digestive, circulatory, respiratory, and reproductive organs, and also that of the nervous system, in his attempts at the scientific classification of animals, we may easily conceive that he would have accepted the more advanced Cuvierian arrangement founded on wider knowledge than his own, and how truly he would appreciate the various modifications of that system found necessary by succeeding zoologists.

Regarded as a morphologist, we find that Hunter, very early in his career, repudiated the "idea" of confining himself to the description of a single animal; and, as he accumulated his great wealth of facts, he handled them from a morphological point of view with the boldness and ease characteristic of a master. Thus, he not only speaks freely of the "hearts" of insects, the "lungs" of the snail, and of the "brains" of both, and compares the "median nerve cords" of the former to the "medulla spinalis" of the vertebrate animals, but he writes of there being "ten thousand animals without a brain and nervous system to one with them"; and he furthermore indicates the possibility of a nervous substance being diffused throughout the body of the very lowest animals without any visible aggregated centre. He traces the digestive apparatus from its most complex stomach downwards in the animal kingdom to a simple sac, and in describing the comparative anatomy of the fish's ear, he says, "he is inclined to consider whatever is uncommon in the structure of this organ in fishes as only a link in the chain of varieties displayed in its formation in different animals, descending from the most perfect to the most imperfect, in a regular progression." Again, in his estimate of the character of the strong muscular stomach of the Gillaroo trout, he says, it is as "difficult to determine the exact limits of the two different modes of construction to which the names of gizzard and stomach specifically belong, as in any other case to distinguish proximate steps in the slow and imperceptible gradations of Nature." From all this, it is very evident that Hunter could not fail to perceive the bearing of the multitude of facts pointing to similar conclusions, which have been recorded since his time.

But, further still, there is the oft-quoted passage, written in reference to his developmental researches on the embryo of the chick, in which he says, "If we were capable of following the progress of increase of the number of the parts of the most perfect animal, as they are first formed in succession, from the very first, to its state of full perfection, we should probably be able to compare it with some one of the incomplete animals themselves, of every order in the creation, being at no stage different from some of those inferior orders; or, in other words, if we were to take a series of animals from the most imperfect to the perfect, we should probably find an imperfect animal corresponding with some stage of the most perfect." Here he has expressed, in laboured phraseology, a current doctrine of development; and Hunter elsewhere applies a similar train of reflection to the development of tissues.

I now pass naturally to the consideration of the view

which Hunter would, I believe, entertain, as a biologist, concerning the prevalent doctrines of evolution; and I will commence by citing what I think will be admitted to be some noteworthy passages from his writings.

On the general question of the occurrence of varieties in animals, Hunter, in one place, states as a general fact that "Nature is found deviating from general principles." In another place (in reference, however, to sexual adaptations), he observes that "an animal has the power of improving its parts, so as to make them susceptible of such stimuli as are adapted to the disposition of the parts." Again, he states that "as far as my knowledge has extended, there is not a single part of an animal body which is not subject to an extraordinary formation. Neither," he proceeds, "is this a matter of mere chance; for it may be observed that every species has a disposition to deviate from Nature in a manner peculiar to itself." It is true that these latter remarks are applied by Hunter especially to deviations which he says are "more or less monstrous;" but he afterwards, as we shall see, qualifies that term, and the whole context shows Hunter's genuine appreciation of the natural plasticity of animal organisms. More to the present purpose, however, is the following passage: "The propagation or continuance of animals in their distinct classes is an established law of Nature, and in a general way is present with a tolerable degree of uniformity; but in the individuals of each species varieties are every day produced in colour, shape, size, and disposition. Some of these changes are permanent with respect to the propagation of the animal, becoming so far a part of its nature as to be continued to the offspring."

Contrasting again, in another place, the phenomena of variation as they occur in wild and in domesticated animals, to which he obviously paid close attention, Hunter says, "Animals living in a free and natural state are subject to few deviations from their specific character; but Nature is less uniform in its operations when influenced by culture. Considerable variations are produced under such circumstances, of which the most frequent are changes in colour." In a note, he adds, "From the variations produced by culture it would appear that the animal is so susceptible of impression as to vary Nature's actions; and this is even carried into propagation." Still more striking is a note in which, speaking of extreme variations as monstrous, he reflects, "Perhaps the word monstrous is too strong or not exactly just"; and then, he adds this remarkable passage, "It certainly may be laid down as one of the principles or laws of Nature to deviate under certain circumstances. It may also be observed that it is neither necessary, nor does it follow that all deviations from the original must be a falling off; it appears just the contrary; therefore we may suppose that Nature is improving her works, or at least has established the principle of improvement in the body as well as in the mind." Given the additional factor of the advantages bestowed upon individuals by such improvements in the "struggle for existence," and Hunter would have discerned the Darwinian doctrines of "modification in descent," and "the survival of the fittest."

Nor did the question of reversion to the original type, which Darwin so freely discusses, fail to attract Hunter's notice; for in regard to varieties arising from cultivation, he says, "Whether, if left to themselves, they would in time resume their original appearance, I do not know"; and elsewhere he remarks, "I am inclined to think there never is in the wild state a variety in any species of animal in the same country." Furthermore, he makes the important reflection in regard to reversions, that "it would be difficult to prove whether in many of the gradations they are progressive or retrograde." Lastly, he alludes to the necessary adaption of some insects to uniform, and of others to variable climates; and he reflects on the differences of habit which must thus be brought about.

It will be recollected that Darwin employs the term "correlation," as descriptive of certain constant and associated peculiarities and changes in an animal, which may or may not be capable of further explanation; and it is interesting to find that Hunter, without using that general term, which, after all, is only a term, points out as a "general principle" a constant correspondence between the colour of the pigmentum of the eye and the colour of the eyelashes, not only in quadrupeds, but in birds, even when the colour of the skin, hair, or feathers is different. The occurrence of such correlated sexual characters in animals was recognised by Hunter; and his paper on the peculiarities of a hen pheasant which had acquired the plumage of a male is full of reflections and suggestions conceived in the true Darwinian spirit.

The preceding quotations show at least that had Hunter lived now he would have been a staunch evolutionist. We may picture him devouring with eagerness the writings of that school of naturalists, and especially those of Darwin. There is, indeed, in many respects a similarity between him and Darwin; and as during the lives of these two great searchers after Nature's laws the economy of Earl's-court and of Down Cottage bore a certain resemblance, so, in death, it has been the fate of both naturalists to lie in the same consecrated soil.

But it is time that I considered Hunter's mental attitude towards the present conditions of the sciences of morbid anatomy and pathology, and towards that of the modern practice of surgery. A single sentence will suffice to point out that the comprehensive character of our present morbid anatomy collection, which completely overshadows the thousand and eighty-four specimens which Hunter left, the pains which have been taken to make it illustrative of every known form of disease, the labour of love undertaken by our distinguished colleague, Sir James Paget, towards the completion of the corresponding catalogue, and the promise of future extension of the museum would not escape Hunter's appreciative recognition.

Hunter took care to distinguish between morbid anatomy, or the study of diseased structures, and pathology, or that of diseased action, for he correctly defines "pathology" as the "physiology of disease," and it is needless to say that in regard to both of these closely allied branches of knowledge he would admit the important and indispensable service rendered by microscopic research. Moreover, I will assume that he would accept as great generalisations some modification of the "cellular pathology," and the still more recent views on the influence of protoplasmic action in the production of disease.

In his brief but interesting discussion on Tumours, Hunter defines a "true tumour" as an "entirely new part," so that to him the terms "new formation," "new growth," and "neoplasia" would be quite intelligible; nor would he be slow to perceive the scope of the term "metaplasia," the title of a paper read by Virchow at Copenhagen, in which Hunter's name received early and honourable notice. Although the clinical distinctions between a "cancer," a "fungated sore" (probably a sarcoma), and a "scrofulous enlargement" were pretty clearly distinguished by Hunter, yet he expresses himself not always able to decide between them, and he would doubtless acknowledge the help afforded by the inspection of a few of our every-day microscopic sections; whilst many of his other pathological difficulties would be as rapidly dissipated.

As regards the complex phenomena of inflammation, which Hunter had so long and so carefully thought out, it may be said in a word that the modern microscope, whilst adding so much to his knowledge, would elucidate and confirm almost all his sagacious conceptions. Those important agents in the inflammatory processes, the white blood-corpuscles, though perhaps not altogether unknown, were not sufficiently distinguished in Hunter's time. The existence of these being granted, their amœbiform properties, their emigration through the softened walls of the small vessels, their further action on the tissues, their presence in lymph, and their identity with pus-corpuscles, would fill up the details in the Hunterian sketch.

As a clinical observer, Hunter would undoubtedly, as occasion arose, avail himself of every modern method, physical or chemical, and of every new instrument or test, employed in the investigation of disease. In the use of the thermometer he was far advanced; thus, he says, "the standard heat of the human body is about 99°," and he adds, "I believe that degree is pretty regular;" he found that it differed according to the distance from the centre of the body, that it varied between morning and evening, and was diminished at night. He found in a special case that local inflammation could raise the local temperature from 92° to 98·7°, or upwards of 6°, but he correctly concluded that this local elevation could not reach "the standard heat of the constitution" at the time, "nor even to it in parts far from the centre." He observed on one occasion, the fluid of an inflammatory dropsy at a temperature of 104°, and heard, he says, of a temperature of 112° being found in fever. He believed that "nothing can increase that natural heat," "but some universal or constitu-

tional affection;" but he felt that the question was "worthy of inquiry," and he added, "our measurement ..... can be brought even nearer to the truth than is absolutely necessary to be known in disease." How interested he would be in the detailed temperature charts of the present day, as indicating the vicissitudes of the febrile state.

Hunter's list of specific poison diseases contains a rather incongruous assemblage. But that he would seize with avidity the exacter knowledge of the present day, and thereby extricate himself from this confusion, is quite certain. In speaking of the specific fevers due to miasms, he utters this reflection: "It may, perhaps, in time happen that the human race shall be exterminated by poisons alone; but it is more probable that many poisons are extirpated, and that new ones may arise in their stead every day." How this sentence chimes in with modern questionings as to the recent origin of scarlet fever and typhoid, cholera, and diphtheria! How it suggests the sight of Hunter endeavouring to grasp the possibilities of the issues involved in it, gradually gathering up the now well-ascertained facts concerning the organisms which are associated with anthrax and cattle plague, with tubercle and cholera, listening to the suggestions as to the possible modifiable or self-adaptive nature of these organisms, hoping for the means by which they may be checked, or, as he says, "extirpated," and, in short, gazing into that vista of conceivable triumphs over "living contagia," which seem to promise such grand prospects for the future of medicine and surgery!

In now taking leave of Hunter as a general pathologist, I cannot withhold the comment that, as in physiology, so in pathology proper, his views passed beyond the apparent limit of his subjects. Indeed, he associated the two sciences, and, as it were, blended them at their conterminous borders. He said that disease taught us what was health, as well as that health informed us what was disease; and he distinguished a healthy from an unhealthy inflammation. Besides this, he included all animal life in his pathological speculations, as when, for example, he speaks of the vessels at work in the process of absorption having "more of the polypus in them than any other parts of the body;" and it is certain that he recognised the occurrence of morbid processes in plants, as indicated by specimens preserved in his museum, and which he was accustomed to exhibit in his lectures. We may be sure that Hunter would approve the close relations which have recently been established between physiological and pathological investigations, and would applaud any assistance which the College may hereafter offer towards the establishment of laboratories devoted to scientific research.

In the study of one special disease Hunter showed his usual acumen, and, in spite of the changes and subtleties of modern opinion, will rank with the foremost authorities of the present time. After long and continued study and grave experiment, he adopted the view of the unity of the venereal poison, including not only the soft and hard chancre, but even gonorrhœa, in its effects; and now, although the dual theory has for a time held its sway, he would find a strong inclination in the minds of many surgeons to regard the two kinds of sores and their markedly different respective consequences as different manifestations of one poison, in different states or under different conditions. Speaking of the poison of the lues, which is his equivalent for syphilis, Hunter says, "it produces fever which is of the slow kind." "In the first stage of the disease, before it begins to show itself externally, the patient has all the symptoms of an approaching fever. These symptoms, continuing for some days, and often for weeks,..... show that there is some irritating cause, which works slowly upon the constitution." He further suggests that this fever might "exist without the presence of local symptoms." Hunter, furthermore, describes exceptional cases, more or less resembling lues, in which peculiar and aggravated symptoms occur, such as extensive and obstinate sores, and falling of the nails, and which may even end fatally. These, he says, "show as much as possible that new poisons are rising up every day, and these very similar to the venereal in many respects, though not in all." In reference again to syphilitic affections of the bones, he remarks: "Cases sometimes occur in which, after the venereal disposition has been corrected, another disease takes place in the bone, the nature of which will be explained when we shall consider the effects remaining after the disease is cured, and the diseases sometimes produced by the cure." His explanation is that "new diseases" may arise from the mercury alone, or from "different combinations" of the mercurial irritation, the venereal disposition, and the natural disposition, which he assumes may itself not be healthy. In many cases, he suspects that this natural disposition may be of a scrofulous nature; but he would not exclude gout.

Considered as a practical surgeon, present with us to-day, Hunter would find his capital operation of ligature of an artery high up for the cure of aneurysm, in some degree superseded by the improved method of compressing the artery in the same situation. He mentions having, in one of his cases, tried compression, he does not state where or how, but he gave it up on account of the pain produced by it. His own successive improvements in the actual operation, by the more limited exposure of the artery, the non-inclusion of the vein, and the use of one ligature more firmly drawn instead of four applied more loosely and with graduated force from above downwards—all steps calculated to minimise the necessary accompanying suppuration, the evil effects of which he had to deplore—show how gladly Hunter would have adopted the non-irritating silk or the absorbable catgut, cut short and left in a non-suppurating aseptic wound.

As a general rule, Hunter's treatment of wounds was as simple as possible. He employed very few local applications. His advocacy of scabbing by the drying up of all superficial sores was one indication of this, for it commended itself to him as arresting the suppurative process. It is easy to understand how pleased he would be with the modern practice of skin-grafting; and the more serious operations of transplanting, under aseptic conditions, pieces of bone, and recently even of a whole muscle from one animal to another, would have struck Hunter as interesting advances on his own successful attempts to make the cock's spur grow in the comb, and to transplant human teeth.

Hunter's view that surgical operations were often a "tacit" admission of our inability otherwise to accomplish a cure, and that they should always be approached with "a sacred dread and reluctance," would assuredly be qualified now, when in so many new and bold operations so great a measure of success is obtained, and that without the suffering Hunter had to witness, destitute as he was of the welcome aid of anæsthetics.

The great number of novel operations which have been devised since Hunter's time would, no doubt, astonish him; but, on the other hand, it is interesting to find that some of these would be more or less familiar to him. Thus, in reference to external herniotomy, he directs that in congenital hernia the sac should not be opened; he advises the "extirpation" of varicose veins as "very proper, unless the disease is too extensive"; of course, the tunica vaginalis was cut open for the cure of simple hydrocele; he describes minutely the steps of an operation for the cure of unyielding urethral strictures, without or with false passage or urinary fistula, by laying open the distended urethra through the perineum behind the seat of constriction, then passing a fine probe forward through the stricture, dividing this, and afterwards passing a full-sized instrument along the whole canal into the bladder. Acting on a belief, which is shared by many, that cancer is a local, not a constitutional, disease, that it is not hereditary, and only contaminates the system by spreading into it, he advocated as a duty the removal of every enlarged and hardened gland which could be detected in the axilla, in cases of cancer of the mamma, whenever that could be safely accomplished, even those which, he mentions, are often detected when some have been taken away. Lastly, he alludes to lumbar abscesses from which a urinary calculus had been removed, thus justifying a recourse to actual nephrotomy.

As is well known, in reference to the operation of ovariotomy, Hunter says, somewhat brusquely, "There is no reason why women should not bear spaying as well as other animals. It would simply be opening the cavity of the abdomen, which we often do without inconvenience in healthy constitutions." In speaking of peritoneal wounds generally, and the mode in which they are healed, Hunter drew upon his experience as a military surgeon, often alluding to the healing of sword wounds and gunshot wounds of the abdominal cavity, more especially in cases in which no viscus had been wounded. He advised that the stitches of the abdominal suture should not "pass through into the cavity of the abdomen, as they would interfere with rendering the cavity perfect; for, as these continue, suppuration

of the wounds will come on, they acting as a seton, by which exposure of the cavity will be greater, though, perhaps," he continues, "from the irritation they would occasion, adhesions would be formed at the bottom of the wound before this suppurates, which might prevent the admission of air." We perceive here the natural dread which Hunter had of that exposure of a wound or compound fracture to the air which, his whole experience taught him, led to the dangerous suppurative, instead of that milder adhesive, inflammation which ensued in a perfect cavity, or in a simple fracture, or in a subcutaneous or completely covered wound. The full precautions of the antiseptic method being explained to him, he would now have less fear of passing sutures through the whole thickness of the abdominal walls. Supposing suppuration of the peritoneal cavity to have occurred, Hunter observes, "How far in such cases it might appear desirable to make an opening into the abdomen, and throw in warm water repeatedly to wash away the matter, I will not at present determine."

The whole tendency of Hunter's teaching in regard to wounds being to prevent suppuration if possible, it was evidently a sorrowful confession on his part to say, "It appears very difficult to give a true and clear idea of the whole of the chain of causes leading to suppuration." After mentioning ordinary instances of suppuration following exposure to air, he states "these effects might appear to be due to the influence of air"; but, he points out, that air in emphysema of the areolar tissue does not do this, unless the skin be wounded, nor does it do so in the air-spaces or hollow bones of birds, unless these are laid or broken open. "Air, therefore," he continues, "is not the cause of suppuration." Yet Hunter was aware that, before the opening of large abscesses, "patients are generally pretty well, but immediately after that time they become unhealthy and hectic, which continues till death." He recognised that the mischiefs—viz., of hectic and dissolution (i.e., of pyæmia and septicæmia), which followed large wounds, compound fractures, and amputations, appeared "more in hospitals than in private practice, more in large towns than in the country," "often without apparent cause," "frequently in the most healthy persons," "and were rapidly fatal, a result not "due to the sore as an immediate cause," but certainly assisted by it, as the symptoms never occurred "when the sore is healed." For the cure of such cases, he adds, "I do not find anything that has any effect." Yet Hunter saw clearly that "air could convey most poisons," that the air of "warm, moist places was the most impure," and that "the effects of an impure atmosphere are found in gaol distempers and hospital diseases; very few of the former places are ever free from foul air, and most hospitals are more or less affected with it." If, therefore, Hunter had now demonstrated to him that whilst mountain air contains minute organisms in units, country air in hundreds, town air in thousands, and hospital air in tens of thousands, and furthermore had explained to him the relations of organisms of this kind to the fermentative and putrefactive processes, the dangerous or fatal results of the entrance of septic matters from the surfaces of exposed wounds into the blood, and the established efficacy of so-called antiseptics in destroying such organisms, and arresting the decomposition associated with their presence, he would hail the discoveries of Pasteur and the triumphs of Lister with the gratitude they deserve.

In three places in Hunter's writings I find that he uses the now well-worn term, "antiseptic," twice in reference to internal remedies, and once to external applications. In the treatment of hectic, he says, "strengtheners and antiseptics are recommended. Strengtheners are proposed on account of the debility which has evidently taken place; and antiseptics, from the idea of absorbed pus going into the blood and tending to putrefaction." Again, in connexion with the treatment of hectic, he says, "Antiseptic substances have also been employed, such, for instance, as preserve dead flesh; but this is very absurd." The allusion to the external use of antiseptics is in relation to the local treatment of mortification. "Scarifications," he says, "have been made down to the living parts, that stimulant and antiseptic medicines might be applied to them, as turpentine, the warm balsams, and sometimes the essential oils." Such local treatment, however, he regards also as absurd; and, although the agents thus enumerated are all antiseptic, from the point of view of perfect antiseptic surgery, this is true; for putrescence would already have set in. Yet Hunter speaks of tar water and turpentine as often productive of great good as local applications in certain cases, and laments that these and other remedies "sometimes fail, and that we do not possess a sufficient number for the variety of constitutions we meet with." His felt want could now be easily supplied.

There is one feature of the modern practice of surgery which could not fail to be noticed and commented on by Hunter; and at first he would probably disapprove of it, as a departure from the simplicity of the art which he practised. I mean the growth of specialities. But this he would soon find is a necessity as well as a cause of the immense accumulation of facts since his time; and he would become reconciled to it, with all the special instruments and other appliances which modern ingenuity has devised. There is, however, one speciality which, as a great surgeon as well as a great experimentalist, he would be doubly prepared to receive with acclamation—viz., the discovery and use of anæsthetics as one of the greatest boons ever conferred on sensitive beings, whether animals or man.

There are other topics and suggestive passages in John Hunter's writings on which some comment might here be made, but I have selected those most suitable to my purpose. Others necessarily contain certain erroneous statements and conclusions, due to want of more full and accurate knowledge, and occasionally to defective reasoning. Nevertheless, there is hardly a chapter from which some information might not be taken, or some benefit derived. It is also evident that the commentators, in the collected edition of his works published in 1835 that is, just fifty years since — are not unfrequently in error. These works themselves deserve to be re-edited.

How is it that we can look back over the intervening century since Hunter was in his prime and find him so at one with us and ourselves so in harmony with him? This unison neither implies a supreme prescience on his part nor a standstill in science and practice, continuing to our day. On the contrary, there are hosts of facts familiar to us which he did not know, and there have been evolved many opinions and conclusions in advance of his speculations and doctrines. It is, as I have endeavoured to show, because our work and thought to a great extent pursue the lines which he has laid down. The issues in which we join were his; the instruments and weapons may have improved, but the strife and the method are the some. We believe in observation and experiment, and Hunter devoted his whole active life to both; he waited for long years to complete his labours and to mature his reasonings; and though unfortunately interrupted by his sudden death, the main results of his labour are secured. He followed Nature, and endeavoured to detect her ways, for the benefit of mankind. We, in our time, are aiming at the same grand end.

It has often been held as a matter of reproach, in regard to John Hunter's philosophy, that he too palpably personified Nature, looked always for "final causes," and attributed to the living organising principle, or "principle of life," or even to parts of the body in which it acts, a consciousness of its own actions and intentions. The instances in which Hunter does this are very numerous; but when duly considered, his language on these occasions must be regarded as largely figurative, and springing from a craving and a struggle to divine the motives of Nature; and, at all events, they should not be taken as meant for explanations of the vital processes concerned. If, indeed, we consider the most direct evidences of his adhesion to the then prevalent doctrine of "final causes," we discover proof that his thoughts were only partly entangled in the teleological net, and that his mind struck out freely to investigate the modes of action by which the end or final cause was to be obtained. If, for example, in his morphological and physiological studies he sought to explain form by use and structure by its adaptation to function,—and if, in his pathological researches, he accounts for the coagulation of the blood, the occurrence of the adhesive process in inflammation, the formation of pus and its tendency to the surface, the growth of granulations and of new cuticle, the occurrence of eruptions in fever, and other diseased actions, by a reference to their occasionally beneficial effects or salutary ends,— all this did not prevent his admitting that not infrequently these same morbid processes are sadly detrimental in their results, that he often failed to detect what the intention of Nature might be, and that, sometimes, it would have been better if she had acted differently. Here, again, though he sought diligently for final causes to satisfy one want of his mental constitution, yet he never rested there. He desired to know the

"how" as well as the "why," and he therefore occupied himself digilently and constantly in the observation of Nature's ways, and in experiments on her living products and their actions. "It is astonishing," he says, "to see what little curiosity people have to observe the operations of Nature, and how very curious they are about the operations of Art;" and he clearly discerned in all his proceedings that no perception of the end arrived at by Nature really afforded any explanation of the processes she employed. His chase after final causes meanwhile gave a zest to his inquiries, but a close acquaintance with Nature's actual work was needed to find food for his intellectual appetite. If, too, we reflect on his modesty in the expression of his opinions, as when he uses such phrases as "I conceive," "I suspect," "I do suppose," "I am apt to suppose," and others of a like character, and on his horror of definitions, which, he says, "of all things on the face of the earth are the most cursed," on his occasional avowal of ignorance and candid statement of facts adverse to his opinions, and on his incessant promises to satisfy himself by experiment,—I think we may conclude that in the fields of both science and practice, his mental constitution was as philosophical as the work he performed in the world is far-reaching and gigantic.

I have now, Mr. President and Gentlemen, almost fulfilled the duty assigned to me; but I have as yet said not a word of John Hunter's personality. He is described to us as having been "about the middle stature, of a vigorous and robust frame, and free from corpulency; his shoulders were high and his neck short, his features were rather large and strongly marked, his eyebrow projecting, his eyes were of a light colour, his cheeks high, and his mouth somewhat underhung. In dress he was plain and gentleman-like, and his hair, which in youth was of a reddish-yellow and in his latter years white, he wore curled behind." In Reynolds's fine portrait, which, as is usual on these occasions, is placed before you, he is represented sitting, self-contained, abstracted from all his surroundings, absorbed in pleasurable thought. Looking at his face, we may well agree with the great master of physiognomy, Lavater, who said, "that man thinks for himself;" and we may feel that he appears equal to the conception and accomplishment of all he actually did. About a century has elapsed since that picture was painted; and Hunter at one time, when engaged in observing the effects of cold on animals, indulged, like some others, in the fancy that a man might be frozen for a time, and then, as he says, "by getting himself thawed every hundred years, he might learn what had happened during his frozen condition." "Like other schemers," he adds, "I thought I should make my fortune by it; but this experiment undeceived me."

I have to-day endeavoured to revive him, not in body, but in spirit, conversant with our present position in science and in practice, and supposed to be studying a vast crowd of additional facts, contemplating fresh generalisations and putting new methods to the test. Our acknowledged teacher, he would find much to learn; but what true teacher is not eager to be taught? Hunter would be an apt student, in harmony with us in thought and plan, hand to hand with us in work and deed. His fitness to understand all that we have since discovered, and to co-operate with us in all our novel doings, constitutes, in truth, his best claim to the grand title, recorded above his grave, "The Founder of Scientific Surgery."

And, now let me repeat, before I retire, that I recognise our presence here to-day as an act of homage to our great predecessor. I desire also to express the pleasure which I have experienced in the preparation, and, I may add, in the delivery, of this oration. The hour at my disposal is rapidly expiring, and the moment is at hand when the ever oncoming future, traversing the imaginary film of time, which is the only real present, will be for ever merged beyond it in the past; and I am well content that my last utterances from this place, spoken between the two eternities, should be the name of that great biologist, that illustrious master in our noble craft, John Hunter.

THE HEALTH OF WELLINGTON.—The report by Dr. Mereslith, medical officer of health, on the urban district of Wellington for 1884, states that the year was, like the one before it, marked by a considerable prevalence of illness of diphtheritic nature. The rate of mortality was 20·59 per 1000, and of births 27·35 per 1000.

ON VISCERAL SYPHILIS.[1]

BY J. S. BRISTOWE, M.D., F.R.S.

CASE 1. *Tertiary Syphilis; Obstruction of Abdominal Vena Cava, with great Dilatation of Veins in the Walls of the Chest and Abdomen; Large and Nodulated Liver; Affection of Left Elbow and Knee; Incomplete Recovery.*—On the 8th of last November, Rachel W——, a woman forty-two years of age, was sent to me by Dr. Shackleton of Norwood, and received under my care into St. Thomas's Hospital. She was married about twenty years previously, and some little time after attended as an out-patient at St. Bartholomew's on account of ulcerated sore-throat, which was of considerable duration. Her first child was born two years after marriage, and three others at successive intervals of two years, all four having reached the full term, but dying either in the act of delivery or within a few minutes after birth. The fifth and only subsequent child was born eight years ago, and is in good health. There is no definite history of syphilis or of any cutaneous eruption. For the last seven years she has suffered from ulcerated legs. About three years ago her abdomen became enlarged, and after a time shrank again. Two years ago she had what she calls an attack of rheumatic fever, and about the same time began to suffer from pain in the epigastrium, increased by food, and attended with vomiting, and then she first noticed that the veins in the abdominal and thoracic walls were enlarged. How long they had been enlarged, or enlarging, she did not know; but it was at this time her attention was first specially attracted to them, and thinking they were not natural, she compared herself with one of her female friends. The attack of so-called rheumatic fever lasted some few weeks, and several joints were inflamed. All of these got well excepting the left elbow, which has remained painful, tender, and swollen ever since. The pain in the epigastrium, the loss of appetite and sickness, have also continued, and indeed have gradually got worse; the epigastrium, moreover, has become swollen and very tender, and latterly a tumour has been recognised in it. About three months ago she vomited a good deal of blood. Six weeks before admission the left knee became swollen and painful. The swelling, she says, has diminished, but the pain in it and tenderness have been getting more severe. On admission, she was a thin, dark-complexioned, pale, cachectic, anxious-looking woman, complaining of weakness, loss of appetite, sickness, pain, and tenderness in the epigastrium, pain and tenderness in the left elbow, and pain, tenderness, and swelling in the left knee. On looking at the anterior surface of the abdomen and chest I was at once struck by the large development of the subcutaneous veins. Tracing these from below there were two large ascending tortuous veins (the epigastric), of which the right was the larger, and fully equalled an ordinary cedar pencil in diameter; these, somewhere about the level of the umbilicus, divided into branches, and at least seven such branches (having the average diameter of an ordinary quill pen) ran up tortuously, but diverging, so as to be disposed fan-like all over the anterior surface of the upper part of the abdomen and the chest, as high as the clavicles. It was assumed that the ascending cava had been obstructed, and that the blood returning from the lower extremities was carried mainly through the epigastric veins to the internal mammary and intercostal, and so conveyed into the superior cava. A strong venous hum could be heard through the stethoscope in most of the dilated veins contained in the walls of the thorax. The abdomen was full, especially in the epigastric region, and for the most part soft. But the epigastrium itself was occupied by a large, hard, and very irregular tumour, which descended to within an inch and a half of the umbilicus. This appeared to be continuous with the liver, and moved very slightly with the respiratory movements. The liver did not rise higher into the chest than normal. The epigastric region was extremely tender. The spleen appeared to be somewhat enlarged. There was no evidence of intra-thoracic disease. The left elbow-joint was fixed in the semiflexed position; it was hot and slightly swollen, from thickening of the soft parts only, very tender, and the attempt to move it caused much pain. The muscles of the

[1] A paper read before the West Kent Medico-Chirurgical Society on Feb. 6th, 1885.

upper arm were distinctly wasted. The left knee was also kept partly flexed; it was swollen, hot, and tender, and could not be moved without provoking extreme pain. The swelling, which was considerable, was mainly of the tissues around the lower end of the femur. There did not appear to be any effusion into the joint. Tongue clean and moist; pulse 100; respiration 24; temperature 99·8°. Bowels regular. Urine containing a trace of albumen. Catamenia absent for five years.

When I first saw her I assumed that the patient was suffering from some form of malignant disease, probably sarcoma. Although my view did not fit in with all the facts of the case, it seemed to explain the more important of them. I thought that the primary tumour had taken its origin among the retro-peritoneal glands and obstructed the vena cava, and so led to the dilatation of the superficial veins; that in the course of time it had grown into the mass which was occupying the epigastric region, and so had caused the pain and tenderness in that situation, together with the loss of appetite and vomiting; and that the recent affection of the bone, limited as it seemed to be to the lower end of the femur, indicated a secondary growth in the bone. With respect to the epigastric tumour, I did not venture to express a decided opinion as to whether it was all a mere outgrowth of the deep-seated glands, or in part due to secondary implication of liver or stomach, or both. My view did not account for the rheumatic attack of two years previous, or for the condition of the left elbow, which from the little enlargement it had undergone could scarcely have been the seat of sarcoma. Taking this unfavourable view of the case, I treated the patient with sedatives, such as bromide of potassium, opium, and cannabis indica, tonics, and dieting. Little change took place in her condition during the next six weeks. She often complained of epigastric uneasiness and pain; but her sickness was very variable, and intermitted at times for a week or more. She never vomited blood, and she took food on the whole fairly well. Her elbow neither improved nor got worse; but some effusion took place into the knee-joint, which remained immovable and extremely tender and painful. But at the end of this time she was still apparently quite as well in her general health as she was on admission, and there was no evidence that the epigastric tumour had increased in size; she had certainly not lost flesh. On Dec. 21st my young and able colleague, Mr. Pitts, saw the case with me. He examined the joints with extreme care, and came to the conclusion that there was no affection of bone, that the swelling was due to inflammatory thickening of the soft parts, and suggested that this affection might be syphilitic. He pointed out, moreover, as adverse to the opinion I had formed, that secondary malignant disease of long bones occurs for the most part in the shaft, and not in the joint ends. It was now, for the first time, that we elicited the suggestive fact that her first four children had all died at birth, and that she had formerly suffered from ulcerated sore-throat for a long time. The progress of the case hitherto had led me more and more to question the sufficiency of the view I had taken of its nature, though I had not yet definitely discarded it, and I hailed Mr. Pitts's suggestion, which seemed to me applicable to the whole series of lesions, and to be approved by the recognised facts of the case. Moreover, as I shall presently show, the adequacy of the explanation was proved to me by my own previous experience of constitutional syphilis. I at once prescribed ten grains of iodide of potassium and forty minims of solution of perchloride of mercury, to be taken three times a day. Nearly seven weeks have elapsed since my patient has been subjected to the new plan of treatment, and I think the results confirm the correctness of the amended diagnosis of the case. The elbow and knee have slowly but uniformly improved, and are now practically well. The tumour in the epigastrium has appeared to me to have become somewhat, smaller and softer, and certainly less painful and tender, and the superficial network of veins has undoubtedly become less marked. Also she has improved remarkably in flesh, strength, and spirits; but she still suffers from occasional vomiting. I may mention here that on the day on which she was ordered to take mercury and iodide of potassium she was, during the morning, unusually low-spirited, could not collect her thoughts, and said she saw double, and in the evening had a fit, in which she was rigid and insensible for a couple of minutes, and on which followed severe headache and rigidity of the right leg, continuing for some hours. She has had no cerebral symptoms since. I need scarcely add, perhaps, that according to my present view the patient has had some gummatous growth in the neighbourhood of the vena cava ascendens, and involving the vein either by pressure or directly, and that the epigastric tumour is probably due to a series of gummatous tumours developed in the substance of the liver. The reasons which had prepared me readily to alter my views of the nature of the case just narrated, and to accept as a general explanation the suggestions made by Mr. Pitts in reference to the affection of the joints, have already been given. But the reasons which decided me were partly my personal knowledge of the occasional abundant diffusion of the later syphilitic lesions, and their tendency to ape the characters of disseminated cancer or sarcoma, partly my vivid recollection of some remarkable cases which collectively presented an almost exact counterpart of this woman's case, and something more.

I now proceed to give the details of the more important of the cases to which I refer. The first of them is one in which a syphilitic patient was attacked with symptoms of mediastinal tumour; from which, under suitable treatment, he recovered. The point of special interest, however, is that he had as one of the signs of tumour temporary obstruction of the superior cava, or of both innominate veins.

CASE 2. *Tertiary Syphilis; Symptoms of a Mediastinal Tumour, with Obstruction of Vena Cava or both Innominates, removed under Influence of Antisyphilitic Treatment.*—Liberty V——, a labourer, forty-three years of age, came into St. Thomas's Hospital, under my care, on May 5th, 1880. He was a sailor for some years, then a navvy, and has drunk hard. He had syphilis in 1857, but was not treated for it. In 1869 some bone exfoliated from the hard palate; and in 1870 several of the upper teeth came away with their alveoli. Three years ago he fell from a building in course of erection, and injured one of his testicles, which was removed a year later. For twelve months he has had a cough, at first dry, latterly attended with expectoration. But in other respects he was well up to about three weeks ago, when he observed some swelling of the neck and eyelids, which came and went, but on the whole increased, and dilatation of veins in the neck and chest, and blueness of the ears. In a short time these symptoms were followed by difficulty of breathing and dysphagia. He has complained of a sense of heat in the head and neck, but of no pains or uneasy sensations referable to the chest. He is a spare and in many respects a healthy-looking man. He is suffering from dyspnœa; has been unable to lie down for two or three nights, and now has to sit up in bed. He states that he could not swallow at all yesterday, and now he can only swallow fluids, and these with difficulty. His face is swollen and congested, especially the eyelids, which, with the conjunctivæ, are livid. The ears also are livid, and the lips, though in a less degree. The neck is œdematous, and the veins, especially those on the right side, are much dilated. They do not pulsate. The superficial veins of both arms are a good deal dilated, but there is no œdema. There is great enlargement of the veins over the back and front of the chest, as low as the nipples. The larger ones form a prominent and coarse network, very visible and full at all times, but starting into strong relief whenever he coughs. There are also over the chest many pencils or groups of smaller veins, and knots corresponding with their points of union, or with the points at which the deeper veins become superficial. No venous dilatation and no dropsy appear below the waist. There is no sign of cardiac affection, and no definite proof of disease of the lungs. Fairly good resonance exists everywhere, excepting that it is thought there is slight relative dulness at the right apex; but there is no abnormal vocal fremitus or resonance, and the breath sounds (which are somewhat prolonged during expiration) are in other respects fairly healthy. There is no tubular breathing, rhonchus, or crepitation. The cough, which comes on at times in paroxysms, is loud and metallic, and attended with scanty expectoration. There are no physical signs of tumour or of aneurysm in the chest and no enlarged glands in the neck. The abdominal viscera seem free from disease, excepting that the urine presents a trace of albumen. The inguinal glands are somewhat large and hard. The soft palate and part of the hard palate have been destroyed, leaving a large triangular gap of communication between the mouth and nose, in consequence of which his voice is nasal and indistinct. It was evident that the patient was suffering from obstruction either of the inferior cava or both innominate

veins, and that the affection causing this was, directly or indirectly, causing difficulty of swallowing and orthopnœa. An intra-thoracic tumour was the obvious explanation. My former experience would have led me to suspect the presence of a malignant growth or of an aneurysm, even though I could not detect any local evidence of one or the other; but the clear evidence he presented of having suffered from constitutional syphilis made me hope that the intra-thoracic tumour might prove to be syphilitic, and I at once ordered him to take ten grains of iodide of potassium three times a day. For a couple of days there was no change for the better; in fact, if anything, he got worse. He was unable to lie down; he was hungry, but could only with difficulty swallow fluids in small quantities; the lividity and œdema of the face and neck were considerable; and his paroxysmal cough was frequent and distressing. Then he began gradually to improve. The lividity and swelling of the face first diminished; then his dyspnœa and cough became less and less severe; then he began to swallow with increasing facility; and, lastly, the dilated veins seemed to shrink and become less visible. Marked diminution of lividity was noticed on the 8th and 9th, and no lividity whatever remained when he left the hospital. About the same time his breathing and cough began to improve, although there was for a time a liability to paroxysms of dyspnœa and of cough. On the 17th it was noted that he was much better in these respects; and there was no trace of anything of the kind when he was discharged. About the 12th or 13th he was able to swallow soft solid—for instance, bread-and-milk; and on the 17th was taking fish without much difficulty. The dilated veins also gradually shrunk; and at the time he left the hospital the knots and pencils of small veins had almost completely disappeared, and the larger veins in the thoracic walls were scarcely noticeable, except when the patient coughed, at which time they started into well-marked relief, and formed a network in front and behind, the vessels measuring perhaps from an eighth to a sixth of an inch in diameter. He left the hospital on May 31st, at which time he expressed himself as feeling perfectly well, and better than he had done for years. The only apparent trace of his malady was the persistence of dilated vessels. I may add that during his illness he had some extravasation of blood into one of his conjunctivæ; and that on the 15th and 16th he was observed to perspire pretty freely on the right side of the face, while the left remained dry. At this time, too, the left pupil was larger than the right, though both acted to light. A day or two later the surface temperatures were taken on the two sides, when it was found that that of the right temple was 95°, and that of the left 96°; that of the right axilla 93°, and that of the left 94°. On the 25th the temperatures on the two sides were equal. Throughout his illness his temperature was normal or a little subnormal. The patient has called on me frequently since. I have seen him within the last few months. He has never had a recurrence of the above symptoms; and when stripped no one would, under ordinary circumstances, observe any enlarged veins in his chest walls. When, however, he coughs, they start out at once into relief, just as they did at the time of his leaving the hospital.

(To be concluded.)

ULCERATION OF THE APPENDIX VERMIFORMIS, FOLLOWED BY PYÆMIA.

BY G. S. ROBINSON, M.R.C.S., L.R.C.P. LOND.,
SURGEON, SCOTS GUARDS.

IN his extremely interesting clinical lecture, published in THE LANCET of December 6th, 1884, Dr. Fenwick makes the statement that in ninety-five cases of ulceration of the appendix vermiformis which he has collected "abscess of the liver was only found to be present in one;" and further on remarks that "when we remember how commonly pyæmia takes place in cases of deep abscess of the limbs, we cannot but be surprised at the small number of cases recorded as following perforation of the appendix." I hope, therefore, that the following notes of a case which recently came under my care, and in which pyæmia was a prominent feature, may be interesting. I may remark that in many respects it will be found to closely resemble the first case described by Dr. Fenwick as occurring in his own practice.

Private W. Y——, aged nineteen, a recruit of only two months' service, was admitted to hospital on October 24th, complaining of great pain in the abdomen, accompanied by nausea, shivering, pains in the back, and headache. He was in a very weak condition, and stated that he had felt ill for the previous three days, but had not reported himself sick, as he was about to purchase his discharge from the service, and was anxious, therefore, not to be sent to hospital. He had never been in India or elsewhere abroad, and had had neither ague nor dysentery. There was no history of syphilis, and no family history of tubercle. On examination the tongue was found to be very foul in the centre, with red tip and edges; skin hot and dry, though at times there were copious perspirations; bowels constipated. The temperature on the evening of admission was 101°; pulse 110, hard and jerky. He complained of pain and tenderness on palpation over the whole of the abdomen, but chiefly over the epigastric region; this, however, was not markedly increased by pressure. Slight gurgling was noticed in the cæcal region, but there was no dulness or induration. The abdomen was distended and tympanitic. Hepatic dulness was slightly increased in front, and there was marked dulness posteriorly up to the angle of the scapula, with tubular breathing, and increased vocal resonance. There was, however, no further trace of lung disease elsewhere. Splenic dulness was not increased. The patient was ordered half an ounce of castor oil (to be taken immediately), a saline mixture (an ounce to be taken every four hours), and fomentations. His condition remained unaltered till the 31st, constipation continuing obstinate, and the temperature showing very irregular rises and falls, accompanied by rigors and sweating. Pain was referred more to the head than the abdomen, and little sleep was obtained.

On the 31st (eight days after admission) jaundice supervened, the urine was high coloured, and the motions (which were few and scanty) were very pale. The following day the temperature, which was 99·8° in the morning, rose to 106·2° in the evening, being accompanied by increased violence and number of rigors. The pulse was only 104; the patient lying on his back in a drowsy condition, but without delirium. There was increased headache, but little abdominal pain, and the legs were not drawn up. There was no dyspnœa or other lung symptom.

March 2nd: Jaundice more marked; frequent attacks of nausea, with vomiting of bilious matter. Temperature fallen to 102·8°. Quinine in two-grain doses, with saline mixture every fourth hour, light linseed poultices to abdomen, and milk and soda water were ordered.—5th: Symptoms remain the same, but are less severe; jaundice subsiding; temperature and pulse lower.—6th: Temperature has fallen to 101°; pulse very weak (100); respiration 36. Tympanites less, and little or no pain in abdomen. Urine increased in quantity, less highly coloured, and containing some albumen. Bowels have not been moved since the 3rd. Ordered six drachms of castor oil.—8th: Last night violent purging set in (without the oil being taken), bowels acting twelve times. The motions are small in amount, of pale colour, and very offensive. Temperature reduced to 100°, pulse 120, respiration 36. Rigors, followed by copious sweating, occurred several times in the twenty-four hours. Very little sleep at night. Ordered two ounces of brandy in small quantities.—Evening: Much weaker. Temperature at 3 o'clock rose to 101°, and at 6 o'clock it was 104·4°; pulse 140; respiration 46. Tongue dry and brown; sordes forming on the lips; purging, which was less during the afternoon, is recurring. Ordered a mixture of sulphuric acid with opium, one ounce three times a day; brandy (half an ounce) every second hour.—9th: Rallied somewhat during the night, obtained some sleep, and says he is much better; no headache, and but slight pain in abdomen. Temperature fallen again to 100·4°; pulse 120, soft and compressible; skin dry and harsh. There is nausea, but no vomiting since yesterday evening. Bowels moved four times in twenty-four hours; motions of pale-yellow colour, and containing curdled milk. Jaundice appears more marked to-day. General condition is drowsy, but when aroused he will answer questions intelligently; there is no delirium. Takes nourishment well. Brandy continued.—10th: Passed another good night, and appears brighter. Temperature 100·8° (last night 104·4°); pulse 112, and improved in character; respiration 32. Bowels acted

five times since yesterday; stools contain more bile and are less offensive. Vomiting has ceased.—11th: Condition unaltered; passed a bad night, but there is no increase of weakness. Temperature keeps down (100·8°); pulse 108; respiration 28. Diarrhœa is again troublesome; bowels moved eight times, chiefly in the night. Takes quinine in three-grain doses thrice daily; also the acid and opium mixture.—12th: Condition less favourable. Obtained little sleep last night. Temperature 102·8°; pulse 120; respiration 32. Bowels moved six times since yesterday morning; motions yellowish-green and containing mucus, but no blood. Urine is less highly coloured, slightly acid, and containing some albumen. One ounce of brandy every third hour. Takes milk, beef-tea, and soda water well.—14th: Condition unaltered; little sleep at night, but obtains some in the daytime. Temperature 100°; pulse 116; respiration 40. Bowels moved eleven times; abdomen much less distended, and there is but little pain; rigors continue, and are of increased duration and severity, the cold stage lasting about ten minutes. The following figures show the fluctuations of temperature noted in the course of the twenty-four hours:—At 9 A.M. 101·8°; at 3 P.M. 99·8°; at 6 P.M. 101°; at 7.30 P.M. 102·8° during the cold stage of a rigor; 8 P.M. 104° during the hot stage; at 9 A.M. 99·8°. Ordered quinine in five-grain doses three times daily and ten grains of kino and opium powder at 8 P.M.—15th: No alteration in symptoms, but increased weakness. Pulse 120, small but regular. Diarrhœa and sickness less. Passed a good night.—16th: Weakness and emaciation are increased; drowsiness more marked. The patient lies on the right side chiefly and does not appear in any pain.—17th: Steadily sinking; slight delirium.—18th: Died quietly at 5 A.M. this morning.

Autopsy, thirty hours after death.—The body was emaciated and jaundiced, but well developed. Lungs: Some old pleuritic adhesions together with recent lymph over the lower third of the right lung, which was congested. No abscesses and no trace of tubercle in either lung. Heart natural. Abdomen contained about half a pint of straw-coloured fluid. Evidence of subacute peritonitis of some duration throughout, but most marked over the cæcum. Intestines bound together rather firmly, and omentum and mesentery much thickened. Examination of intestinal tract showed ulceration within the appendix vermiformis, which was much thickened, congested, and of a dark colour. It was dilated into a small abscess cavity the size of a walnut, near its termination, and perforation appeared to have occurred about the middle. No foreign body could be detected. Cæcum and ascending colon were congested, but there was no ulceration. Small intestine also slightly congested and the glands were thickened, but without ulceration. The mesenteric glands were enlarged, and the seat of numerous small abscesses. Liver was studded throughout with abscesses, varying in size from a pea to (in one case) a small orange. The largest one contained about two ounces of thick creamy pus, and was seated in the posterior and inner part of the right lobe. This portion of the liver was enlarged in comparison with the rest of the gland, which was only slightly increased in size. Gall-bladder empty and contracted; on passing a probe (with some difficulty) this condition was found to be due to an abscess pressing on the duct, and thus preventing the flow of bile. Stomach much distended and containing a large quantity of bilious fluid. Spleen and kidneys slightly congested, but otherwise healthy.

Kensington Barracks, W.

ON OTOLOGY IN RELATION TO GENERAL MEDICINE.[1]

BY H. FRENCH BANHAM, M.A., M.D. CANTAB.

IN calling attention to ear symptoms and ear diseases as they occur in connexion with ordinary medical practice, I shall first deal briefly with those cases in which, the organ of hearing being perfectly healthy, the well-known ear symptons of tinnitus, giddiness, and deafness arise. By tinnitus is to be understood subjective sounds having no relation to any external cause. In regard to auditory hallucinations I need say but little; they form frequently the prelude to, or exist as symptoms of, serious psychical disease; they occur also as auræ epilepticæ, and in the latter case they are said to begin as crude sensations of a confused noise, which soon resolves itself into musical sounds or vocal utterances. I have of course met with cases where auditory auræ have been complained of, but of the interesting mode of development that I have just mentioned I have met with no confirmatory evidence. There are certain persons of a highly sensitive neurotic temperament in whom ear disturbances arise as the result apparently of simple excitement. I was called lately to a case of this kind, occurring in a person of more than ordinary intellectual culture, and who had previously been under my care (as had also other members of her family) for neuralgia. On returning from church one Sunday evening, the service having been one of more than ordinary interest and excitement to her, she was seized with a ringing in the ears and with giddiness of such a pronounced character that she was unable to ascend the staircase without assistance. She told me that she had had previously similar, but less severe, attacks. When I saw her the only peculiarity that I could detect was undue distinctness of hearing on the affected side. She had slept badly for a day or two previous to this seizure, but was by no means in an exhausted condition. She benefited greatly by bromide of potassium, and the only similar attack that has occurred since was a few days back, when she was excited by the unexpected visit of an old friend.

In reference to the causes producing tinnitus, quite apart from any actual disease of the ear, it may be said that their name is legion, although a great many are no doubt due to disturbances of the circulation. This is illustrated by the circumstance that cardiac diseases, aneurysms of the arteries, and especially those in the immediate neighbourhood of the ear, the pressure of tumours upon the internal jugular vein (influencing indirectly the discharge of blood from the labyrinthine veins), and the wearing of garments constricting the neck, will frequently give rise to noises in the head. Mr. Field called attention to its existence in some cases of Bright's disease, and attributed it, and perhaps with truth, to increased arterial tension. It is also occasionally present in anæmia, gout, in lithæmia independently of gout, and in cases of nervous prostration accompanied with phosphatic alkaline urine. Some cases are reflex in origin, and are due to irritation of the digestive organs or of the pharynx, gums, and teeth, &c. Tinnitus assumes a vast variety of characters, such as hissing, ringing, cracking, buzzing, rushing; and these sounds are sometimes rhythmical, synchronous with the pulsations of the heart, and often closely resembling cardiac bruit. The rhythmical variety is no doubt due to some form of arterial disturbance, but it is not necessarily a symptom of any gravity, and may arise temporarily from excitement, errors of diet, and especially the indiscreet use of alcohol.

The question of deafness apart from ear disease is one of great interest and importance, and should find a conspicuous place in such a paper as this. The subject, however, is one that cannot be satisfactorily dealt with in a few words, and therefore I shall be compelled to content myself with little more than an enumeration of the conditions under which it arises. It may be of interest to mention that it was present and formed an important symptom in a case of glioma of the pons that I brought before the members of the Sheffield Medico-Chirurgical Society last winter, and upon which a post-mortem examination was afterwards made; and it exists also in a man with a cerebral tumour now an in-patient at the Sheffield General Infirmary. It is confessedly difficult to distinguish between labyrinthine and cerebral deafness; but in the cases just referred to the diagnosis was aided by concomitant symptoms, and the presence of optic neuritis. Without any primary disorder of the labyrinth deafness may occur from disease affecting the brain and its membranes, involving the acoustic centres, the nucleus, root or stem of the auditory nerve.

I wish now to call attention to those cases of ear disease occurring in the course of other maladies, or which arise as a consequence of certain morbid conditions of the system. We might perhaps classify these disorders in the following manner according to their causation: (1) Reflex; (2) extension of morbid (inflammatory) processes; (3) certain constitutional conditions, as syphilis, tuberculosis, which lend to the structures of the ear a special vulnerability.

1. Under the first of these heads may be named acute catarrh of the tympanum, which is liable to arise in infancy and often in association with painful dentition. It is not

[1] A paper read before the Sheffield Medico-Chirurgical Society on Nov. 20th, 1884.

unlikely that the connexion of the otic ganglion with the inferior dental nerve on the one hand, and the carotid plexus on the other, by which the blood-supply to the tympanum is influenced, may explain the frequency with which the morbid conditions that I have referred to are associated the one with the other. In many cases, in strumous or otherwise unhealthy subjects, the ear disease, brought about in the manner I have stated, plays only an intermediate part, and the inflammation passes from the muco-periosteal lining of the tympanum to the dura mater which is continuous with it through the petro-squamosal fissure, a fissure which although more or less closed in later life is patent in infancy. This extension that I have named may possibly go far not only to explain many of the eclampsic seizures of infancy during dentition, but also many of the inflammatory ear attacks by which one or both ears are practically destroyed. Cases are also recorded of sympathetic hyperæmia of the ear in sympathy with the digestive organs and the uterus.

2. There is probably no more frequent cause of disease of the tympanum than that of extension to it of inflammatory processes from the pharynx to the Eustachian tube. Any one of the diseases of the middle ear may originate from pharyngitis occurring in association with measles and scarlet fever. The most obstinate purulent diseases of the ear arise from scarlet fever, in which frequently the tympanic membrane is destroyed and the functions of the labyrinth so far affected as that the patient is rendered deaf in one or both ears, and with the dreadful possibility also at any time of mastoid disease, caries, pyæmia, or severe cerebral complications arising. I may here add, as showing the serious importance of these suppurating diseases of the ear, that of seventy-six cases of cerebral abscess collected by Gull and Sutton, twenty-seven, or more than one-third, were traceable to ear disease.

3. In regard to the important part which is played by various constitutional conditions, the strumous, the tubercular, the syphilitic, and the gouty, in the causation of ear disease, time will not allow me to say much. Birch-Hirschfeld, in his article on Scrofula in Ziemssen's "Cyclopædia of Medicine," remarks that "scrofula is at the bottom of the largest number of cases in which weakening and destruction of the function of hearing have taken place during the age of childhood," and that "the large number of scrofulous individuals found in deaf and dumb asylums is to be explained by these facts." There is, I think, no doubt that a very large proportion of the intractable cases of ear disease following scarlatina and measles are due, in the main, to a scrofulous diathesis. Syphilis may affect the organ of hearing in many ways. Condylomata or ulceration of the external auditory meatus may be due to it, or a mucous catarrh of the middle ear may result from an extension of the throat affection along the Eustachian tube.

Let us for a moment consider in a general way of what the sensory nervous supply to the ear consists. The auriculo-temporal division of the fifth distributes branches to the external canal and the outer layer of the tympanic membrane, and the auricular branch of the vagus also ramifies in the external meatus. Within the tympanum is situated the tympanic plexus, composed of fibrils from the glosso-pharyngeal, sympathetic, and fifth nerves, and the chorda tympani passes through the drum cavity in a more or less exposed condition. It requires only the recognition of the elaborate nervous connexions of the ear to see at once that it is an organ disease or irritation of which might be most prolific in the development of reflex phenomena. At present we have little data to guide us to the actual frequency with which nervous reflex symptoms in infancy and adult life are due to affections of the external auditory meatus, the middle ear and the labyrinth. Cases, however, have been recorded of epilepsy and other disorders depending on such affections, and I can add to the number from observations of my own. The attention of the profession generally has scarcely been sufficiently directed to this subject. While speaking of the effects transmitted to the ear from difficult dentition I incidentally drew attention to the close relation existing between the dura mater of the brain and the muco-periosteal lining of the tympanum, a relationship which, though always intimate, is especially important in early life while the petro-squamosal fissure exists. It is essential that this anatomical connexion be borne in mind in this part of my paper, while I am dealing, however cursorily, with the secondary effects of ear disease. Under any circumstances the dura mater is separated from the lining of the tympanum by a very thin layer of bone, so thin as to be almost transparent, and perforated abundantly for the passage of vessels. Again, lying in close proximity, and separated only by thin osseous walls from the tympanum, are the internal carotid artery, the lateral sinus, the internal jugular vein, and the superior petrosal sinus; and here again the thin bony septum is alike perforated by vessels. The last anatomical fact that I will mention is that the upper part of the tympanic space communicates directly with the mastoid cells. The facts that I have alluded to painfully suggest that disease once established in the middle ear must expose the sufferer to risks of such terrible complications as embolism, thrombosis, phlebitis, septicæmia, cerebral abscesses, purulent meningitis, and acute tuberculosis. That these serious, and indeed fatal, complications arise in connexion with suppurative disease of the middle ear is well known, but whether the fact is recognised sufficiently is, I fear, doubtful. What proportion of cases undiagnosed, or regarded from the want of fuller knowledge as being typhoid or brain fever, are really due to some of the foregoing? The question, from its nature, cannot be answered; but I surmise that the proportion is not an inconsiderable one. These cases are no doubt often very obscure, and even when pyæmia is recognised the connecting link of ear disease is often overlooked. In the last report of the Clinical Society eight fatal cases are recorded of brain disease arising from disease of the ear.

I cannot help thinking that even a partial consideration of ear symptoms and ear diseases brings with it the reflection that the ear is by common consent too much removed from the general practice of the physician and surgeon. Specialism has advantages and disadvantages, and I desire to be no more alive to the one than to the other. In certain departments we are indebted to specialism for many valuable instruments of diagnosis and treatment; but it has the drawback of obscuring the far-reaching influences which bear upon the organ to which the specialist devotes himself, and of closing the eyes of the general practitioner to the initial cause of many of the serious secondary and reflected symptoms that he is called upon to treat. It is a serious thing to lose sight of the fact of the integrity of the human body and of the mutual interdependence of all its parts. Error of the kind I allude to is excusable on the part of the ignorant; but the medical profession (enlightened students, and observers of nature, as we ought to be) should be scrupulously careful in no way to foster such mistakes. For many operations no doubt fingers and eyes untrained to the special work are a disadvantage; but if we travel too far along the lines of specialism we risk more serious dangers. The more general the knowledge the more accurate should be the diagnosis; the whence and whither of any disease should be better traced out before the eyes of the man whose vision is not too limited. It is, however, of vital moment to the advantageous employment of this wide-spread knowledge that there be a dexterous manipulation of every instrument for ascertaining the precise nature and extent of the local mischief; and so long as there is failure here, the specialist will be still supreme. I have already inferentially intimated the fact that I believe in specialism, so far as regards those operations where peculiar manipulative skill is necessary, and roughly speaking where very small instruments are required to be handled. Specialism to this extent is necessary, but beyond this it need not extend. According to the bent of a man's mind he may naturally have a special liking for certain subjects, but for anyone deliberately to confine himself exclusively to a small specialty, and for the profession to encourage him in this, is to sanction a system fraught with danger to the best interests of the public. Whence arises what I may venture to call the evil of a mischievous specialism, and how is it to be met? The ignorance of the public is largely the pabulum on which it fattens, but who is responsible for its existence?

I would respectfully submit that I think in our medical schools the specialties are too far separated from the ordinary routine work of the hospital. Diseases of women and children, of the skin, of the eye, ear, and teeth are so far removed that a student may obtain all his certificates and present himself for his final examination without ever having attended in any way the practice of these departments. Again, I would venture to express the opinion that the examining boards unduly favour specialism by eliminating most or all of these subjects from their examinations, and at the Colleges of Physicians and Surgeons I believe a candidate would feel himself hardly dealt with if he were called upon to diagnose a case requiring the use of the ophthalmoscope, the laryngoscope, the tuning fork, or ear speculum.

ON THE

TREATMENT OF URETHRAL STRICTURE.[1]

BY F. SWINFORD EDWARDS, F.R.C.S. ENG.,
SURGEON TO THE WEST LONDON AND ST. PETER'S HOSPITALS.

SINCE the time of John Hunter and Sir Everard Home the rational treatment of stricture of the urethra has steadily but surely advanced. This I think will be readily allowed after perusing a work on "Strictures in the Urethra" by the latter surgeon, published in the beginning of this century. Then in cases where the passage of a bougie was an impossibility, it was the practice to cauterise the stricture with nitrate of silver by means of a bougie armée. One case is recorded where this procedure was repeated 1258 times in the space of fifteen years, ending singularly in a fortunate result—i.e., the passage of a bougie into the bladder. But this treatment was an advance upon the method which preceded it, and which consisted in pressing a bougie against a stricture, the object being to cause ulceration followed by perforation.

[The views of Otis on the calibre of the normal urethra were here reviewed, the author stating that he entirely coincided with the conclusions of this surgeon. Attention was drawn to cases of chronic urethral discharge depending upon a small or contracted meatus in which all the symptoms had cleared up after freely incising the orifice. The fact of a penile fistula being due to a stricture which readily admitted a No. 22 French bougie, and which consequently had not been diagnosed, was instanced as showing how important was the recognition of anterior strictures of large calibre. In classifying strictures, Dittel's was mentioned as being one of the best, though for practical purposes the following was recommended. Setting aside contractions due to spasm, organic strictures were divided into two chief classes: anterior and posterior, or strictures of the penile and of the fixed urethra, these being either of large or of small calibre; passable or impassable, eccentric or concentric. Traumatic, complicated, and congenital were mentioned as subvarieties. The so-called "temper" of strictures was dwelt upon as greatly influencing the subsequent treatment.]

The vast majority of stricture cases which come under notice are submitted, at all events, I suppose, in the first place, to gradual interrupted dilatation, and rightly so, as this is the simplest and safest of all methods. There is no doubt that a cure follows in a certain proportion of these cases, and relief in many more. In private practice most cases are amenable to this treatment; in hospital, however, one meets with more aggravated examples of this disease, so that the percentage of cases in which other means have to be resorted to is larger. Recent strictures, when not at the meatus, are most benefited by this. When the obstruction is due to a wart or bridle—Dittel's first class of stricture—one or two passages of a bougie may suffice for a cure. Some years ago a gentleman came to me with the following symptoms: narrowing and twisting of the stream, increase in frequency of micturition, and gleet. I passed a bougie very gently, but this was followed by two or three drops of blood; after repeating this once or twice, all his symptoms disappeared. I suspect his trouble was due to what old writers called a caruncle; in other words, a wart or outgrowth of granulations, which was broken down and removed by the passage of the bougie.

Respecting the treatment by gradual interrupted dilatation a good deal of one's success will depend upon the kind of bougie used and the way of using it. For this purpose there is no better instrument made than the French bougie olivaire.

In cases of stricture of large calibre in the penile urethra I am now trying Otis's method. With his dilating urethrotome the contracted parts of the canal are dilated and cut until it is restored to its normal dimensions, which have been previously ascertained by means of the urethrometre. Should there be a stricture at the bulbo-membranous junction, it is left for future treatment if necessary. I say advisedly "if necessary," for this subpubic stricture which may be impassable is sometimes due to spasm dependent upon the anterior strictures. Otis and his followers believe that this is usually the case. I am not prepared to go so far as this, but I certainly think that before we subject a patient to the risks—for though small they are real—of a cutting operation in the fixed urethra, we ought to eliminate all chance of this being spasm due to co-existing anterior contractions. I have had two or three cases where this treatment has been attended with the best results, others which are still under treatment are making satisfactory progress, though in one case epididymitis and in two urethral rheumatism has been set up. It must be borne in mind, however, that these cases were treated as out-patients.

So much, then, for strictures in the penile urethra. Concerning those in the deeper portion, which are often of small calibre, with the orifice situated eccentrically—accompanied, perhaps, by a good deal of fibrous thickening—they are frequently impassable to most varieties of instrument. To treat such cases successfully one needs a selection of fine filiform gum elastic bougies, either straight or with the ends spirally twisted. It is to this little instrument I would especially direct attention. Armed with one or two of this form of bougie, one may enter almost any stricture, however eccentric or tortuous it may be. These bougies are made with a screw attached in order to act as pilots or conducting bougies to catheters or some form of urethrotome or divulsor. Having in a given case succeeded in passing a guide, several courses are open to one. It may be left in for a time until the stricture dilates, admitting a larger instrument; this being the method known as continuous dilatation. Personally I do not mind leaving a bougie in the urethra for an hour or two when it is necessary to dilate a stricture for the purpose of passing a urethrotome; but to treat a stricture by tying in a bougie for days does not commend itself to me. I have seen it set up cystitis, which has at once been relieved by performing an internal urethrotomy. It also not unfrequently causes urethritis, abscess, and epididymitis, accompanied by considerable constitutional disturbance. Again, a catheter having a screw attached may be made fast to the "pilot," and pushed on into the bladder, thus giving relief in cases of retention. If the stricture be of long-standing, and at all extensive, the guide bougie being *in situ*, I think it is as well to perform an internal urethrotomy at once, after the manner to be described immediately; but if there is any reason to believe that the stricture is a dilatable one, or for the sake of procuring immediate relief without having recourse to a cutting operation, Harrison's modification of Holt's divulsor might with advantage be employed. By this instrument is accomplished what may be called "rapid dilatation," neither the stricture nor the urethra being ruptured, as is the case with Holt's instrument. I used this dilator quite recently in the case of an old man who came to St. Peter's with incontinence, dribbling by day and night. He could only micturate in drops. There were several strictures, one being subpubic. Through this I could pass nothing, until I took a fine corkscrew guide bougie which fitted Harrison's dilator. There was no doubt that the sooner this old man was able to empty his bladder the better for him, so the pilot being in position I screwed on the dilator and passed the three smallest bolts without causing much pain. On removing the instrument I asked the patient to pass urine. He was delighted to find that it came in a stream; though small, it was a better performance than he had accomplished for many a long day.

[The method of performing internal urethrotomy by means of Teevan's modification of Maisonneuve's urethrotome was here described, and the practice of tying in a catheter after the operation condemned.]

I have performed internal urethrotomy between twenty-five and thirty times, and have assisted in about a hundred more. The results I have obtained have been very good, as all my patients have been able to micturate in a good stream, other symptoms which before had troubled them being completely relieved. I am not content unless I can pass a No. 22 bougie or catheter after the operation through the deep urethra; and this size must be maintained, or sometimes increased. If there are anterior strictures large in calibre, they are, as before said, best dealt with by means of dilating urethrotomy. I find, on looking through the register, that since I have been attached to St. Peter's Hospital—i.e., for the last three years—we have had 142 cases of internal urethrotomy, with three deaths only. Two of these cases died from causes, not likely to occur again; and in the third I do not think that death was due to the operation, at least not directly. I will briefly narrate these cases.

In the first case, that of a man aged thirty-five, who had

[1] Read before the West London Med.-Chir. Society, Jan. 2nd, 1885.

suffered from stricture for fourteen years, and had undergone both supra-pubic puncture and perineal section, there was some difficulty in passing a catheter after the urethrotomy, so an instrument with a larger blade, No. 26 instead of No. 22, was used for the second time. A rigor followed soon after the operation, and the patient died collapsed on the following morning. The second fatal case was one of traumatic stricture from which the man, aged forty-four, had suffered for twenty-six years. In this case also difficulty was experienced in passing the catheter after the section, in fact it is doubtful whether an instrument was passed into the bladder after the urethrotomy. A severe rigor occurred after the operation, followed by suppression of urine. From this he recovered sufficiently to get up daily. This was a fortnight after the operation. Four days afterwards he suddenly died. The post-mortem revealed suppurative nephritis. The third case—the only fatal one out of sixty-five operations during the departed year—died from shock due to hæmorrhage which was severe enough to call for external urethrotomy. How this arose I cannot say. It is the only case in which I have seen bleeding worth mentioning follow the use of this instrument when the blade is of a size to cut to 22 of the French scale.

Let me here mention a fact which has struck me, and which is that in the three cases just recorded some difficulty was met with in the after introduction of a catheter; I have also noticed that this has been the case nine times out of ten where suppression has followed. I would suggest that where the catheter does not pass easily, it is better to desist or even reinsert the urethrotome than use any force or prolonged manipulation. Immediately before or after the operation it is a useful practice to give two grains of quinine in a little hot brandy-and-water, in order to prevent shock and rigors. Harrison of Liverpool recommends three minims of aconite for this purpose, but although I have given it an extensive trial, I have not found it of much use. Anæsthetics are not as a rule required, though, if the stricture is likely to be difficult to cut through, ether should be given.

Cocaine bids fair to be of great use in urethral surgery; at present its high price precludes its being generally employed in hospitals.

After the operation it is important that the patient should be kept warm between blankets, with hot bottles to his feet; the sooner a free diaphoresis is established the better. The chief thing to guard against is urethral fever, ushered in by rigors, and accompanied sometimes by suppression. There is generally a rise of temperature after this operation, but if the kidneys are acting no alarm need be felt. I have known the temperature to run up to 104° more than once, and yet be normal after the lapse of twenty-four hours. If, however, suppression occurs, prompt remedies are necessary, together with careful and assiduous nursing. There is a patient of mine in the West London Hospital at the present time who is recovering from this complication, thanks to Mr. Menzies, the house-surgeon, and to the careful nursing he has had. The best means at present known for combating this condition is the hot-air or vapour-bath, with large doses of digitalis. Dry cupping to the loins and turpentine enemata have also proved most useful. The patient's strength must be supported, for which the half-hourly administration of brandy, &c., may be necessary. The diarrhœa and vomiting which are sometimes present should not be stopped unless excessive; the alimentary canal is simply doing vicariously the work of the kidneys.

The instrument the use of which has just been described cuts from before backwards, as do also those of Voillemier, Hill, Maisonneuve, Gouley, and Harrison. As I prefer Teevan's, I will not take up time by describing the others. Of the instruments which cut in the opposite direction the best are Watson's and Civiale's, the latter, or Sir Henry Thompson's modification, being the better known of the two. In his recent lectures at the Royal College of Surgeons Sir Henry extolled its use. It has, however, certain drawbacks, some or all of which have been recognised by the following authorities—Coulson, Gouley, Berkeley Hill, Teevan, and Harrison.

Touching the splitting of strictures by Holt's method, my experience has been limited to cases which have relapsed after this treatment, and of which I have met with not a few. Of these I may say that the strictures are of a more severe form than those which have not been submitted to operation. Between the years 1870 and 1880, 115 cases were split in the Westminster Hospital, with three deaths, according to Mr. Davy. Comparing these statistics with those I have given, internal urethrotomy as performed at St. Peter's undoubtedly carries off the palm, although Holt's method bears favourable comparison with internal urethrotomy as performed at University College Hospital; for Erichsen in his new edition mentions that in seventy-six cases during five years there were four deaths, eight cases of perineal abscess, besides extravasation in one and epididymitis in four cases.

As to external urethrotomy, I will here only say that as this is a more serious operation than that of internal, it ought to be limited—except possibly in some cases of traumatic stricture, accompanied or not by urinary fistulæ—to cases of impassable stricture, which ought nowadays to be but few and far between, looking to the great improvement which has of late years taken place in bougies and other urethral instruments.

In conclusion, I would direct attention to the importance of being able to recognise the presence of slight strictures—i.e., strictures of large calibre situated in the penile urethra,—such a condition being quite sufficient to keep up a gleet, to cause irritability of the bladder and other urinary troubles, not forgetting spasmodic stricture in the deep urethra. If this anterior stricture of large calibre admits of treatment by bougie—i.e., if we are able to restore the urethra to its normal size by this means,—well and good. But if not, no harm, but immense benefit, will be derived from dilating urethrotomy in careful hands. For organic strictures in the deep urethra, where dilatation either cannot be resorted to or does not succeed, I would recommend internal urethrotomy with Teevan's urethrotome.

A CASE OF CHOREA OF FIFTEEN YEARS' STANDING IN A MAN AGED FIFTY-SIX.

BY J. C. M'LEARN, M.D.,
MEDICAL SUPERINTENDENT, HOLBORN UNION INFIRMARY.

SOME attention having been lately given to the subject of chorea in the aged, I hope that the following case may be of interest.

T. M——, aged fifty-six, a gardener, was admitted into this infirmary on June 3rd, 1884, suffering from chronic chorea. His parents, brothers, and sisters were all healthy, and there appears to have been no rheumatism or nervous disease in the family. He is a widower with two sons, aged respectively fourteen and twenty-two years. The elder is healthy, but the younger is said by the friends to be fidgety and to have involuntary movements of the feet and shoulders, especially noticeable whilst sitting reading. He has not had rheumatism, has the heart sounds normal, and is to all appearance in good health. The patient, although born in Scotland, has resided about London for the greater part of his life, and has never been abroad. He had always enjoyed good health, has been a very temperate man and a non-smoker. He has not suffered from acute rheumatism, fits, or gout, but had been troubled with muscular rheumatism, which took the form of lumbago. About fifteen years ago he became "nervous," walked staggeringly, had startings of the hands, and, when sitting, shuffling of the feet, but in a slight degree. These symptoms, the onset of which was very gradual, and for which no cause has been assigned, continued with but slight increase until about four years ago, when his wife died somewhat suddenly after three days' illness. This event caused him to appear dazed for a time, and greatly aggravated the symptoms—so much so that he has never been able to work since, and has from that date continued to get worse. The patient is a man of medium height, fairly nourished, with greyish beard and bald on the top of his head. On looking at him as he lies in bed, he presents the appearance of constant irregular movements which are typically choreic. These movements affect the arms and head more than the trunk and legs. The head is turned from side to side, and frequently lifted from the pillow as though he were trying to look at his feet. The facial muscles, especially those around the mouth and the occipito-frontalis, are frequently in action. The arms, particularly the right, are constantly in motion, being pushed down and retracted, the wrist and elbow being lifted from

the bed, and the pronators and supinators brought into action. The fingers are extended and flexed in turn, the thumbs also performing these movements in the same jerky manner. The shoulders partake in most irregular motions, and are, with the upper part of the trunk, frequently lifted off the bed. The legs and feet are also affected, but in a less degree. All these movements, which in character are irregular, jerky, fidgety, and often seem half purpose-like, may occur in a few seconds, many of them being synchronous, and they are almost incessantly repeated while under observation. They stop only during sleep, but are lessened in frequency and severity when no one is near, and are increased again when any one notices him or speaks to him. He generally lies during the day with a handkerchief over his face, so that he may not be disturbed nor have the movements increased by seeing the other patients walk about. On asking him a question he tries hard to reply, but some little time usually elapses before he can articulate, and then not at all distinctly, though sometimes he will pronounce several words well and rapidly. His tongue is not protruded involuntarily, and when put out is not withdrawn with a jerk. He answers questions rationally, but his memory is not good. He is also rather irritable, and gets greatly excited at trifling things, but he has no dementia. He is somewhat deaf, but his eyesight is good, and he reads a great deal. Ophthalmoscopic examination showed the discs to be normal, but the veins were swollen. He perspires frequently and profusely, and complains of being made warm by the movements, so that he only wears one blanket whilst his fellow patients use three. His temperature has been often taken, but has only reached as a maximum 99·6°. The tongue is clean, and he eats his diet, an ordinary meat one, fairly, feeding himself, but should anyone speak to him whilst doing so a mishap is almost sure to occur. His bowels are regular, and he has not been sick or had vomiting since his admission. He has perfect control over both bladder and rectum. The pulse is about 80, and there is no cardiac murmur, the heart sounds being normal. The respiration ranges from 14 to 18 per minute, and is broken and irregular. He cannot stand alone, and when trying to walk with assistance his gait is shuffling, jerky, and halting, the heel usually touching the floor first. He has diminished plantar reflex on tickling the soles. Ankle clonus is absent, but the patellar reflexes are exaggerated. He often complains of headache, and of slight pains in the calves of the legs, and suffers from a feeling of weariness from the muscular movements, which otherwise are painless. The cutaneous sensibility is not impaired. His urine averages about twenty-two ounces per diem, and has a specific gravity of 1034. It is turbid, which microscopical examination shows to be due to urates. It is acid in reaction, has no albumen, only a trace of sugar, and no indican. The urea is diminished in quantity, being only 242 grains per diem. The movements have not improved under treatment. He has had arsenic and iron for some months, followed by bromide of potassium and tincture of conium, and lately sulphate of zinc was ordered in three-grain doses. The ether spray has also been applied over the spine.

Remarks.—The case seems to carry out the view of Charcot that this form of chorea is incurable, but is at variance with his opinion that it is always associated with dementia. The following points may be noticed:—1. The movements have existed for fifteen years. 2. The movements were much increased by an emotional cause—i.e., the shock caused by his wife's death. 3. The absence of heart disease and of rheumatism, except the muscular variety. 4. The diminution of urea, though the profuse sweats might partly account for the small quantity present in the urine. 5. The probability that the son may at some future time be attacked by chorea in a marked form.

Holborn Union Infirmary.

CITY OF LONDON TRUSS SOCIETY.—The annual general meeting of the governors of this Society was held on the 4th inst., when it was stated that the number of patients relieved in 1884 was 9248, the highest ever recorded by the Society, and 122 more than the number relieved in 1883, bringing up the total of patients relieved at the close of last year to 405,426. The number of instruments supplied was 9305. The income amounted to £5810, exclusive of the balance brought forward from 1883, as against £3990 in the previous year.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas at morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Procemium.

MANCHESTER ROYAL INFIRMARY.

TWO CASES OF SPINAL INJURY.

(Under the care of Mr. THOMAS JONES.)

THE two cases of spinal injury which Mr. Thomas Jones records will be found very interesting. The first case, one of dislocation in the lumbar region with paralysis of the lower extremities, was apparently unaccompanied by fracture, no evidence of it being obtained from manipulation of the part under anæsthetics, either before or after reduction; nor was there the line of hyperæsthesia commonly found in fracture at the junction of the paralysed and unparalysed parts, and which was noted in the second case of injury to the cervical region, where from the form of the vertebræ, dislocation, though rare, is more often uncomplicated by fracture than in any other region of the spine.

CASE 1. *Dislocation of the Spine in the Upper Lumbar Region; Complete Paraplegia; Extension of the Spine under Chloroform; Recovery; Remarks.*—William B——, aged twenty-three, was admitted on May 8th, 1884. While unloading timber, some heavy pieces came violently in contact with the posterior and lower part of the neck. At first he was driven into a sitting posture, and then the back was bent to such an extent that the forehead touched the knees. When extricated from this position, a deformity of the back existed, and the patient was not able to move his legs. He was taken to the infirmary without delay, and within an hour of his admission Mr. Jones saw him with Mr. Pollard, then the resident surgical officer. On examining the back, a large, soft, fluctuating swelling was found occupying the lumbar region. Through this swelling the spines of the vertebræ could be detected on deep pressure. By tracing them from below upwards an abrupt depression between the first and second lumbar vertebræ was found, and at the bottom of the depression the spines of the vertebræ above could be felt. The continuity of the column was therefore interrupted in the upper part of the lumbar region by separation of the first from the second lumbar vertebra. It was also noted that the patient bore unmistakable evidence of severe shock, and that there was complete motor and sensory paralysis in both lower extremities. The upper limit of the paralysis was not well defined. From the symptoms it was concluded that a partial dislocation had been produced by extreme flexion of the spine, and it appeared very desirable, if possible, to reduce the deformity and restore the suspended functions of the cord. With this object the patient was placed under the influence of chloroform and gentle extension of the spine made. This was done by means of two long towels fixed to the thighs immediately above each knee, while an assistant steadied the chest and upper part of the spine. During the progress of the extension the patient was lying upon his left side, so that any change in the position of the vertebra could be more readily witnessed. After a few seconds' extension a sudden jerk was experienced, and the vertebra regained its position with an audible click. When the action of the anæsthetic had passed off, it was found that motion and sensation in both legs had been restored to a considerable degree. The restoration was more complete in the right limb. The patient complained of much pain in the region of the injury, which was decidedly relieved by a quarter of a grain of morphia hypodermically administered.

May 9th.—The patient is able to move both legs; sensation very good. There are, however, patches of numbness, which are more extensive on the left than the right side. Retention of urine; catheter consequently employed, and urine drawn off three or four times in the twenty-four hours.

11th.—Area of impaired sensation on the left side reaches as high as the middle of the thigh. The urine is alkaline and

ammoniacal; bladder washed out daily with a weak solution of boracic acid. Several bullæ have made their appearance on the dorsum of the left foot. These may possibly be attributed to the application of strapping and bandage, with the view of applying a weight to steady the limb, or they may be indicative of trophic changes.

14th.—No more bullæ have appeared. Numbness, less marked, is now confined to the left thigh. Has much greater power in the limbs, and is now able to lift the left leg off the bed. Has considerable pain when the bladder is distended. Troublesome constipation, with pain in the rectum.

June 15th.—Gradual improvement since the last report. A Sayre's plaster jacket applied. While this was being done patient felt faint, and in the evening the temperature rose nearly two degrees. Urine, now faintly acid, contains a small amount of albumen.

20th.—Faradaic current to the legs, muscles react readily. Patient got up for the first time, but could not stand without assistance.

22nd.—Complains of headache and pain in the back. He looks ill. The temperature reached 102° in the morning, and 103° in the evening.

25th.—Faradaism continued. The muscles supplied by the anterior crural nerve on the right side, and by the sciatic on the left, do not react so readily as the others.

July 1st.—The febrile attack, which has lasted for nearly ten days, has subsided; the patient expresses himself as feeling much better, and as being free from pain.

12th.—Each time the limbs are galvanised pain of a severe character is experienced, especially in the legs.

15th.—Has had another relapse, the temperature again reaching 103° on two occasions. The galvanism is suspected of being the cause of this attack. Plaster jacket removed; spines of second and third lumbar vertebræ prominent.

23rd.—The patient has passed a good night. The temperature normal. For the first time he is able to pass a small quantity of urine, but this can only be accomplished by the employment of considerable force. Daily washing of the bladder is continued.

Aug. 2nd.—Still another relapse, and this time no likely cause can be discovered. This attack lasted five days, and during its progress the highest temperature, 103·4°, was recorded. He complained of intense headache and some sickness; the face was flushed and the pulse very rapid (130); there was also pain in the lumbar spine, extending into the dorsal region; great hyperæsthesia over the same parts, and very severe pain in the lower limbs, especially in the knees. His urine contained phosphates and a considerable quantity of pus.

8th.—The temperature again normal. The pain has ceased, except in the sole of the left foot, where he has very intense shooting pains and great hyperæsthesia.

16th.—Renewal of the pain in the back; temperature last evening 102°; is normal again this morning. The electric reactions of the muscles of the legs were as follows:—The right thigh (anterior half)—weak current: Vastus internus, rectus, and sartorius contract less strongly than vastus externus. Left thigh (anterior half)—weak current: Rectus and vastus externus contract powerfully; sartorius contracts readily; vastus internus also contracts readily, but not so well as the vastus externus. Right thigh (posterior half)—weak current: Semi-tendinosus and adductors contract very feebly; semi-membranosus and biceps contract moderately. Left thigh (posterior half)—weak current: Semi-tendinosus and adductors contract fairly well; semi-membranosus and biceps only weakly. Right leg (anterior half)—weak current: Extensors and peronei contract readily. Left leg (anterior half)—weak current: Tibialis anticus contracts only slightly; peronei and extensors less than right leg. Right leg (posterior half)—weak current: Flexors contract moderately well. Left leg (posterior half)—weak current: Flexors contract feebly. There is slight anæsthesia behind the left external malleolus and in the sole of the left foot. Tactile sensation delayed in the outer side of the middle and lower thirds of the left thigh. Pressure on the sole of this foot causes pain. There is hyperæsthesia of the three outer toes of the left foot. Along the front and inner surface of both tibiæ near the anterior edge there are hairless patches. These are about an inch and a half in length by a quarter of an inch wide. Previous to the disappearance of the hair some redness had appeared.

24th.—Temperature last night rose to 102·2°, while the pain and tenderness in the back returned. There was also pain of a shooting character in the left leg and foot. There has never been any girdle pain. Temperature this morning 98·6°.

Sept. 8th.—Has been quite free from pain the last few days. With a little assistance he is now able to stand, and to walk a few yards. Has had a poroplastic felt jacket made to fit the back. This gives him great support. Hyperæsthetic spot in left foot still present. Complains of a feeling of constriction in the left leg on flexing the foot.

16th.—A relapse last night. Temperature 103°. Had distinct rigors. Return of the shooting pains in the back and left leg. This, which was the last febrile attack, lasted two days. From this time the patient began to make a more decided improvement, which has steadily and uninterruptedly continued up to the present time. On Oct. 15th he left the infirmary, after a stay of five months, and went to the convalescent hospital at Cheadle. Since his discharge he has made periodical visits to the infirmary.

Remarks by Mr. JONES.—In this case the spinal displacement was produced by extreme flexion of the spine, the result of a heavy weight falling upon the upper part of the column. The effect of this would be to rupture the ligaments between the spinous processes and the neural arches, and so allow incomplete separation of one vertebra from another. The ease with which replacement took place was certainly remarkable, and the sound which accompanied it was so distinct as to be audible to all the bystanders. The alkalinity of the urine became apparent on the third day, and it was thirty-five days before it regained its acidity. The expelling power of the bladder is still wanting; even now, eight months after the accident, he is compelled to employ a catheter. It is difficult to offer a reasonable explanation of the recurrent febrile attacks; they may possibly have been occasioned by a slight transient inflammation of the spinal meninges at the seat of injury. The trophic changes observed were not numerous. The bullæ began to appear at the end of forty-eight hours, and it is quite possible the error we committed in applying the plaster to the legs for the purpose of extension may have been instrumental in their production. The same may be said of the patches devoid of hair. They corresponded in position and extent to the redness produced by the pressure of the bandage. When seen a few days ago, the patient had regained his strength to such a degree that he could walk with comfort, without support of any kind. The bladder condition remained the same, so did the anæsthetic spot on the sole of the left foot. There is some thickening in the upper lumbar region, and the spines of the first and second lumbar vertebræ are closer together than they should be normally.

CASE 2. *Dislocation with Fracture of the Fifth and Sixth Cervical Vertebræ; Reduction; Death; Necropsy; Remarks.*—Thomas W——, aged twenty-seven, was admitted on June 7th, 1884. The patient was wrestling when he fell, striking his back against a large stone, while the head was jerked violently backwards. At the same instant he experienced great pain in the back, and discovered his inability to move any of his limbs. When first seen he was exceedingly pale and cold; pulse very slow (31 per minute) and compressible; pupils equal and rather dilated; breathing entirely diaphragmatic and very laboured; the limbs were quite flaccid and remained in any position they were placed; no response to stimuli applied to either arms or legs. On examining the cervical part of the spine, a very marked depression involving the fifth and sixth vertebræ, with swelling of the soft parts in the vicinity, was found. He was at once placed on a water-bed, with hot bottles near the feet to hasten reaction. By the next morning the patient had rallied, and he now could give a rational and connected account of the accident. His face was flushed. Temperature 100°, pulse full and rather bounding. No changes in the state of the breathing, nor in the condition of the limbs. He complained very much of the pain in the lower and back part of the neck, which was increased by any movement and pressure. Sensation quite normal in the head and neck; entirely absent in the lower limbs and in the trunk as high as the third intercostal space on each side. There is also anæsthesia of the upper extremities as high as the middle of the deltoid; above the anæsthesia there is an ill-defined zone of hyperæsthesia. There is complete loss of motion in all four extremities. Retention of urine.

Mr. Wright saw the case with Mr. Jones, and it was decided that an attempt at reduction would be justifiable.

The patient having been gently rolled over to his left side Mr. Jones grasped the occiput with the right hand while the left pressed against the chin. He then slowly and deliberately flexed the neck, and while doing so the deformity disappeared with a decided crepitant sensation. The head was then placed on a pillow, with a sand-bag on each side to steady it. As the result of the reduction, it was observed that the right arm had regained the power of motion; no change in the sensation was produced. These manipulations were carried out about 11 A.M. Late in the afternoon the breathing became more embarrassed, and was accompanied by very evident distress. He complained of great thirst, and the temperature inclined slightly upwards. The dyspnœa increased, the lips and face became livid, unconsciousness followed, and the patient died in the evening.

Post-mortem examination.—There were the usual signs of death from asphyxia. Some extravasation of blood among the muscles of the back. On opening the spinal canal there was found some extravasated blood around the cord in the cervical region and some in the lower dorsal. The cord opposite the lower cervical vertebræ was much bruised, and blood had been freely extravasated into its substance. There was fracture through the body of the fifth cervical vertebra, with free destruction of the capsular ligament between the fourth and fifth. No displacement.

Remarks by MR. JONES.—The injury to the cervical spine was no doubt produced by over-extension of the neck, which caused a forward displacement of some of the vertebra, in all probability the fifth and sixth. From the first the case appeared to be a very hopeless one; still, having seen the good effect of extension in another example of spinal dislocation, we were sanguine enough to believe that some benefit would result from the proceeding adopted. Had the injury to the cord been less extensive and its destruction less complete, the replacement of the bones might have been attended by a very different termination. It is always a very anxious question to decide in cases of spinal injury whether the surgeon is justified in carrying out any active treatment. Judging from what we saw in these cases, it would appear that when the injury has been produced by over-extension or a too free flexion of the spine, then interference is right and proper and may be attended by the best possible result. It might be suggested that in the attempt to reduce a displaced vertebra, we may very easily inflict additional injury on the cord. To avoid this we must always take care that the treatment is conducted with great discretion and gentleness, for rough handling can only end in disaster.

ROYAL UNITED HOSPITAL, BATH.

A NEEDLE IN THE BLADDER SIMULATING STONE; REMOVAL BY LITHOTOMY; RECOVERY.

(Under the care of Mr. HENRY W. FREEMAN, F.R.C.S.I.)

A LITTLE boy, under four years of age, was brought to the out-patient department of the hospital by his mother on Nov. 26th, 1884, suffering from bladder irritation, with symptoms of stone. The history elicited by Mr. Roberts, the house-surgeon, ran as follows: Difficult micturition, with screaming; pain commenced in August, 1883, accompanied with blood, sometimes more, sometimes less; and this condition of things continued for a year, when the bleeding ceased, and micturition, although painful, became bearable. The child had been sounded frequently for stone during this period, but nothing had been discovered, and as the symptoms were thought by the medical man in attendance to be due to phimosis, the boy was circumcised twice, but no relief in any way resulted.

On admission into the hospital Mr. Freeman, in conjunction with his colleague, Mr. Ransford, explored the bladder, under chloroform, and on passing a sound into the bladder a grating noise was heard when the instrument was held horizontally and in contact with the posterior portion of the fundus of the bladder, as if a phosphatic calculus were embedded in its coats; but when held vertically, and the curved portion rested on the most inferior portion of the organ, a distinct chink was heard, as if a smooth stone were struck. This, however, was very limited in extent, and it was noticed that the point of the sound could not be got round the foreign body to determine its size or shape. It was fixed. Digital examination of the rectum revealed nothing. The general consensus of opinion was, that a phosphatic calculus had become embedded in the walls of the bladder, and accordingly lateral lithotomy was performed by Mr Freeman on Dec. 6th. On opening the bladder, a sharp body was felt sticking in the anterior portion of the prostate, lying obliquely over the trigone, and resting against the posterior surface of the fundus, and encrusted with calcareous matter. A long pair of flat-pointed dressing forceps were introduced, and, after a little manœuvring, a small-sized "darning needle," measuring 1⅛ in. in length, and covered for more than an inch with phosphatic deposit, was extracted. The deposit was ⅛ in. in thickness, and included the sharp point, which was as thickly covered as the rest of the shaft; but the eye—blunt end—of the needle, for three-eighths of an inch, was smooth and free of deposit. There was no hæmorrhage. The child passed his urine by the urethra on the thirteenth day after operating, and, at the end of a fortnight, the urine, becoming excessively ammoniacal—due, as pointed out by Dr. Ray Lankester, to the presence of bacteria—and with a temperature of 102°, he was put on quinine, which speedily settled the thing in forty-eight hours; and, besides stating that the external wound was healed at the end of the third week, and that he contracted measles at the end of the fourth week, there is little to record, as he left the hospital well before the sixth week had expired.

Remarks by MR. FREEMAN.—Cases have been recorded where lithotomy has been done in boys where portions of slate pencil have found their way into the bladder by the urethra, but a needle in the bladder of a child, by whatever route it may have got there, followed by lithotomy for its removal, is of rare occurrence. The position of the needle in this small bladder seemed to me as if that portion sticking in the prostate dammed up in a measure the internal meatus, and the little constant whirlpools of urine around this portion of about half an inch explains why it was bright and gave the metallic ring when struck with the sound. We knew nothing of the needle history until after the operation had taken place, but the mother was positive that a "darning needle" such as we extracted had been swallowed by this child before her own eyes on Whit Sunday, May 13th, 1883. The needle, according to the mother's statement, was in the child's body about eighteen months, and the question arises how it found its way into the bladder. My first impression was that the needle had been thrust along the urethra by some precocious nurse girl, but the mother asserts that the child had never been out of her hands. Then came the history of its being swallowed, and if this was the identical needle, how did it get into such a receptacle as the bladder? Did it pass into the bladder by the rectum or by the small intestine; or, bearing in mind the anatomical relations of the ascending and descending colon to the kidneys, did it pass through the bowel into the pelvis of the kidney and thence by ureter into the bladder?

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

New Growths in Intestines.—Spondylolisthesis and other results of Pressure on the Spinal Column.—Lung Disease in Wild Animals.—Sudden Death from Impaction of Trachea by a Bronchial Gland.—Malignant Growth in the Forearm of an Infant.—Renal Cancer associated with Calculi.

AN ordinary meeting of this Society was held on Tuesday last, Dr. J. S. Bristowe, F.R.S., President, in the chair. Mr. Bland Sutton's communication on Comparative Pathology was warmly applauded.

Dr. NORMAN MOORE read a paper on Cases of New Growth in the Alimentary Canal. The first case was one of carcinoma of the cæcum spreading to the duodenum by direct contact in a woman aged forty-four, who was under Dr. Moore's care in St. Bartholomew's Hospital. There was ulceration over an extent of four inches in the cæcum, and the ileo-cæcal valve was invaded. A deep opening led from the inner part of the colon to the sixth inch of the duodenum by way of firm adhesions; this part of the duodenum was also infiltrated. The vermiform appendix was adherent to the cæcum, and also infiltrated. The subjacent organs were not affected. Only one small gland near the front of the cæcum was diseased. The patient had been ill since January, 1883,

and wasting from October till April, 1884. Pain in the right side, vomiting, diarrhœa, anæmia, and a slightly movable tumour lying between the ribs and iliac crest were the symptoms and signs noted. In two months the tumour became a little larger and rather less movable. The only constant symptom was general diarrhœa. There was no melæna. She died suddenly in August, and an adherent clot was found in each pulmonary artery. The second case was one of carcinoma of the descending colon spreading in direct continuity to the stomach of a woman aged forty-six, who was under the care of Dr. Gee. The new growth affected the middle part of the descending colon, and it was ulcerated at its base. The stomach was affected for about three inches, and there was a very large ulcerated hole in the stomach leading directly into the descending colon. The cancer was adherent to the parietes, and the fascia had begun to be penetrated. There were no secondary deposits. There had been pain in the left lumbar region since August, 1884, and the swelling appeared soon after, and continued to increase till death in Feb. 1885. Anæmia, slight melæna, and diarrhœa, and occasional sickness were the signs noted. Both these cases were remarkable as carcinoma spreading by direct continuity only, and both illustrated the difficulty of exact diagnosis in such cases. The age of the patient and the characters of the tumour were similar in each case, as were also the slight rise in temperature and the intense anæmia. Spread by direct continuity was only present in six instances out of twenty-four post-mortem examinations of cancer of the intestines made from cases in the medical wards of St. Bartholomew's Hospital during the past three years. In one case the new growth had opened from the stomach to the transverse colon. The third specimen was one of sarcoma of the descending colon taken from a man aged twenty-five; the symptoms were those of obstruction. There was a ragged new growth which included the whole intestinal wall of the upper part of the descending colon. It was a round-celled sarcoma of loose structure, and seemed to have grown in from the peritoneum. There were no secondary deposits. The illness lasted but a few weeks. The fourth specimen was one of sarcoma of the descending colon and ileum, spreading by direct continuity, taken from a man aged forty years. The new growth began about the middle of the colon, and there protruded as a pink and white mass without ulceration. The peritoneum and rectus abdominis were penetrated and a sinus opened externally. The ileum was adherent to, and penetrated by, the new growth. No glands and no remote organs were affected. The patient was under observation for one year. The sinus was due to surgical treatment. Acute peritonitis closed the scene. These two cases of sarcoma of the intestine resembled one another in the fact that both terminated in peritonitis, due to the rupture of the loosely-formed growth. In their continuous infiltration their natural history was similar to that of the two cases of carcinoma. These were the only two cases of sarcoma out of twenty-six cases of new growth of the intestines recently examined by Dr. Moore. These specimens show that a new growth may spread by continuity only, irrespective of its pathological nature. They illustrated the difficulty of determining in what direction and over what area any new growth may spread. Dr. BRISTOWE asked what Dr. Moore meant by spreading in direct continuity. (To this the reply was a spread of the growth in a *right* line.) Dr. Bristowe then said that sarcomatous tumours were particularly rare. He had seen many cases more or less resembling those described by Dr. Moore. A male and a female case of malignant disease of the cæcum were referred to. There were no secondary growths; the spread was by continuity. After some pain a movable tumour appeared, which, in the case of the woman, might have been mistaken for a kidney. There was no disturbance of the bowels. Emaciation was progressive. The tumour was punctured, but nothing more than gas and fæcal matter escaped, and a superficial abscess formed. The case of the man was almost similar. A puncture was also made here, with the result of the formation of a superficial abscess. In other cases the colon and the stomach communicated directly as the result of the ulcerative disease.

Mr. ARBUTHNOT LANE described some of the changes produced by Pressure in the Spinal Column. He referred to a paper on spinal deformity produced in labourers by carrying heavy loads (Medico-Chirurgical Transactions, 1884), and showed that in most of these cases the weight was supported in great part by the much enlarged and thickened lumbar spinous processes, which articulated with one another by broad surfaces, surrounded by a capsule. The weight was supported also by the articular processes, which increased in size, and articulated by flattened extremities, with deep depressions in the opposing laminæ, especially in the case of the sacrum and last lumbar vertebra. As there was little tendency to forward displacement, the articular surfaces were simply flattened, and retained their inward and outward direction. In many cases osteophytic growth took place from the adjoining posterior margins of the sacrum and lumbar vertebræ. This might touch the enlarged sacral articular process, and sometimes almost obliterate the intervertebral foramen, probably causing irritation or destruction of the fifth lumbar nerve. In other cases, especially in those that are produced by carrying weights on the back, there was a marked tendency to forward displacement of the lower lumbar vertebræ, the fifth more particularly. In early cases this produced an alteration in the direction of the articular processes from a lateral direction to one looking forwards and backwards. The reason of this was obvious. The articulation between the body of the fifth lumbar vertebra and sacrum was rendered loose, so that by pressure forwards displacement could be produced. In more advanced cases, besides increased changes in the articular processes, permanent forward displacement of the fifth lumbar vertebra or spondylolisthesis ensued. In some cases there was an articular cavity between the two bones, while in others their opposing surfaces were irregular and were connected by dense ligamentous tissue. In these, by the approximation of the laminæ of the fifth lumbar and the posterior margin of the sacral facet, the intervertebral foramina were encroached on or obliterated, and the fifth nerve more or less destroyed. He showed two well-marked cases of spondylolisthesis produced in this way. One, in which there was no synovial space in the lowest fibro-cartilage, presented synostosis of both sacro-iliac articulations, distinctly caused by pressure. He had shown a similar specimen last year. He referred to two other instances of spondylolisthesis, which he had described in the last volume of the Transactions. In the dissecting-room this condition was not infrequently met with in the early stage. Dr. Neugebauer collected descriptions of seventeen specimens from various Continental museums, one of which, "Bassin de Praqua," closely resembled three of those that he (Mr. Lane) had described. This condition was certainly not so rare as Dr. Neugebauer supposed.—Mr. SHATTOCK said that Mr. Lane's arguments proved that there were other causes than that given by Neugebauer for spondylolisthesis. Neugebauer visited all the museums, and found only one specimen, which had come from a patient under the care of Dr. Hewitt. Neugebauer believed that there was a congenital defect of union between the arch of the fifth lumbar vertebra and its body. Mr. Lane's specimens showed that there was a want of continuity between the lamina of the fifth lumbar vertebra and its body; spondylolisthesis might be due to bending of the bones which were softened from senile atrophy.

Mr. J. BLAND SUTTON made an elaborate communication on Pulmonary Diseases in Wild Animals, in which he gave a general account of the zoological distribution of certain forms of lung disease among wild animals dying in the Zoological Society's Gardens during the past three or four years. The opinion held by the medical profession and the world at large that wild animals in captivity die from pulmonary tuberculosis lacked foundation, and was certainly erroneous. The conclusions drawn were founded on the following series of cases. From October, 1881, to December 31st, 1884, the total number of deaths was 2779, made up of 583 mammals, 1408 birds, and 788 reptiles. Of the 583 mammals there were 303 quadrumana, including 7 anthropomorphous apes. Of these mammals five died from pulmonary tuberculosis—namely, a tree-porcupine, eyre, kinkajou, lagotis, and an agouti; only one case of general tuberculosis was seen, and that was in a coatimondi. It was remarkable that all these tuberculous animals came from South America and the tropical portions of North America, a region named by zoologists the "neo-tropical region." It differs from all the great zoological divisions of the earth's surface by the almost unequalled extent and luxuriance of its forests, its delightful climate, and the richness and variety of its animal life. It was also the home of the guinea-pig. Pneumonic phthisis had been seen in twelve cases, of which five

were monkeys and the rest carnivora. Even if these cases, by the utmost elasticity of the term "tubercle," be included, tuberculosis was a very infrequent cause of death in wild animals. The lungs in many of the cases of tubercle were examined by Dr. Heneage Gibbes for bacilli, and he found them present, not in thousands merely, but in millions. Dr. Gibbes has worked out some very important facts in connexion with these micro-organisms, but this part of the research was left entirely in his hands, and the results will be published in a separate paper. Since mammals in confinement did not die from tuberculosis, it became necessary to give an account of their fatal diseases. It might be broadly stated that each group of animals had certain forms of chest affections common to the group. Thus primates, excluding man, suffered from bronchitis, atelectasis, and lobular pneumonia. Carnivora were exceedingly liable to double pleurisies, lobar pneumonia, and bronchitis; whilst ruminantia had the peculiar disease known as "Perlsucht" (the so-called bovine tuberculosis), bronchitis, and "worm" bronchitis. It will be seen that bronchitis, zoologically speaking, was widely diffused, and this was to be accounted for by the vicissitudes of the English climate, in contrast to the tropical climate, to which many of these animals were accustomed. Although birds had been excluded from this report, so far as tuberculosis was concerned, yet there was one pathological condition peculiar to them which was of great interest. It was well known that in birds the bronchia were in communication with a series of membranous cavities known as air sacs. It happened, with especial frequency in waterfowl, that the lining membrane of these sacs inflamed, giving rise to exudation. This inflammatory matter coagulated, and often formed a covering half an inch in thickness, which formed an excellent nidus wherein the mould penicillium might luxuriate and form a thin layer throughout the entire series of these air chambers. Hunter, Owen, Müller, Robin, and others had noted the presence of mould in the air sacs of birds, but they all seemed to have overlooked the exudation. The interest of this condition lay in the fact that this mould did not confine itself to the air sacs, but even permeated the intercapillary air spaces of the bird's lung, which corresponded to the alveoli of the mammalian lung. In view of these facts, was it a matter for wonder that, in the human lung, vegetable organisms, a fraction of the size of the spores of penicillium, requiring similar conditions for existence, occurred, such as were recognised under the name of bacilli. It was impossible to narrate all the details of the numerous cases of pulmonary affections which were to be observed. The "field of work" such an inquiry opened up to those who had the leisure and opportunity was immense. —Dr. CARRINGTON remarked on the manner in which the tabulation of the kinds of diseases was made, as though the diseases perfectly differentiated; he would like to know more of the clinical history of these diseases.—Dr. BRISTOWE asked whether bacilli were found in cases of pneumonic phthisis and lobular pneumonia, to which Mr. SUTTON replied that the bacilli were not present in merely pneumonic cases.—Dr. CHURCH asked what proportion of the 303 quadrumana were subject to lung disease; the reply to this was 30 per cent.—Dr. COUPLAND inquired whether the bovine tuberculosis was identical with the tuberculosis of other animals.—Mr. SHATTOCK said that the bacillus was a vegetable; we might study the distribution of vegetables in relation to disease, just as Mr. Sutton had studied the distribution of animals in relation to disease.—Dr. PERCY KIDD did not understand whether the bacilli were present or not in pneumonic phthisis.—Dr. GOODHART asked for more information on "worm" bronchitis.—Mr. BUTLIN hoped that there would be more arrangement of the statistics when they were published.—Mr. SUTTON replied that he considered bovine tuberculosis to be different from human tuberculosis. Dr. Klein had shown that morphologically in the distribution of the lesions the bovine tuberculosis was different from that of man. With regard to "worm" bronchitis, this was a recognised affection of animals which was prevalent in young calves in wet weather, and had obtained the name of "hoose" from the curious cough. It was due to an immature worm which gets into the trachea and penetrates as far as the alveoli of the lung. The specimens of pneumonic phthisis contained more bacilli than those labelled simply tuberculosis.

Dr. PERCY KIDD showed a specimen of Caseous Gland impacted in the trachea and causing sudden death. The specimen came from the body of a boy aged seven. He was observed to have a croupy cough and somewhat stridulous breathing during life. No physical examination had been made. One night, after running about in the daytime and having complained of no urgent symptom, he suddenly awoke, screaming, coughing, and struggling for breath. He died in about ten minutes. At the autopsy the mediastinal glands were all enlarged and caseous; the enlargement was most marked in those glands lying in front of the trachea. The lower end of the trachea was blocked up by an oval partially softened caseous gland, which had been extruded through an ulcerated opening in the anterior wall of the trachea just above the origin of the left bronchus. The perforation led into an encapsulated space in front of the trachea, which contained caseous débris and traces of gland tissue. The lungs contained a few miliary tubercles in the upper lobes, but were otherwise healthy. The heart was firmly contracted and practically empty; it was quite healthy. All the other viscera were healthy. It was remarkable that, although the child evidently died of asphyxia, there was no distension of the right side of the heart after death.—Dr. GOODHART had seen a precisely similar case, and had published it with other cases of mediastinal gland disease. The child was younger. He thought that he had seen another case, but an autopsy was not made. In both cases there was antecedent bronchitis.

Mr. LOCKWOOD showed the specimen of a Malignant Tumour of the Forearm, taken from a child ten months old, which grew rapidly, and the child died from hæmorrhage three days after rupture of the new growth. The tumour appeared when the child was six months old. There was no enlargement of the lymphatic glands, liver, or spleen. The tumour seemed to grow from the interior of the radius; it was composed of embryonic tissue of the round-celled variety of sarcoma; no myeloid cells were seen. Congenital sarcomata of a similar nature had been described by Mr. Timothy Holmes as occurring in the orbits and head, but none had been put on record in this situation at so early an age.

Mr. BILTON POLLARD showed a specimen of Carcinoma and Dilatation of the Kidney, from which he had removed a large number of calculi during life. The patient was a man aged forty, who had had symptoms of renal colic for six months and had lost flesh. When first seen there was a tumour in the left lumbar region, in one part of which fluctuation could be detected, and the urine had an acid reaction, contained pus, but no blood. The kidney was sounded from the loin, but no stone was detected; nephrotomy was, however, performed, and forty-five calculi removed, together with a quantity of purulent urine. Much relief followed the operation, but the general condition of the patient did not improve, and the renal tumour did not shrink, as would have been expected if it had been merely dilated. Malignant disease was therefore suspected, and all idea of nephrectomy abandoned. The patient died of exhaustion two months after the operation. The left kidney was enlarged, due to cancerous infiltration of it and to dilatation of its cortical substance into numerous cystic cavities. In these cysts numerous calculi were found. The specimen was shown partly on account of the rarity of carcinoma of the kidney, and partly on account of its bearing on the etiology; the calculi appeared to be the primary pathological product, and the carcinoma a secondary one, probably resulting from irritation. The frequent absence of profuse hæmaturia in new growths in the kidney was insisted upon, and attention was drawn to the failure of an attempt to feel the calculi with a needle introduced from the loin, notwithstanding the great number of the calculi. The wide implication of the lymphatic glands and the extension of the primary growth beyond the kidney showed that any attempt to remove the entire diseased structures would have been futile and unwarranted.—The PRESIDENT said that the question as to whether irritation of the calculi could set up cancer of the kidney was important.—Dr. HADDEN had made necropsies of three or four cases of malignant disease of the gall-bladder, in which calculi were present and appeared to have induced the disease.—Dr. GOODHART said that there seemed to be but little doubt that cancer of the liver could be caused by gall-stones. In the Pathological Transactions, cases of this sort had been recorded, and also one of cancer of the bladder by Dr. Fagge, where the irritation of a stone seemed to be causative. Frequent catheterism was also alleged as a cause of cancer of the bladder.—The PRESIDENT said that it was well known that renal and biliary calculi were associated with cancerous disease of the viscera.—Dr.

NORMAN MOORE thought there must be some other factor in the production of the disease. There was chronic inflammation of the bile passages and neighbouring intestines, but nothing like cancer, in a chronic case of gall-stones which he had observed.—Dr. LONGHURST made some remarks on the relation of direct irritation to cancer of the lip and elsewhere.—The PRESIDENT said that the lining membrane of the kidney still remained entire; the cancer appeared to infiltrate the whole organ; there was no prolonged history of renal colic, and it was uncertain what the relation of the association was.—Mr. BUTLIN said that there was a difference between the direct irritation causing cancer of the lip and tongue and that of a calculus acting on the tissue of the liver or kidney; for, in the latter case, the seat of the irritation was at some distance from the point where the cancer first appeared.—Mr. BILTON POLLARD, in reply, said that the cancer apparently commenced at that part of the kidney from which the calculi had been removed during life. It seemed certain that the calculi preceded the cancer; probably the tumour was almost solely pyonephrotic until the time of the operation.

The following card specimens were shown:—Dr. Gulliver: Syphilitic Ulceration, with Cicatricial Constriction of the Trachea. Dr. S. West: Specimens of Mediastinal Tumours. Mr. Clutton: Large Vesico-vaginal Calculi. Mr. Sheild: Blood-clot from the Surface of the Brain. Mr. D'Arcy Power: Typical Adenoma of Breast. Dr. Hale White showed a recent Specimen of Suppurating Hydatid Cyst about the Liver, and also a Hydatid Cyst in Process of Healing, which opened into the duodenum, as well as externally through the abdominal wall.

CLINICAL SOCIETY OF LONDON.

President's Address.—Myxœdema.—Sudden Death in Phlegmonous Pharyngitis.

AN ordinary meeting of this Society was held on Feb. 13th, Mr. Thomas Bryant, F.R.C.S., President, in the chair. The President, on taking the chair for the first time, read an inaugural address, of which the following is a brief abstract:—He said that the Society had already done good work, but it was allowable to hope that that to be achieved in the future may be still better. He thought that our ideas were so constantly nothing more than the assimilation of the thoughts and observations of other men, that it was almost impossible to be original. The next point discussed was the want of care in the use of terms. "Strumous" disease was a term the meaning of which was probably very different, according to the beliefs of the individual. It would be interesting to have in writing the definitions of these phrases from the individual members of the Society. Then, with regard to the phrase "antiseptic precautions," what did it mean? To some, no doubt, it implied the "spray and gauze" system; to others it meant some sort of antiseptic irrigation, whilst to yet others it signified the use of some antiseptic either as a dry or moist dressing. He considered, further, that sufficient discrimination was not made between cases of intestinal strangulation and those of intestinal obstruction; the two conditions were widely different from one another. Again, is it not most important that we should have clear views on such general and elementary subjects as repair and inflammation? Experience led him, as an examiner of students, to believe that over this subject there is considerable confusion. In the treatment of a wound is it not the surgeon's chief object to prevent inflammation? When a granulating wound becomes the seat of inflammation the reparative process at once ceases, and what had been a granulating soon becomes an ulcerating surface. Is it not incumbent on all teachers to enunciate that repair and inflammation are not only not identical, but that they are incompatible? The one is a formative, the other a destructive, process. He also drew attention to a few practical points, such as the application of two ligatures to arteries in their continuity with division of the vessel between the ligatures; this was the practice of the last century; he did not intend to criticise this practice, for he looked on it with favour. It would be interesting if full particulars of the results of this revived method could be obtained during the present session. Again, he asked whether there was any truth in the accusation, made in recent times, that the great successes which surgeons have achieved in surgical operations had led them to undertake operative measures which might with some justice be looked upon as speculative, if not rash. Had our successes engendered an over-estimation of our own powers and led us to attempt to perform operations which past experience has not supported, and which seemed to be less founded on scientific probabilites of success than on the sanguine hopes of their performers? Are the operations upon the pylorus or stomach, for cancer, to be placed in this category? Are there other operations which should be so classed? We should avoid even the semblance of an experimental operation. He next remarked upon the kind aid which the surgeons received from the physicians in respect of such surgical work as the diagnosis of disease of the brain, kidney, bladder, and abdomen. And we were thus, with a clearer diagnosis, mutually helping to bring within the domain of scientific surgery large classes of disease which had hitherto been deemed to lie outside the pale of practical surgery. Might we not ask for even more help in this direction, and urge our medical *confrères* to seek surgical conference early, at least in all abdominal cases in which symptoms of intestinal strangulation exist, as well as in all cases in which intestinal obstruction is present?

A vote of thanks for the address was proposed by Dr. J. G. GLOVER, seconded by Mr. PICKERING PICK, and carried with acclamation.

Dr. W. HALE WHITE read a paper on a case of Myxœdema with a Post-mortem Examination. This case is the same as has been previously recorded in the Society's Transactions for 1882, page 98. From that year till June, 1884, the patient disappeared from observation. On June 12th, 1884, she was admitted into Guy's Hospital for ascites. There was still some evidence of myxœdema in the hands and face, but it was much less. The speech was slow. The abdomen was tapped, five gallons and five pints of fluid were drawn off; after this she had epileptiform convulsions, passed into the status epilepticus, and died. At the post-mortem examination there was found a small old hæmorrhage in the left corpus striatum, the vessels of the brain were thick, the thyroid was much atrophied, there was much pigmentation of the peritoneum from chronic peritonitis, the intestines were matted together, and there was perihepatitis. The heart, lungs, cervical glands, alimentary tract, spleen, pancreas, suprarenals, mesenteric glands, sympathetic ganglia, kidneys, bladder, genital organs, pituitary body, muscles, and toe-joints were all healthy. The liver showed proliferation of nuclei in the intercellular connective tissue and much deposit of fat in the centre of the lobules. The submaxillary gland showed slight increase of nuclei between the walls in the connective tissue, which seemed to have a sodden and swollen appearance. The thyroid body exhibited the remnants of vesicles, which contained much epithelial débris; the connective tissue was degenerate and sodden looking, although here and there was some evidence of a mild inflammatory condition. The sympathetic ganglia were healthy; the condition of the connective tissue was the same as that already described. The spinal cord and sympathetic nerve were normal, except that the connective tissue was like that in the ganglia. No other histological abnormality was discovered. This histological examination of the organs goes to show that the atrophy of the thyroid is the cause of the disease, because all the changes excepting this are probably secondary, and due to a myxœdematous affection of the tissues. That the sympathetic is not the cause of the disease is probable from the following considerations: first, in the case in which accessory thyroids were present no myxœdema followed excision of the gland, although there the sympathetic must have been pulled upon; secondly, the cells and nerve fibres in the sympathetic ganglia were quite healthy; thirdly, myxœdema has never been observed to follow the numerous physiological experiments in which the sympathetic has been excised. It is hardly likely that an organ like the thyroid, with four large arteries and six large veins, should not have some important function. No opinion as to disease of the sympathetic ought to be expressed from the mere size of the ganglia, as this varies much in the healthy body.—Mr. VICTOR HORSLEY said that with regard to the absence of such symptoms as tremors it should be remembered that they tended to disappear as the disease advanced. In a case of congested thyroid, which might also be described as a case of acute myxœdema, he had observed tremors of a marked kind. He pointed out that epilepsy was very frequent in cretins, and though the fits might be due to other causes,

yet the arrest of function of the thyroid might also explain their occurrence. With regard to the histology of the thyroid gland, there were merely collections of embryonic tissue to be seen in Dr. White's sections which might be described as an intermediate stage between the healthy thyroid and the complete destruction which obtained in a specimen of Dr. Ord's, where there was scarcely any of the embryonic tissue; the same changes were to be found in the experimental disease. As Wölfler first showed, this embryonic tissue normally exists about the capsule of the thyroid body.—Dr. DE HAVILLAND HALL said that in the presence of albuminuria it seemed natural to attribute the epileptiform attacks to uræmia.—Dr. W. B. HADDEN considered that the fits were sometimes due to the disease. In the investigation being made by the special committee on myxœdema, convulsions were found to have been present in a considerable proportion of the cases. The changes in the thyroid were allied to the alteration found in cirrhosis of liver and in chronic interstitial hepatitis. He had met with a case of myxœdema in which the history showed that a sister also suffered from exophthalmic goitre, and there might be some connexion between these diseases, both of which involved the thyroid.—Dr. SÉMON said all that had as yet been discovered confirmed the hypothesis he had advanced, that cretinism, cachexia strumipriva, and myxœdema were but one and the same disease. It was important to know what was the cause of the arrest of function of the thyroid. From a study of many cases he had come to the conclusion that the first change was one of cerebral anæmia, as manifested by such symptoms as giddiness and faintness. Reference was made to a case in which for the first period, which lasted five years, the signs of cerebral anæmia were most marked. It was possible that the cerebral anæmia led to trophic changes in the thyroid body, as well as indirectly to the other symptoms. Dr. CARRINGTON said that it would be equally difficult to explain the cause of the cerebral anæmia on Dr. Sémon's view. In cases of severe chlorosis and of pernicious anæmia the symptoms of myxœdema did not supervene.—Dr. GOODHART could not think that the sympathetic system was exonerated because we had not found any structural change in the ganglia; he considered that there was a close analogy between the causation of Addison's disease and myxœdema. The gland concerned in each disease might be destroyed by cancer, &c., without giving rise to the characteristic symptoms. It seemed clear that Addison's disease was due to lesion of the sympathetic nerves, though no structural changes were to be found microscopically. Considering these things he thought that sympathetic "worry" might still be at the root of myxœdema.—Dr. HALE WHITE said, in reply, that he could not say more of the epileptic fits, as he simply copied from the late Dr. Mahomed's report. With regard to the view that the sympathetic system was at fault, he thought it proved too much; moreover, none of the ordinary symptoms of a lesion of the sympathetic were present.

Drs. R. E. CARRINGTON and W. HALE WHITE read a conjoint paper on two cases of Phlegmonous Pharyngitis. The patients were seized with intense dyspnœa, and tracheotomy might or might not be performed. The operation, however, appears to be entirely useless, the general, and not the local, condition apparently leading to the fatal issue. The first case was that of a man aged forty-six, who was admitted into Guy's Hospital in the early morning. He had been ill for seven days, some days being in bed, on others at work. He was admitted with laryngeal stertor, but no marked dyspnœa. He was placed in a tent with the steam spray and watched, but in the course of a few hours he died quite suddenly, before the house-surgeon could be summoned. At the autopsy, all the soft tissues of the pharynx were œdematous; and on the right side, from the tonsil downwards for two inches, the mucous membrane was minutely injected and swollen with œdema; yellow spots of pus existed here and there. The same condition had spread into the tissues of the epiglottis. On the left side the œdema was serous only. There was very little narrowing of the rima glottidis. With the exception of subpleural ecchymoses, there were no other noteworthy points discovered. The second case was that of a medical man aged forty-nine, who was admitted into Guy's Hospital on November 10th, 1884. He was suffering from dyspnœa, apparently of moderate intensity, but he himself came to the hospital for the purpose of having tracheotomy performed. He walked up to the ward and was placed in a tent with a steam-spray apparatus. It was decided, after consultation with Mr. Clement Lucas, to perform tracheotomy three hours after admission. Just as he was about to be removed to the table he was seized with spasm of the glottis, and the operation had to be performed in the bed. Artificial respiration had to be resorted to, and was so far successful that he began to breathe spontaneously. He was then seized with an epileptiform convulsion, and ceased to breathe again. Electricity, subcutaneous injection of brandy, and other means were resorted to, and he again began to breathe feebly. He revived so far as to take a draught of milk. All seemed well, and arrangements were made for leaving him under supervision, when he again ceased to breathe. Efforts were maintained to bring him round for a full hour, but unfortunately were not successful.—Mr. HARRISON CRIPPS spoke of the case of a healthy girl who had had gonorrhœa, and soon after suffered from sore-throat; the next morning the left side of the face was swollen, and this swelling spread considerably down the neck, and was accompanied by dyspnœa, which was so severe that tracheotomy was decided upon; chloroform was given, and in two minutes the patient ceased to breathe. The interest of the case seemed to lie chiefly in the treatment. There was a large amount of serum thrown out, for the incision necessary for tracheotomy gave vent to so much serum that it made an obvious difference in the swelling during the half hour that artificial respiration was resorted to. Acute œdema of the neck was therefore most dangerous, and ought to be treated by free incisions into the skin, and perhaps scarification of the pharynx and laryngeal folds. From his experience of cases of dyspnœa he considered that all operations, where this symptom was urgent, should be performed without an anæsthetic.—Mr. HOWARD MARSH said that apparently these cases of phlegmonous inflammation had not attracted much attention, though Porter of Dublin had written on them in a book entitled "Diffuse Cellulitis of the Neck." Mr. Marsh had had about three cases of the kind under his care. In the first case the patient had suffered for twelve hours from obstruction in the larynx; later on swelling appeared in the parotid region and upper part on one side of the neck, and spread rapidly across the middle line, so that this "succulent œdema" was most extensive; it was accompanied by severe prostration and a low temperature. This case went on to diffuse and widespread suppuration, which spread down into the anterior mediastinum; gangrenous inflammation supervened, many incisions were made, and the laryngeal tissues scarified; a horribly offensive expectoration was present; and notwithstanding quinine and stimulants, death ensued from asthenia.—Dr. GOODHART considered that the class of cases described by Dr. Carrington ought to be separated from those referred to by the previous speakers, and which were also known as angina Ludovici. In Dr. Carrington's cases there was no marked swelling of the neck, and sudden death occurred, whilst there was no great degree of dyspnœa. The condition of the pharynx was most peculiar; it had a brawny aspect, and might be followed by suppuration in a short time; albuminuria was often present. It was difficult to say what precise relations this inflammation had to diphtheria.—A MEMBER related his own case of acute œdema of the larynx. At midday on June 23rd, 1873, he was attacked with shivering, and later found he was unable to swallow and had difficulty in breathing. Mr. Christopher Heath performed tracheotomy, and the tube was removed on the fifth day. Erysipelas or exposure to cold and wet might have caused the malady.—Dr. F. SEMON said that very dissimilar conditions had been spoken of. Some cases of phlegmonous pharyngitis seemed to be directly caused by poisonous influences, such as were at work in the causation of erysipelas and pyæmia. He related a case in which the left half of the larynx was infiltrated, and there was a temperature of 104°; the patient died, and the necropsy showed many collections of pus in the neighbourhood of the larynx, and pus was also found in the metacarpal joints of the hand.—Dr. BERNARD O'CONNOR said that poisoning from sewer gas was the cause of some of the phlegmonous inflammations.—Dr. CARRINGTON said that many of the cases referred to were essentially distinct from those he had described, for the neck was not appreciably affected, the larynx seemed perfectly healthy, and tracheotomy was useless.

Dr. SEYMOUR TAYLOR showed a living specimen of arrested Rickets in a male child aged seven years; there was most marked deformity of the trunk and limbs, with remarkable arrest of growth.

MEDICAL SOCIETY OF LONDON.

Total Amputation of the Penis.—Progressive Anæmia.—Cases of Paralysis Agitans.—Necrosis of Labyrinth.

AN ordinary meeting of this Society was held on Monday last, Mr. Arthur E. Durham, F.R.C.S., President, in the chair.

Sir WILLIAM MAC CORMAC showed a man aged sixty, in whom he had amputated the whole of the Penis for Epitheliomatous Disease. Micturition was effected per urethram, which opened behind the scrotum, by making a longitudinal slit in the divided urethra and stitching its edges to the skin in the perineum. The operation was first done by Thiersch in 1875, and in this country by Mr. Pearce Gould.

Dr. D. W. FINLAY read a paper on a case of Progressive Anæmia, which will appear in our columns next week.—Dr. COUPLAND said that Dr. Finlay's case belonged to that category to which Addison first drew attention, and which usually ran a fatal course. He believed it was impossible to draw any hard-and-fast line between cases which recover and those which prove fatal. Mention was made of a case of chlorosis in a young woman, which improved slightly under treatment by iron for three or four weeks, and then, without apparent reason, ran a steadily progressive downward course—œdema and hæmorrhages setting in. The age of Dr. Finlay's patient was the usual one at which this form of idiopathic anæmia occurs. The pathology of the disease remained most obscure.—Dr. K. FOWLER referred to a certain method of treatment recommended by Niemeyer, which consisted in giving large doses of carbonate of iron in the form of five-grain pills, made by mixing half an ounce of sulphate of iron and the same quantity of carbonate of potash.—Dr. WHITE referred to a case of anæmia in a woman aged forty-two, in which Niemeyer's treatment had signally failed; arsenic and iron were also useless.—Dr. SANSOM said in his experience the red blood-discs were much altered in size and shape, and there was much granular matter in masses distributed through the blood. As to the causation, it was possible for septic influences to play a part in some cases.—Dr. MILLER ORD thought that anæmia was a disease thoroughly wanting in unity. He considered that the alteration in the shape and size of the corpuscles was a notable feature in cases of progressive pernicious anæmia. Spectroscopic examination of the blood of pernicious anæmia showed the same bands as healthy blood. The chemistry of the blood in cases of pernicious anæmia was unknown, and the number of changes in the physical characters of the blood was very great.—Dr. FINLAY, in reply, said that he did not think the ague had anything to do with the etiology of his case. He had not noticed any conspicuous difference in the sizes of the red blood-corpuscles.

Dr. BEEVOR read a paper on cases of Paralysis Agitans without Shaking. One case without shaking was shown, and one with slight tremor only. After describing the symptoms of paralysis agitans other than tremor, the first case was given in detail. It was that of a farrier aged forty-nine, who felt weakness five years ago first in the left arm, then in the left leg, and in a year's time there was weakness first in the right leg, and next in the right arm. He has never had any tremor. At present there are: fixed attitude of the whole body, rigidity about the neck, with difficulty in looking upwards; expressionless countenance; slow, delayed movements; difficulty in rising from his seat and in walking. He has had retropulsion; the voice is monotonous and mumbling, and in speaking the lips only move; feelings of heat and restlessness are experienced. He has lost the finer movements of the hands, but the grasp is almost normal. His writing is rather wavy, especially in the up-strokes. Another patient, a carpenter sixty-two years old, had been under observation for five years. Eight years ago he began to walk with short steps, and this was followed by stiffness about the neck and general weakness. Now he has the characteristic fixed attitude, but no tremor; the face is expressionless; the speech monotonous; the movements of the hands slow, and with loss of fine movements. He rises slowly from his seat, and walks with short steps; there is propulsion and retropulsion. The writing is very bad, but not quite characteristic. He has sometimes had very slight tremor of the tongue. The next case shown was one of Dr. Gowers' patients, who had very slight tremor, involving specially the flexors and extensors of the elbows (not of the hands), particularly the left. He is forty-seven years old and a bricklayer. Five years ago, without any previous cause, he began to feel weak in the left hand, with loss of the finer movements, followed by weakness of the left leg and stiffness in both limbs. After a time slight shaking appeared in the left arm. Two years later the right arm and leg became similarly affected. A year later rigidity of the back and neck came on. He has now the typical fixed attitude, and moves his body as a whole; there is difficulty in rising from his chair, and he walks with short steps. Retropulsion has been present for the last twelve months. The face is expressionless, the tongue slightly tremulous, and the speech is quite characteristic. He also presents a symptom not before described in paralysis agitans—namely, on looking to the right or left the eyes move first, and after a slight interval the head follows. In this case the thigh muscles seem to respond more readily to direct percussion than in health. Another patient, aged seventy-three, a shoemaker, had difficulty twelve months ago in executing fine movements with the left hand, which gradually became weaker, and at the same time he began to have difficulty in moving the left leg. He has a general fixed attitude, slight stiffness of the neck, a slow gait, and difficulty in rising from a chair; stiffness and weakness of the left arm and leg; the left hand is typical of paralysis agitans with a loss of the finer movements; there is restlessness with a sense of fatigue. The knee-jerks are both well marked, the left more than the right; and there is slight left ankle clonus. About this case the diagnosis was not so certain, but the onset seemed too slow and gradual for hemiplegia, and there were no symptoms of disseminated sclerosis. It was remarked that the first patient was an undoubted case of paralysis agitans without movement, and attention was directed to the presence of slow movements and subjective weakness, yet with a normal grasp of the hands; and although the disease has existed for five years there is no tremor. The case with slight tremor was shown as an intermediate type between the well-marked cases and those without tremor. The case had been under observation for five years, but no tremor has been detected. With regard to the literature on the subject, Charcot, in his "Diseases of the Nervous System," had published two cases without movement; and a case of Dr. Gowers was also referred to. Dr. Buzzard has also published a case in his "Diseases of the Nervous System," of which the symptoms were briefly given. From the long duration (eight and five years) of two of the cases, it seemed possible that paralysis agitans might run its whole course without any tremor being present.—Dr. HADDEN asked whether there was a history of traumatism in these cases. An easy way of producing the festination or retropulsion was by using gentle pressure forwards or backwards on the head.—Dr. MILLER ORD spoke of the case of a man in which the attitude was typical, and in which retropulsion and festination were present; there were nystagmus and exaggerated knee-jerks, and on exertion well-marked tremors were developed.—Dr. BEEVOR said there was no history of injury in his cases. He mentioned the case of a woman in whom the disease supervened on fright. He had used the method referred to by Dr. Hadden.

Mr. WALTER PYE showed specimens of Necrosis of the Labyrinth. The patient from whom the sequestrum was removed was a girl aged four and a half years, and there was an abscess behind the ear. There was absolute deafness on the diseased (left) side; there was complete paralysis of the portio dura, and corneal irritation was present. The sequestrum was removed by opening the abscess and enlarging the wound, so as to allow of the withdrawal of the irregular-shaped mass of bone.

OBSTETRICAL SOCIETY OF LONDON.

THE annual general meeting of this Society was held on Wednesday, Feb. 4th, Dr. Henry Gervis, President, in the chair.

Mr. THORNTON showed Two Dermoid Cysts removed during Pregnancy.

Dr. M'KEOWN of Manchester read a paper on the Prevention of Ophthalmia Neonatorum and its Ravages. The author pointed out that the text-books and lectures on midwifery should deal fully with the etiology, progress, and treatment of ophthalmia neonatorum, and that midwives

should be taught and required to understand their duties with regard to the disease. Infective matter in the genital passage of the mother is a frequent cause—it has been stated to be the only cause; and hence attempts have been made to prevent the disease by treatment applied to the vagina before delivery, and to the child's eyes immediately after birth. It was claimed that by vaginal injections the frequency of the affection had been diminished, and by some that by treatment of the eyes the disease had been prevented. Abolition of the disease was stated to have been obtained by Credé in 499 cases by washing the eyes with pure water and then applying a 2 per cent. solution of nitrate of silver. At the Stuttgart Maternity, by Credé's plan a large reduction in the frequency had been effected (*a*) by the nitrate of silver treatment in the wards of Professors Carl and Gustav Braun, where, of more than 3000 births, only 1·93 per cent. were affected, whilst of 1887 born at the same time, but not similarly treated, 4·34 per cent. were affected; (*b*) by Professor Olshausen, who, by washing the eyes with a 1 per cent. carbolic solution, reduced the percentage from 12·5 to 6 per cent.; (*c*) in the practice of Professor Simpson, by the nitrate of silver treatment; (*d*) of 2266 births in the practice of Dr. Abegg, who washed the eyes immediately after birth with pure water, only 3 per cent. were affected; (*e*) reduction in the frequency had also been obtained by Bischoff, who, by vaginal carbolic injections and washing the eyes with salicylic lotion, reduced the percentage from 5·6 to 2·6, and also by Credé, by vaginal injections (carbolic and salicylic). These results warranted an extensive series of investigations in order to determine to what extent the occurrence of ophthalmia neonatorum might be prevented, and what methods of treatment yield the best results. These points could be settled only by those in obstetric practice. Inquiries were needed regarding, first, the influence of cleansing and disinfection of the genital passage of the mother previous to delivery. Was this a plan of treatment which might be adopted as a routine practice in every case of labour? Secondly, the influence of simple cleansing, and astringent treatment of the eyes immediately after birth. The entire treatment of the eyes should be in the hands of members of the profession, and investigations should be made in the various lying-in hospitals of the country by the resident medical officers of those institutions.—Dr. GRAILY HEWITT remarked that although our knowledge of this disease had greatly improved, the difficulty of diffusing this knowledge among those entrusted with the early management of infants remained. To this end the Obstetrical Society was able to contribute largely. Some years ago the Society drew up a most valuable code of instructions for the management of infants, which had proved most useful, and was largely sold by Messrs. Longmans at a nominal price. He suggested that a paragraph should be added to these rules containing the necessary information with regard to ophthalmia neonatorum, this paragraph being drawn up by the Council. The main object was to emphasise the danger of the disease, as well as the necessary preventive measures. Students attending cases of midwifery should also have their attention drawn to it.—Dr. CLEVELAND proposed that a copy of these rules should be sent to every Fellow with the next volume of the Transactions. This was seconded by Dr. ROPER.—Dr. WILLIAM DUNCAN said that the great majority of the cases occurred among the lower orders. He had made a rule at the Middlesex Hospital that all cases of ophthalmia neonatorum occurring in the maternity department should be sent at once to the ophthalmic surgeon. He strongly deprecated students and midwives being encouraged to treat these cases.

The PRESIDENT said he had been requested to call attention to the series of questions on puerperal pyrexia published by the Collective Investigation Committee in the *British Medical Journal* of the preceding week, and to ask the co-operation of Fellows.

Certain changes in the laws were then explained by the PRESIDENT, and adopted by the Society, as were also the various reports of the officers. The list of officers and councillors proposed by the Council was declared by the scrutineers of the ballot to have been adopted by the Society.

The PRESIDENT then delivered the annual address, which will be found in THE LANCET of Feb. 14th.

A vote of thanks to Dr. Gervis, the retiring President, was proposed by Dr. GRAILY HEWITT, seconded by Dr. PLAYFAIR, and carried unanimously. The speakers referred to the unfailing urbanity and courtesy with which Dr. Gervis had presided over the Society, which had been a matter of common remark. This was combined, when necessary, with firmness, both in the Society and in the Council. The remarks of the speakers were most cordially received.

The proceedings terminated with votes of thanks to the retiring treasurer (Dr. Potter, President elect), and the retiring Vice-Presidents and members of the Council.

CAMBRIDGE MEDICAL SOCIETY.

AT the meeting on January 2nd, Dr. P. W. Latham, president, in the chair,—

Mr. HYDE HILLS read the notes of a case of Delirium Tremens in which he had used Hyoscyamine. He was called up one morning to see a fine healthy looking man, aged thirty-four, who had been drinking a bottle of brandy a day for ten days, but had taken none for the last twenty-four hours; he had not slept for three nights and was now delirious, with the usual symptoms. Mr. Hills administered a quarter of a grain of hyoscyamine in a little brandy-and-water at 4.30 A.M.; and at 7.30, being still restless and noisy with dilated pupils, a second dose of one-sixth of a grain was given. At 1.30, as he did not sleep, one-third of a grain was administered, after which he remained quiet for about two hours. At 9.35 P.M., though still showing the effects of the drug in dilated pupils and dry tongue, he was given five-twelfths of a grain. He had a restless noisy night, and was worse than ever. His pulse was 120; he complained of thirst, and had taken no nourishment for thirty-six hours. At 5.45 A.M., or twenty-five hours after the first dose, he was given seven-twelfths of a grain; he was soon quieter, and in two hours was asleep. In the morning he was quite right, and soon recovered. The same drug was used in five other cases of delirium tremens. In three cases a quarter of a grain given at bedtime produced sleep, and was not again required. In two a quarter of a grain was given ineffectually, but one-third of a grain in the morning had the desired effect, and both recovered. In a case of mania a third of a grain produced rather alarming symptoms. Mr. Hills had no doubt of the efficacy of the drug in these cases. His practice was to give a quarter of a grain first, and, if necessary, increasingly larger doses every six hours in some alcoholic beverage. Merck's solution of the amorphous hyoscyamine was the preparation used.—Mr. CARVER had used the drug on two occasions. In one case of delirium tremens after bromide of potassium and chloral had failed, small repeated doses of hyoscyamine quieted the patient within twelve hours.

Mr. WALLIS narrated a case in which he had performed Perineal Section for Cystitis in Fractured Spine, in a man admitted into the hospital with fracture of the cervical spine, and in whom severe cystitis was rapidly bringing on a fatal result. The operation was performed in the usual manner, and a long elastic tube inserted. The result as concerned the cystitis was immediately beneficial, and the patient rapidly rallied from his dying condition and gained flesh. He died subsequently from other complications.—Mr. WHERRY quite concurred in the beneficial results obtained by perineal section in this case, and drew attention to the trouble caused by the accumulation of phosphatic deposits round the tube.

Mr. WALLIS related two cases in which he had used Cocaine with satisfactory results: a case of foreign body in the cornea, and before the treatment of corneal ulcer with nitrate of silver.

MIDLAND MEDICAL SOCIETY.

AN ordinary meeting of this Society was held on Jan. 21st, Mr. T. H. Bartleet, F.R.C.S., President, in the chair.

Mr. BENNETT MAY showed a girl whose Common Carotid Artery he had Ligatured for Hæmorrhage from the External Auditory Meatus, undoubtedly due to erosion of the internal carotid artery, occurring during the fourth week of an attack of scarlatina. The case had been previously reported to the Society in an incomplete form. Since then certain nervous symptoms which attended the application of the ligature had been investigated by Dr. Suckling, whose report was appended. The girl had thoroughly recovered, and Mr. May remarked that the case appeared to be the

only successful one of the kind recorded. Politzer stated that thirteen cases of a similar nature are to be found scattered throughout surgical literature, and that every one of them had terminated fatally.—Dr. SUCKLING read a report on the nervous symptoms in the above case.

Dr. MALINS showed a Uterus removed by Elastic Ligature.

Dr. SUCKLING showed a case of General Paralysis of the Insane. The man, aged thirty-six, had been unable to follow his employment for the past eighteen months on account of his mental disorder, which was characterised by forgetfulness and irritability when in any way interfered with. The condition of *bien-être* was well marked. There was marked tremor of the lips, tongue, and facial muscles, especially when put in action; there was also inequality of the pupils. No history of excess could be obtained.

Mr. LAWSON TAIT read a paper entitled General Summary of Conclusions from 1000 Cases of Abdominal Section. Mr. Tait first considered the question of anæsthetics, and stated that he preferred a mixture of two parts of ether and one part of chloroform given in a Clover's apparatus; this mixture he found did not cause bronchitis, and did not diminish the excretion of urine, and was less often followed by vomiting than any other anæsthetic he had used. He defined the term "abdominal section" as an operation in which the peritoneum was involved. Mr. Tait also presented an analysis of his cases, in all of which the peritoneum had been involved. The general death-rate was 9·3 per cent. Mr. Tait gave as the explanation of the much lower death-rate of his later operations the following reasons: (1) Greater experience; (2) the complete discontinuance of the clamp in ovariotomy and of the ligature in hysterectomy; (3) also the earlier stages of the diseases at which operation is now done. Mr. Tait laid great stress upon the last factor in influencing the mortality after operations.

Reviews and Notices of Books.

Clinical Lectures. By RICHARD QUAIN, F.R.C.S., F.R.S. London: Smith, Elder, and Co. 1884.—It is with much pleasure that we welcome the appearance of these clinical lectures, by an author whose name will live in his well-known plates illustrating the Anatomy of the Arteries of the Human Body. It must have been a source of entertainment and occupation to Mr. Quain to re-edit these clinical lectures, recalling as the labour must have done many of the past experiences of an active life. The volume is a costly production, illustrated by forty plates, many of which are beautifully coloured and are very valuable as pictures of rare specimens of disease. Plate XXXIII., fig. 2, is described as cholesteatoma testis; from the drawings and descriptions of this specimen we should feel almost certain that we had to do with tubercular disease of the organ in question. Plates XIV. and XV. are admirable representations of advanced rheumatoid arthritis of both hip joints, or, as we should prefer to think after reading an account of the case, of Charcot's joint disease. These two examples will serve to show some of the directions in which science has advanced since Mr. Quain took an active part in pathological work. The production of a work of these dimensions cannot have been made without considerable expenditure of time and energy, and when we remember Mr. Quain's years, we feel that he is to be cordially congratulated on the accomplishment of his task.

A Text-book of Operative Veterinary Surgery. By GEORGE FLEMING, LL.D. With numerous Illustrations. Pp. 336. London: Baillière, Tindall, and Cox. 1884.—This work does not profess to be a manual of veterinary surgery, but is intended to supply a want which has been long felt—an intelligible and practical description of the manual details of the various operations which it may be necessary to perform on animals. It does not, therefore, treat of the diagnosis of injuries, but takes up the subject when it has been decided to perform a surgical operation, and describes the manner in which, and the instruments by means of which, this may be done, with full instructions as to the measures requisite to prevent, or at least diminish to the utmost, the dangers to be apprehended from the struggles of the animal. In an introductory chapter Mr. Fleming points out forcibly the necessity for a sound knowledge of anatomy, physiology, and pathology for the successful practice of surgery. "As in clinical medicine, so in surgery, skill in *diagnosing* is an important element of success.....A great secret of success is to know when to act and when to abstain." The book is divided into two parts. The first treats of the manner of securing animals for operation; the employment of anæsthetics; and elementary operative surgery, including bandaging and dressing wounds. The second part, under the head of General Operations, includes the *operative* treatment of dislocations and fractures; the removal of tumours; cauterisation; galvano-puncture or electro-puncture; setons; injections; inoculations; operations on bloodvessels, muscles, tendons, nerves, and fasciæ; amputations; and extraction of foreign bodies from wounds. In addition to the description of the mode of operating, the book contains numerous illustrations of the instruments required, the manner of using them, and the various sutures and bandages which may be needful after an operation. As might be expected, Mr. Fleming protests against the performance of operations on animals in compliance with a mere fashion, such as "docking" or "knicking" of a horse's tail, cropping dogs' ears, or cutting their tails. "These operations, which, after all, are only fashionable mutilations of perfect animals devised by a morbidly artificial and corrupt taste, should be suppressed, if not by law, at least by the influence of the surgeon." The objection of course does not hold good when the operation is performed for the cure of disease or injury, or removal of deformity. The volume is in every way worthy of the author's reputation and high standing in his profession, and cannot fail to prove instructive; it should be in the hands of every young veterinarian, and would doubtless be found very useful for reference in the library of men of more advanced standing. We regret to add that it has the serious defect of having no table of contents and no index; both of which, with a list of the illustrations, would greatly enhance its value, and will, we trust, be added to the next edition.

A Treatise on Diseases of the Ear. By CHARLES H. BURNETT, A.M., M.D., Professor of Otology, Philadelphia. Second Edition, revised and rewritten. London: J. and A. Churchill.—We note with pleasure the appearance of a second edition of this valuable work. When it first came out—now some seven years ago—it was accepted by the profession as one of the few standard works on modern aural surgery in the English language; and in his second edition Dr. Burnett has fully maintained his reputation, for the book is replete with valuable information and suggestion. The revision has been carefully carried out, and much new matter added, more especially in the chapters on the abnormalities of the auricle, otomycosis, the treatment of chronic otorrhœa, the classification of aural polypi, and the diagnosis, etiology, and treatment of aural vertigo. The account of otomycosis is peculiarly interesting to the English otologist, as Dr. Burnett has had the opportunity of seeing a great deal of this affection, which in England is so rarely met with. The observations on the dry treatment of chronic otorrhœa by means of powdered boracic acid, &c., are most valuable, and will, no doubt, meet with very general acquiescence; but we note with some surprise that no special reference is made to the important help afforded by alcohol in the treatment of chronic otorrhœa and polypi; while, as regards the classification of aural polypi, we doubt whether Dr. Burnett's views will be generally accepted by pathologists. The author's remarks, too, on the value of removal of enlarged tonsils in the treatment of ear disease

point to a somewhat different experience from that of most surgeons. Dr. Burnett's work must be regarded as a very valuable contribution to aural surgery, not only on account of its comprehensiveness, but because it contains the results of the careful personal observation and experience of this eminent aural surgeon.

Brain; a Journal of Neurology. Part XXVIII. January, 1885. London: Macmillan and Co.—This number contains a very elaborate article (translated by Dr. de Watteville), by Professor Lichtheim of Berne, upon Aphasia, of which he distinguishes no fewer than seven types based upon clinical observation and theoretical considerations of the different paths of transmission of impressions and impulses to and from the speech centre. The essay is a most valuable contribution to a complex and difficult subject. The only other original article is one by Mr. A. Robinson, of Owens College, on the Nervous Lesions produced by Lead Poisoning, in which he describes a case observed by himself where no change at all was found either in the cord or the musculo-spiral nerve. At the same time, from a review of recorded observations, he thinks that the balance of evidence is in favour of a primary peripheral neuritis, the nerve centres being also attacked by the poison both directly and indirectly through arterial degeneration. The clinical cases are of much interest viz., one of a rare condition, having some resemblance to hystero-epilepsy, related by Dr. Hughes Bennett; one of multiple tubercular tumours involving the crus cerebri and roots of the lower cervical and first dorsal nerves, by Dr. Ross; and one of injury to the right side of the head followed by complete paralysis of the right arm (very limited laceration of the left ascending frontal convolution), by Dr. Thomson of Oldham. A "Critical Digest" of the subject of Vertigo, by Dr. George Parker, and the usual reviews of books and an extensive series of abstracts, make up a most interesting number.

The Quarterly Journal of Microscopical Science. Edited by Professors LANKESTER, THISELTON DYER, KLEIN, MOSELEY, and ADAM SEDGWICK. January, 1885. London: J. and A. Churchill.—This number contains the following memoirs:—1. J. T. Cunningham: The Significance of Kupffer's Vesicle, with remarks on other questions of Vertebrate Morphology. 2. W. H. Caldwell: Blastospore, Mesoderm, and Metameric Segmentation. 3. G. Brook: On the Origin of the Hypoblast in Pelagic Teleostean Ova. 4. H. N. Moseley: On the Presence of Eyes in the Shells of certain Chitonidæ, and on the Structure of those Organs. 5. Ray-Lankester: Archerina Boltoni, *nov. gen. et sp.*, a Chlorophyllogenous Protozoon allied to Vampyrella. 6. F. O. Bower: On the Apex of the Root in Osmunda and Todea. 7. E. v. Beneden's Researches on the Maturation and Fecundation of the Ovum. 8. W. F. R. Weldon: On the Suprarenal Bodies of Vertebrata. 9. C. B. Plowright: On the Life-History of certain British Heteræcismal Uredines (the Ranunculi accidia and Puccinia schoeleriana. 10. W. D. Halliburton: On the Occurrence of Chitin as a constituent of the Cartilages of Limulus and Sepia. There is also a correction of an error as to the morphology of Welwitschia mirabilis by F. O. Bower. There are no less than twelve plates.

The Medical Chronicle, Feb., 1885.—The original articles of this number are:—Paraldehyde, by J. Leech, M.D.; a case of Bell's Paralysis and Epilepsy of Syphilitic Origin, by James Ross, M.D.; Peptones and their Detection in Urine, by William Thomson, F.R.S. The most reliable test in Mr. Thomson's opinion is that given by Hoffmeister. The urine is first boiled with a few drops of a solution of acetate of lead; any precipitate which forms is filtered off, and to the clear filtrate one-fifth of its volume of acetic acid is added, and then a small quantity of a solution of sodium phospho-tungstate is added previously made acid with acetic acid. Any cloudiness or precipitate indicates the presence of peptone. The so-called biuret test may afterwards be applied by freeing the peptones from the phospho-tungstate precipitate.

THE PARKES MUSEUM.

AN important meeting under the presidency of the Lord Mayor was held at the Mansion House on the 13th instant, with the object of securing a larger amount of support for the Museum and of putting it on a more secure basis. The Duke of Cambridge, Earl Fortescue, Lord Mount Temple, Sir R. Rawlinson, Dr. Russell Reynolds, and Dr. Crawford, Director-General of the Medical Staff of the Army, were among those present. Letters of regret were received from many distinguished persons who were unable to attend. After the Lord Mayor had made a few remarks expressing sympathy with the object of the Museum, Capt. Douglas Galton, the secretary, read a statement giving a brief history of the institution, and explaining how, from want of room in University College, it had been transferred to its present situation in Margaret-street, where it was publicly opened by the late Duke of Albany in 1883. It is now open free part of each day. Many courses of lectures and demonstrations have been given to different classes of persons—artisans, members of building societies, the Royal Engineers, medical students, and others. There is also a valuable library, part of which was presented by the Council of the International Health Exhibition. Funds are urgently needed.

The Duke of Cambridge said that he was glad to be present, for as head of the army he felt very deeply everything that affected its welfare. Professor Parkes had done a great deal for the army during the time he was at Netley. Hygiene was more or less of a new science, and therefore it was most important that it should be studied in all its bearings, as every class in the community must necessarily be affected by the way it is carried out. The present undertaking could not be successfully continued without considerable means.

Mr. Erichsen and others having addressed the meeting, subscriptions to the amount of £1005 were promised.

THE NEW SCOTTISH CONJOINT EXAMINATIONS.

To the Editor of THE LANCET.

SIR,—Will you kindly allow me space for a few words in reply to "M.D., F.R.C.S., Edin.'s" charge of laxity against the United Scottish Corporations, whose letter is published in your issue of the 7th inst. As a student who passed the first professional in January last under the new scheme, I say that the statement that "cribbing" goes on "wholesale" is, so far as I saw, absolutely devoid of truth. Candidates do not sit where they like. On their entrance they are met by two gentlemen, who allot to each candidate the seat he shall occupy. He does not, then, sit next whom he chooses. The room is thickly carpeted, three examiners are constantly moving about, and the candidates are seated at least one yard apart. Is "cribbing" easy under these conditions? With regard to easiness of the examination *per se*, it was more severe than I expected, and the figures, as many rejections as passes, or thereabout, would not make it appear so easy as "M.D." suggests. Your correspondent seems to forget that for this diploma the candidate has three examinations, and that this one is intended for students at the end of their first year. May I state the work required for it? Well, the candidate must be well up in inorganic chemistry, and must have a good knowledge of alcohols, fats, and sugars; in anatomy he must (at least the candidates I knew did) know the greater part of "Gray," except the viscera and nervous system; and in histology he was called upon to recognise six or eight specimens under the microscope, and say what he saw and where found in the body. To the best of my knowledge the examination was fairly and impartially carried out. In conclusion, I have only to add that such a charge by one who does not publish his name against a number of gentlemen of position would be beneath notice but for the publicity your influential and widely circulated journal gives it.

I am, Sir, yours obediently,

February, 1885. T. SYDNEY DAVIS.

*** We have another letter in the same sense from another successful candidate giving his name, but we cannot afford space for both.—ED. L.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 21, 1885.

IT is said that the Government intend to reintroduce their Medical Bill, and that it is to be reintroduced it in its entirety—that is to say, in the form in which it came down from the House of Lords, and was read a second time in the House of Commons. We heartily commend the Government for this intention, if it implies a real determination to adhere to their Bill, and especially to its main provisions. We cannot, of course, after our long and painful experience of the apparent powerlessness of Parliament as now regulated, even when led by the most powerful Ministers, be sanguine that these intentions will ever be realised. The state of public affairs at the present moment makes us less sanguine still. On the other hand, this is just one of the measures that should excite no party feeling. It has been so long before the House as, by its unsettlement, to constitute a veritable opprobrium of the Legislature, the removal of which every member of Parliament has an interest in bringing about. We, however, shall be under no delusion, nor shall we be a party to bringing our readers under any delusive hopes. There is one settlement of the case against which, by anticipation, we enter our strongest protest—that is, the settlement by concession to Sir LYON PLAYFAIR. The acceptance of his resolution we shall consider a surrender on the part of the Government and of Mr. MUNDELLA, who, to do him justice, deserves credit for the pains he has taken to settle this vexed question. It will be remembered well how deeply Sir LYON PLAYFAIR misrepresented the profession last year. One of the most grievous misrepresentations was in the statement that the annual waste of the profession was 1600, whereas the Registrar of the Medical Council is, with infinite pains to ascertain all deaths, unable to obtain evidence of more than 526 deaths of registered medical men annually. Sir LYON PLAYFAIR actually conjured up to the House fears of a state of things in which the community would be inadequately supplied with medical men. The fallacy of such a suggestion is apparent from the fact that the additions to the Register amount annually to 1176, or more than twice the number of deaths; and from the obvious indications almost everywhere of superfluity of medical men, in the form often of unseemly competition for practice and undignified methods of trying to procure it. Sir LYON PLAYFAIR'S argument was cruel to the public as well as to the overfilled profession. Its meaning as regards the public was to reconcile Parliament to low standards of examination, to keep up the numbers, which, as we have shown, are only too well kept up with the present standards of examination. Mr. MUNDELLA is not an advocate for low work in Board Schools. He will act very inconsistently if he concedes low examinations in Medicine, in the efficiency of which the public have life and death interests. Sir LYON PLAYFAIR founded on this and other equally infirm grounds his amendment, which was to the effect that, instead of all entrants of the profession having to pass a Conjoint Board of Examination in certain practical subjects, those holding qualifications from certain bodies or certain combined bodies might be exempted on the condition that the Medical Council was satisfied with the final examinations of such bodies, and that in such examinations a certain number of the examiners should be appointed by the Medical Board of the division. Under the Bill, as it stands, all the medical authorities will combine to form a Board for the final examination of students, whatever their diplomas or degrees. Under Sir LYON PLAYFAIR'S plan there would be endless disputes to evade the conjoint test and a demand for extra examiners, which must add greatly to the already large expenses of examinations, and there would be endless dissatisfaction and jealousy between the bodies whose final examinations are accepted and those whose examinations are not considered satisfactory. The Government know well, at any rate Sir LYON PLAYFAIR does, that the profession has been for many years bent on the attainment of a one-portal system in which all the bodies should co-operate, and that it will be a grievous disappointment if it is lost. Sir LYON PLAYFAIR has led the House to imagine that mere conjunction of corporations is all that is wanted. He must know that this is no guarantee of efficiency while there is so much competition in the diplomatisation of medical students. Our correspondence columns have shown that under boasted conjoint arrangements great scandals still are believed to occur.

The Universities of Scotland will do well to return to their former faithfulness to the Bill of the Government. They may well begin to doubt whether they have done themselves any good by raising petty objections to a great measure on which the profession has set its mind. Sir LYON PLAYFAIR will have a chance of repentance for all the obstacles which he has thrown in the way of a settlement of this question. The Irish members may, if they like, again load the notice paper with multitudinous amendments, intelligible only on the supposition of obstruction; but there is a fine opportunity of showing that they are capable of business. We are, we repeat, under no delusive hope; but it cannot be the interest of any section of the House that respects the reputation of Parliament to allow another session to close without passing the Bill of the Government.

IN medicine there is an ever-present necessity to reconsider established beliefs and doctrines in the light of new facts, and many apparently simple conditions have been thus found to be dependent upon a number of factors which had not before been taken into the reckoning. One of the most recent instances of an attempt at such reconsideration is to be found in an essay by M. CHAUFFARD on Catarrhal Jaundice (*Revue de Méd.*, Jan. 1885), in which he advances some weighty arguments against the truth of the universally accepted doctrine of the dependence of the condition upon an extension of inflammatory changes from the gastro-duodenal membrane. His reflections are suggested by two cases of jaundice, both in habitual alcoholics, and both for some time giving rise to anxiety from the constitutional disturbance that accompanied the icterus. He points out the rarity of jaundice as a result of chronic gastric catarrh

and very pertinently remarks that instances of a spreading inflammation arising from a simple local inflammation are extremely rare. How, he asks, is the fact that attacks of jaundice occur epidemically, under some seasonal influence, to be reconciled with the notion that they are due to an inflammation spreading from the duodenum to the bile-duct? The mode of onset of such cases is often unlike that of a primary gastric catarrh; for in the two instances quoted, an exposure to cold succeeding a drinking bout was followed by a sense of weakness, muscular pains, anorexia, and vomiting; during the next few days pyrexia and a bilious diarrhœa supervened, showing that before any obstruction of the duct occurred the liver had been excited to over-activity; and it was not till the end of a week that jaundice appeared. In such a case everything points clinically to a primary irritation of the biliary gland and a secondary catarrh of its excretory ducts.

M. CHAUFFARD next turns to the renal secretion to ascertain whether an examination of the urine will afford any support to the theory he favours; and in both his cases he found that between the sixth and tenth or eleventh days the quantity of urine and of urea increased daily to a considerable degree; the former from one-half to five litres, and the urea from seven to thirty-five grammes. From this maximum point these amounts fell with oscillations to the normal. In one of the cases albuminuria was present up to the tenth day. In fact, he says the patient had then a "urinary crisis" analogous to that which accompanies the decline of an acute general disease. At first, in the invasion period, the secretion was greatly diminished, then later the occurrence of a critical diuresis denoted the entrance on convalescence. But for a long time after this the patient remained jaundiced, wasted, and enfeebled.

From such considerations it appears highly probable that in most, if not in all, cases of catarrhal jaundice, the condition is not a purely local one arising from local derangements, but a general disease running a regular cyclic course and having jaundice as one of its later symptoms. If this be so, what is its etiology? Is it to be placed among infective diseases, or is it not more likely due to an intoxication? The last-named process can be explained by reference to the ptomaines, which, formed in the digestive canal, are normally taken up by the blood and eliminated by the urine. Supposing that through derangement of normal processes they be formed in excessive amount or be eliminated ineffectually, or their noxious properties increased by the presence of alkaloids foreign to the ordinary intestinal fermentations, there would ensue a condition of auto-toxæmia, which may have but slight and transient effects, or more serious and rapidly fatal results. By such a hypothesis catarrhal jaundice would form the lowest of a series of pathogenic processes, of which malignant icterus would be the most severe and highest. It would, moreover, be supported by such considerations as result from SCHIFF'S experiments, which go to show that the liver itself exerts a destructive power upon the toxic alkaloids absorbed from the intestine into the portal blood. When, however, owing to the increase in their amount or in their virulence, from interference with the normal digestive fermentations, the liver, unduly irritated by their presence, is unable to exert its neutralising influence, the poison is diffused throughout the system. Hence the hepatic and the general symptoms, with, as a direct result of the liver irritation, the eventual supervention of biliary catarrh and jaundice. There may, of course, be predisposing conditions which render the liver less able to contend against the influx of an excess of these toxic alkaloids; and such conditions may perhaps be found in seasonal influences, in malarial cachexia, and the like.

We have kept somewhat closely to the tenour of M. CHAUFFARD'S line of argument, which certainly has the merit of being an endeavour to harmonise clinical facts with the advances made in physiology. Many must have felt that the doctrine of gastro-duodenal catarrh was unsatisfactory in view of the comparatively small proportion of cases of this common malady which are associated with icterus. And yet without further clinical observations we would hesitate to accept the new teaching; and it may be hoped that the attention drawn to the subject by M. CHAUFFARD will result in a series of clinical observations of an affection upon which little serious or profound study has hitherto been expended.

As time goes by, one after another of the impediments barring the progress of the scheme which seeks the general and unrestrained admission of women to the various branches of medical education is being removed. It is needless to point out that the goal of ambition sought by the gentler sex is not the mere acquirement of professional knowledge for its own sake, but the practical outcome of successful study in the shape of legal qualifications and licence to practise the healing art. The tide of revolution has set in very strongly, but not so strongly, it is to be hoped, but that it may yet be stemmed by the emphatic protest of a large majority of the profession, including most of its distinguished masters. The abstract doctrine of "equal rights" has been made the theme for socialistic clamour, and the ground for arguments utterly illogical. Quite recently an important institution has surrendered, unconditionally in fact, though at discretion in form. We refer to the Royal College of Surgeons in Ireland, which has, unsolicited, thrown open its doors to female candidates for their diploma. Seeing that this corporation directs the affiliated School of Surgery, it is clear that nothing is now wanting to ensure in the sister isle all that has been asked directly or indirectly of British licensing bodies. The London University has the names of several lady graduates in medicine already on its calendar, and one at least of these has taken the degree of Bachelor of Surgery. But it is at the colleges that new recruits will muster in force, for the examinations of the London University are too difficult to offer an incentive to more than a very small minority of lady aspirants.

Although the admission of women to examinations in medicine is an accomplished fact, we do not hesitate to question the wisdom of the concession. With regard to surgery the objection is infinitely stronger. A woman may be the fitting instrument to treat the ailments incidental to her sex, and in her place by the bedside of a sickly child; but we doubt the propriety and policy of committing to her care grave surgical diseases and accidents. It is not so much the quick

discernment, the prompt arrival at a conclusion, or the highly nervous and sensitive mind that are required of a surgeon, but rather the patient determination to overcome difficulty, the calmness in face of calamity, combined with strength of will; and these latter are the qualities least developed in women, who in our opinion are neither physically nor mentally constituted to solve such problems as a surgical diploma will give them a legal right to attempt.

It is on these grounds that we contemplate the recent action of the Irish College with misgiving and regret, believing as we do that neither humanity, nor the profession, nor even the parties most interested, will gain by the franchise lately bestowed. The whole subject of female medical education and qualification touches so closely on social and domestic grounds, that no step subversive of long-established usage and acknowledged utility should be taken without the fullest consideration. A stronger claim must be made before the Colleges of England and Scotland will be justified in granting what the Council of the Royal College of Surgeons of Ireland has recently conferred.

FROM time to time the obituary notices in the daily journals place on brief record the death of a public school boy. There is a passing consternation among his school companions, and some real grief in the house at which he was a boarder. But it is a wise provision in the nature of the young that sorrow should be more or less transitory. The necessary feature in our public school system that such sad events should interfere as little as possible, if at all, with the routine of school duties tends to make these sorrows of school life more ephemeral than they otherwise would be, and we think it is good that it should be so within becoming limits. This, however, does not do away with the weighty responsibility resting on the house master in the first instance, and on the governing authority of the school in the second, of carefully sifting all the evidence that can throw light on the probable or possible origin of such diseases as lead to a fatal issue in a previously healthy school-boy. There is generally more or less of mystery about such illnesses, and often an under-current of suspicion that had they been detected earlier their fatal issue might have been averted. The overpowering grief of parents and friends is too great to admit of their initiating any inquiry, which at best could afford them but little hope of comfort. The masters and governing authority naturally prefer the event to pass over with as little publicity as possible. Disease and death at a public school are equivalent to ill repute and lessened popularity, and these in due course tend to lower the number of pupils and reduce income. A full and impartial inquiry can, therefore, scarcely be looked for from within the school itself. What, then, ought to be done to give to the public school boy a full measure of protection to health and life? We hold that something in the nature of a public inquiry should be made whenever death takes place at one of these schools; not with a view of incriminating anyone, but as a measure of precaution for the future. Often much light could be thrown on such events by the medical attendant to the school; but his hands are tied and his mouth closed by the fact that his very position, and often his daily bread, are at the mercy of his employers, the masters and governors. And, further, no inquiry could take place which would not impose on the school attendant the responsibility of clearing up any suspicion of insufficient protection to the health and life of the boys under his medical charge. Yet it may be out of his power to remedy these defects. Who is responsible as guardian of the school-boy's health? On the medical attendant of a public school there is a responsibility at present insufficiently realised—a responsibility not confined to the house master or governing authority, but to the public at large. He should be no party to secrecy as to the primary cause of death in any particular case, whatever phase the secondary or immediate cause may have taken. If the primary cause can be traced to any defects in the school, or if even a suspicion exists that such cause may have had its origin in some error of discipline or too severely imposed duty when health was not at its best, outspoken candour ought not to militate against the medical attendant's interest. Nor can those called in consultation free themselves from the responsibility imposed upon them of absolute candour in such cases. To evade the duty of speaking plainly as to the primary cause of death by filling in a certificate of the secondary cause simply to avoid what is disagreeable is shirking one of the highest missions of the profession, and degrading a noble calling to worldly interests.

Annotations.

"Ne quid nimis."

THE UNIVERSITY OF LONDON.

IN compliance with a requisition, signed by members of the undermentioned committee, a special meeting of Convocation has been convened for Tuesday next, the 24th inst., to receive and consider the report of the special committee appointed on Jan. 6th, "To consider the proposals lately published by the Association for Promoting the Establishment of a Teaching University for London." The report of this committee will be presented by Mr. James Anstie, Q.C., B.A., and Dr. P. H. Pye-Smith; and the following resolutions embodied in it will be moved by Lord Justice Fry, B.A., and seconded by Sir Joseph Lister, Bart., M.B.: 1. "That, in the opinion of Convocation, the objects of the Association for Promoting a Teaching University for London would, if carried into effect by this University, add to its usefulness and importance. 2. "That Convocation now reappoints the special committee appointed on Jan. 6th, 1885, to promote the carrying into effect by this University of the objects of the said Association, with power to confer with the Senate or any committee thereof, and with the said Association, and with such other bodies as they may think fit, and with power to accept resignations, fill up vacancies, and add to their number, and also to appoint subcommittees; and that the said committee be directed to report to Convocation from time to time as occasion may require."

MEDICAL AND ENGINEERING INSPECTORS AT THE LOCAL GOVERNMENT BOARD.

UNDER the recent Treasury sanction six medical inspectors are now engaged in doing certain temporary work for the Local Government Board. Two of them, Dr. De Chaumont, F.R.S., and Dr. Davies, jun., of Bristol, have either last year or during the early part of this year

already been occupied in inspections of the ports and coast-line districts, and they will, it appears, continue to carry out this important portion of the work of cholera prevention which is being undertaken under the guidance of the Board's chief medical officer. The other four appointments appear to be of a more temporary type, for the inspectors have not yet been assigned to the inland districts which have to be inspected in connexion with the possibility of cholera importation and spread. Thus, Mr. Arnold Royle, C.B., Mr. Sweeting, of the Metropolitan Asylums Board's Western Hospital, Dr. Simpson, well known in connexion with his investigations of cholera at Damietta in 1883, and Dr. Gresswell, who holds an appointment on the staff of St. Bartholomew's Hospital, either have been or are still engaged in making certain special inspections as to outbreaks of infectious disease and other matters. But, for the moment at least, the increased medical staff has been completed. In the engineering department new inspectors have been appointed, owing to a death-vacancy and to temporary pressure consequent on the permanent staff being engaged on special work. General C. P. Carey, R.E., and Major-General A. De Courcy Scott, R.E., are the two inspectors who have been selected.

CHEMICAL LABORATORY AT CAMBRIDGE.

ALL who are acquainted with the scientific teaching department of the University of Cambridge are well aware that a new chemical laboratory is urgently needed, the present building being quite inadequate for the proper accommodation of the increased number of students, and for the carrying out of experimental researches by the professors and others engaged in such work. A syndicate to consider the matter was appointed some time since. Professor Liveing and Mr. Trotter have visited several of the new Continental laboratories, and under their supervision plans for a new laboratory, with lecture-rooms, rooms for scientific investigation, &c., have been carefully prepared by Mr. L. J. Stevenson, the architect, who has carried out their instructions in a way which appears to the syndicate to be highly satisfactory. The estimated cost is £30,000, and the difficulty is how this sum is to be raised. The prevalent idea of the wealth of the University is unfortunately a very mistaken one. Even with the additions lately derived from colleges—which, by the way, in the present state of agricultural depression can barely afford the tax laid upon them—the income of the University is scarcely equal to meet the annual demands for the maintenance of buildings and the teaching and other staffs of officers. The only way in which the funds can be raised for this and other similar much-needed purposes is by borrowing, which of course is objected to by many persons for obvious reasons. Mr. Stevenson's plan, however, is now before the senate, and was the subject of discussion in the Arts Schools on Saturday. Professor Liveing stated fully the necessities of the case, the insufficiency of the present provisions for teaching, for study, and for research, his belief that the proposed building would do no more than meet the requirements, and he thought it would well answer the purpose of the University to borrow the money required for the erection of the building. He pointed out that the site of the present chemical building is urgently required for the extension of the medical school and the proper accommodation of the increasing number of medical students. The proposal was, on the whole, not unfavourably received. Professor Humphry hoped that means would be found to overcome the financial difficulties and carry out the plan. The existing chemical laboratory was ill-fitted and quite insufficient for its purpose, not affording room for the students or opportunities for the professors, who were obliged to go elsewhere to carry on their researches. With all regard for literary, historical, and other subjects of instruction and education pursued in the University, they could not but perceive that science had now come to the front as an educational basis. The furthering it was, moreover, of the utmost importance to the national prosperity, and the instruction in it was greatly calculated to promote the interests of the students as well as to give them good mental training. Of all branches of science chemistry was perhaps the most important, the knowledge of it being essential to an apprehension of the laws governing the animate and inanimate world. He could not but hope that this discussion, revealing the financial position of the University, and the difficulty found in providing the money for this and other buildings required for the proper conduct of education, would convince the public that there are no unemployed or ill-employed accumulations of wealth in Cambridge; that all, and more than all, the funds at the disposal of the University were needed for the carrying on the proper work of the place. Unfortunately, Cambridge laboured under the double disadvantage of being poor and of being supposed to be rich. He trusted that the fact was being, or would soon be, realised, as the inner life of the University came to be better known, that in no place in the kingdom was more serious, continued, hard work being done by a large number of highly educated men with so small an amount of pecuniary remuneration than is the case in Cambridge, and moreover that the work is done well and heartily, all that was required being better buildings and better apparatus.

TANNIC ACID INJECTIONS IN CHOLERA.

DURING the recent exceptionally severe epidemic of cholera at Naples, Professor Cantani proposed combating the premonitory diarrhœa by warm tannic acid enemata. The practice was largely and successfully adopted. Dr. Vincenzo Vitone has just published, in *Il Morgagni* for last month, his results with that method of treatment at the Cholera Orphanage at S. Antonio a Tarsia. The children admitted in this institution came from the most infected parts of the city, and had lost one or both parents from cholera. Three illustrative cases may be quoted from a large number in which cholera was promptly arrested by tannic acid clysters. S. B——, aged eight, was conveyed to the Orphanage on Sept. 18th, from the house in which both his parents had died from cholera. He had enjoyed perfect health up to the time when, from no appreciable cause, he was seized with vomiting and diarrhœa. In a few hours he had ten evacuations, the last perfectly colourless. The patient complained of intense thirst and pain over the region of the stomach; the face was slightly cyanotic; temperature 36° C.; pulse scarcely perceptible. The following solution was injected per rectum: Warm water, 1000 grammes (1 gramme is equal to 15·432 grains); tannic acid, 3 grammes; gum arabic, 20 grammes; and laudanum, 12 drops. An infusion of chamomile was at the same time administered. After the lapse of an hour the boy was more wakeful, and the pulse became perceptible; the alvine discharges ceased, and in two days the patient left his bed completely cured. P. T——, aged four years, had lost her mother from cholera, and was conveyed to the Orphanage on October 10th. She was rapidly reduced by rice-coloured stools, so as to be scarcely recognisable. At 3 P.M. the temperature was 36·1° C., and the pulse almost imperceptible. The following clyster was administered: Warm water, 400 grammes; tannic acid, 2 grammes; gum arabic, 15 grammes; laudanum, 5 drops. The diarrhœa was suddenly arrested. At midnight the child was wakeful, hungry, and partook of milk. In two days she left her bed perfectly cured. A. R——, aged three, lost his mother from cholera, and was suddenly seized with vomiting and diarrhœa. The face became cyanotic, and the

extremities cold. The temperature of the body was 35·1° C.; the pulse was scarcely perceptible. A warm tannic acid clyster, according to the formula in the preceding case, was administered at once, an infusion of chamomile was given by the mouth, and the limbs were wrapped in warm woollen cloths. In the course of two hours the diarrhœa had ceased, and marked reaction set in; the temperature was 38·8° C., and the pulse 80. The following day the fever continued and the bowels acted, but the motion was well formed. The fever continued two days longer, but then subsided, leaving the child perfectly well. In adults Dr. E. Villani has injected per rectum as much as fifteen grammes of tannic acid in two litres of warm water, with invariably good result. The *modus operandi* of the treatment is attributed by Professor Cantani to the astringent power of tannic acid, and to its sterilising the comma bacilli, which need an alkaline solution for their development. Without entering into this therapeutical disquisition, the clinical results appear to afford striking evidence of the efficacy of warm tannic acid clysters in the treatment of cholera.

THE EXHAUSTION OF ENGLISH COAL.

A PAPER by Mr. Sydney Lupton, in a recent number of *Nature*, furnishes food for thought to every patriotic Englishman, for it shows by reasoning, which, at any rate, deserves the most careful consideration, that our coal-supply cannot long preserve our insular supremacy. Nearly a century has passed since the subject was first mooted by John Williams; but general attention was not aroused until 1881, when Mr. Hull, shortly followed by Professor Stanley Jevons, proved that the supply was by no means inexhaustible, the latter inquirer asserting that "rather more than a century of our present progress would exhaust our mines to the depth of 4000 feet," below which, it is believed, they would be unworkable, even if any important quantity of coal remained. A Royal Commission was appointed, which, in 1871, reported that 146,480,000,000 tons of coal remained available. This estimate is now regarded as considerably too high. Moreover, the deepest pit in England is less than 3000 feet deep, and although there is a pit in Belgium, the Lambert, that goes down to 3490 feet, such a pit could not be worked in England at anything like the present prices. Taking the figures of the Royal Commission, Mr. Lupton assumes as the present available supply 144,700 million tons. He takes one million tons as the unit, pointing out that it is equal to a cubical block 100 yards each way, or a square mile one foot thick. Dealing with this gigantic unit, Mr. Lupton proceeds to calculate from Mr. Robert Hunt's "Mineral Statistics" and other data, the past, present, and future output of coal. Following his example we will use the million-ton unit, but, for the sake of simplicity, will omit fractions. In 1854 we "won," that is, excavated, 65 units and exported 3. In 1883 we won 164 and exported 23. The total output for the last thirty years therefore increased on the average about 3 units per year, while the export during the whole period increased sevenfold. Illustrations are required to convey to the mind any idea of this enormous consumption, and we cannot do better than quote those supplied by Mr. Lupton. "It was calculated by Sir Henry Bessemer that the output of coal, 154,000,000 of tons for the single year 1881, would suffice to build fifty-five great pyramids, or to rebuild the great wall of China, and to add a quarter to its length! In 1883 the output was 163,800,000 tons, which would form a column a mile square and nearly 164 feet high; or would build a wall from London to Edinburgh 400 miles long and 45 feet 9 inches high and thick; or around the world 24,000 miles long and 5 feet 11 inches high and thick; or if the Straits of Dover are 21 miles across and 600 feet deep, would make an embankment across them 22 yards wide; while the total output for the thirty years would build a round column 9 feet 4 inches in diameter which would reach 240,000 miles high, the distance of the moon." If the output of coal continues to increase at the rate of 3,000,000 tons annually, the supply will last for 261 years; but Mr. Lupton, who has analysed the figures with care, concludes that practical exhaustion would occur in about 106 years, a period which agrees with that assigned by Professor Stanley Jevons. Space forbids us to follow the writer through his careful study of possible means for the diminution of this prodigal consumption. It is enough to say that the outlook does not seem hopeful. As to the notion of obtaining our future supply from the inexhaustible fields of America, that seems dispelled, as far as large manufactures go; by the calculation for our present supply 2100 steamers, each carrying 6000 tons, and each making thirteen trips a year, would be required, and if the price, free on board, were ten shillings a ton, "we should have annually to pay America £81,900,000, an amount not far below our present national income." The question is one which should be considered by every statesman, for those who talk so loudly about England's honour and England's place among nations, cannot be indifferent to the great decadence which would necessarily attend the exhaustion of our coal-supply. We may, indeed, ask ourselves whether, under existing conditions, the export of coal, at any rate to foreign countries, should be allowed.

A CONFERENCE ON CHOLERA.

A CONFERENCE of representatives of the principal countries of Europe will shortly be held, at the invitation of the Italian Government, in Rome, for the purpose of discussing the steps which it is advisable to take in the event of an outbreak of cholera occurring. We understand, although no definite arrangement has yet been arrived at, that England will be represented by Sir W. G. Hunter, K.C.M.G., and Dr. Thorne Thorne, of the Medical Department of the Local Government Board. Should the rumour regarding the appointment of English representatives be confirmed, we congratulate the Government upon the choice it has made, feeling sure that the opinion of the medical profession and sanitarians of this country will be fully and clearly enunciated, although we can perhaps hardly hope for many, if any, new precautions to be adopted in the event of a cholera epidemic.

WHAT WAS THE CAUSE OF DEATH?

AT an inquest held by Mr. Aspinall, the coroner for Liverpool, on January 6th, and subsequently at the assizes, the medical testimony on behalf of the Crown and the defence was singularly conflicting. It appears from the evidence that on New Year's Eve a Norwegian sailor named Johnson was engaged in a violent altercation with the three men charged with having caused his death. The question the jury had to decide was whether the deceased came to his end through the maltreatment of the prisoners or died from natural causes. Different statements were made on the two sides as to who was the aggressor, but with that we are not concerned. The case for the prosecution was that deceased had been beaten on the head with a belt and otherwise assaulted. Death followed almost immediately. The coroner's jury returned a verdict of "Wilful murder"; at the trial the accused were convicted of manslaughter. We wish to draw attention to the inconsistencies between the statements of the medical witnesses. Mr. F. Knight, house-surgeon to the Royal Southern Hospital, deposed to finding some cuts and bruises about the head and face—injuries not dangerous in themselves—and slight congestion of all the organs, the state of which in his opinion was quite

compatible with health. He gave the probable cause of death as concussion of the brain. The condition of the organs, said Mr. Knight, gave no indication of alcoholic excess. Dr. W. Whitford, called for the defence, took exception to these views. According to him, the aorta was the seat of extensive long-standing disease, the left lung almost completely solid, the right extensively solid, and the brain congested; the heart showed old-standing disease. These pathological changes, Dr. Whitford alleged, might be attributable to heavy drinking. In a case of such gravity it is to be regretted that the medical men were not agreed upon what was certain and what probable. Was the congestion of the lungs merely indicative of the mode of dying, or was it too extensive and general, as Dr. Whitford stated in cross-examination, not to have been of post-mortem origin? Had pneumonic exudation supervened on congestion? Was the cardio-aortic degeneration beyond the extent usually incidental to age? Did the alleged injuries accelerate death? These were the questions suggested by the case as a basis for investigation. We have not the slightest doubt that, whatever may have been the *predisposing* causes, the *immediate* cause of death was shock either from concussion of the brain or from the great excitement consequent on the struggle. Antecedent disease and alcoholic excess would render a man likely to succumb to injuries which under normal conditions would be insignificant.

THE OPEN SPACE QUESTION.

IT is very gratifying to us to note the success of the admirable efforts of Mr. H. R. Williams to preserve the Highgate Woods, as woods, for the use of the people of this congested metropolis. We regard the provision of open spaces in the present circumstances of the metropolis as not only a public question, but as in the first rank of public questions to which our public men should give their attention and sympathy. Not only should many existing spaces be secured in perpetuity for the delight and refreshment of the people, but steps should be taken to create more of them in some districts where they are most needed. It is difficult, however, for the most beneficent public authorities to create woods and sylvan beauty. The more credit to them when they cheerfully give those which exist, and which might have been sold for baser purposes. We give the Ecclesiastical Commissioners great credit for their generous action in this matter, and will be glad to learn that they have even determined to go further, and give the Churchyard Bottom Wood as they have given the Gravel Pit Wood. The suggestion that this should be purchased by some individual at once wealthy and generous is very good, but such individuals do not always rise to the occasion, and the needs of the millions of this city should not be dependent on personal generosity. The Ecclesiastical Commissioners would make good use of their powers by preserving more of the Highgate Woods for public use.

NURSING THE POOR.

WE lately remarked on the improvement in the art of nursing. It is also a point of improvement in Christian charity that it is trying to send a trained and cultivated nurse wherever there is a sick person untended. There are many associations of this kind in London now. This week one of the most successful of these, the North London Nursing Association for the Poor, has been holding its annual meeting under the presidency of Mr. Caine, M.P. It works chiefly in Holloway, Hornsey, Highbury, Ball's Pond, and the neighbourhood. The work done may be imagined from a few of the facts stated in the report. The number of cases under nursing care has been on an average 166 a month. The cases have included 95 of typhoid, 103 of rheumatism, 139 of acute bronchitis, pneumonia, and pleurisy, 43 of diphtheria, 39 of cancer, 79 of puerperal illness, &c. Nearly 200 medical men had referred patients to the Association for nursing help. Two of the nurses contracted typhoid fever, of whom one, an experienced and able nurse, died. This fact was fully and kindly investigated by so capable a sanitarian as Mr. Shirley Murphy, who acquitted the premises of blame, and considered that the disease had been caught by the nurses in the discharge of their duties. Much credit is due to the committee, and especially to the indefatigable and courteous treasurer, Mr. Butler, who is eminently the right man in the right place. The institution is creditable to the north of London, and should be generously supported.

DEATH FROM "INDIGESTION."

No doubt it is possible that the irritation set up by the presence of large masses of unmasticated food in the stomach may, in an exceptional case of weak heart, lead to the occurrence of syncope and death. Such a combination of evils has recently been found to produce a fatal result. The moral of this occurrence clearly must be to see that all food, and particularly that taken shortly before retiring to rest, is properly crushed by the teeth, and, which is not less important, well saturated with the secretion of the salivary glands, which it cannot possibly be unless the process of mastication be slowly performed. It is too commonly forgotten that the food needs not only to be finely divided, but to be well mixed with the saliva. Digestion, in fact, as we know, commences in the mouth, and this early stage of the process must be perfected by due elaboration if the later stages, which take place in the stomach and the intestines, are to be of avail as preparatory to absorption, assimilation, and nutrition. Artificial teeth are helpful in the performance of a necessary function when the natural teeth have ceased to be useful, and ought to be procured by all who stand in need of them. This is not a matter of vanity or taste, but one of personal expediency, of health, and even, it may be, of life itself.

SCARLET FEVER INFECTION.

AN instructive report has been issued by a medical committee appointed to inquire into an alleged recurrence of scarlet fever at a female orphan asylum as the result of the premature discharge of patients from the Netherfield Institution for Infectious Diseases at Liverpool. The precautions usually taken at that institution are of a very complete sort. The resident medical officer may not allow the discharge of any patients until he can certify them to be free from infection. In the case of scarlet fever it has not been found possible to adopt any time rule, but all convalescents are examined at least twice a week, and in order to facilitate desquamation they have a warm bath every other day. Before leaving fresh clothes are provided, and a final bath with disinfecting soap is gone through before these clothes are put on. In the case of the Orphan Institution, a further precaution was taken; for the managers removed the orphans to a house which had been taken for that purpose, and there the children were subjected to a further week's probation, after which another bath was resorted to, and then they returned to the asylum. Notwithstanding this, however, scarlet fever reappeared amongst the inmates after the return of some of the patients who had passed through all these tests. In the case of two children who returned six weeks and a half after the commencement of their illness, the asylum nurse found desquamation going on in the soles of the feet; and these cases are believed to have originated a fresh occurrence of the disease. The committee are inclined to think that the

cases in question were instances of secondary desquamation, such as are referred to in Quain's Dictionary of Medicine and in Ziemssen's Cyclopædia, and that this desquamation was the result of a much more active use of their feet than the children could have indulged in whilst in the hospital. On the general question, we would point out that final desquamation about the heels and soles of the feet is not uncommonly postponed to a later date even than six weeks and a half from the onset of the disease, and this quite apart from secondary desquamation; but as a rule we believe that the risk attendant on this late desquamation about those parts of the foot is not by any means great. Then, again, a failure thoroughly to cleanse the head is probably a by no means unfrequent source of retained infection, the desquamation of the scalp being at times mistaken for ordinary "scurf." A further source of danger receives still less attention. When children are sent to a scarlet fever hospital, it often happens that the clothing they wore a day or two before removal is stored away, and it is only brought again into use after their return home. This clothing is often infected. More than once we have heard of patients sent to hospital early in the week whose ordinary week-day clothing has been sent for disinfection, whereas that worn on the previous Sunday, having been put away, is again brought out after convalescence, and retains sufficient infection to lead to a recurrence of scarlet fever, with which the hospital and its alleged lack of sufficient precautions are certain to be credited.

A NEW SEPTIC ORGANISM.

AT the anniversary meeting of the Royal Microscopical Society, held last week, the President, the Rev. Dr. Dallinger, gave a lucid and exhaustive description of what is believed to be a septic organism not hitherto described. The new organism first came under notice about four years ago in an exhausted maceration of codfish, which had decomposed in a broth made from rabbits. The organism is of suboval shape, and measures $\frac{1}{10000}$ in. in length by $\frac{1}{17000}$ in. in breadth; it has no fewer than six long thread-like flagella, each of which is three times as long as the body. The mode of ordinary multiplication by fission presented features of much interest, owing to the problem of the formation of the new and numerous flagella. Multiplication appears also to take place by means of spores. A kind of fusion of two individuals was observed, the movement of the organism being continued during the fusion, but gradually slackening afterwards, when the body breaks up rapidly into very minute portions. The "spores" thus formed were afterwards observed to grow up into the likeness of the parent form, and shortly after to multiply by the ordinary process of fission.

LUNATICS UNDER LOCK AND KEY.

IT will, probably, be some time yet—it may be many years—before the Legislature withdraws the power of prison keeping from non-official persons. It will be still longer, we fear, before public opinion is enlightened to the extent of being able to perceive that imprisonment, whether official or otherwise, is neither an integral part of *treatment* for mental disease nor necessary for the protection of lunatics and the community. There is, however, a minor point of policy, and, as it would seem, of common humanity, which needs to be made clear, and may be not unreasonably pressed on general attention. We allude to the practice of keeping lunatics under lock and key, even when they are already safely confined within the walls of an asylum! This practice has no better excuse than the plea of economy. It costs considerably less to lock up a person of unsound mind than to provide the patient with proper attendance. This miserable—though, unhappily, all-sufficient—argument is held to be a valid one in defence and support of the practice of locking the inmates of asylums in their rooms by night, and too often by day also. Where keys are not directly turned upon the insane in "single rooms," the doors of these apartments are so constructed that they cannot be opened from within, which practically amounts to the same thing as locking the doors outside. In the event of a fire occurring, either lunatics are burnt in their prison cells, or they are released by some courageous person, perhaps the superintendent or proprietor of the asylum, at the peril or sacrifice of his life. The practice ought to be interdicted. It is a most mischievous method of "safe-keeping" at the best, and it is not one that ought to be tolerated in view of the risks necessarily entailed upon the poor folk thus treated. It will be better to be warned in time than to wait until a great catastrophe, the culminating point of a long course of mismanagement, shall compel the discontinuance of a practice obviously as dangerous as ill-advised.

CHOLERA HOSPITALS IN BOMBAY.

AN unpleasant controversy has arisen in Bombay in connexion with the subject of the establishment of cholera hospitals in the different quarters of the town. It appears that the Government have selected for the site of one of these the compound of the European General Hospital, and to it all the natives attacked with cholera in the district are to be sent. Against this selection the committee of the hospital have entered an energetic protest, and they are supported in their objections by the Surgeon-General of the Presidency, who was absent on duty when the site was chosen. His objections, as summarised in a Government general order, are "that the locating of a cholera hospital in the immediate neighbourhood of a large general hospital would be a most unwise, and indeed dangerous, procedure; unwise, inasmuch as the introduction of a disease like cholera, which the general community regard with dread and alarm, would, from the general effect produced, act to the detriment of the interests of the hospital by deterring the class of people who frequent it from attending; and dangerous, in bringing a supposed infectious disease into the immediate vicinity of convalescents, who, it is well known, are much more susceptible to infection than others in sound health; ..... that the plan proposed is in opposition to all principles hitherto laid down for the prevention of the spread of cholera." The sanitary commissioner for the Presidency does not apprehend any risk from the adoption of the site, believing, as he does, that it is clearly established that cholera is not contagious. The Government, adopting this view, adheres to the resolution regarding this hospital. We cannot but think that this decision is ill judged. The question of the transmissibility of the disease is still unsettled, and although we believe the opinion of its non-contagious character greatly predominates, it seems matter for regret that a course based on that view should be adopted which calls forth so strong an opposition as this has done. But apart altogether from the question of contagion, it appears to us most unadvisable—nay, most unjustifiable—to erect in the compound of the European General Hospital a cholera hospital for natives. The depressing effect upon the patients in the former of the perpetual recurrence of funerals, during the prevalence, to any extent, of cholera, can scarcely be over-estimated. The only circumstance which could justify the erection of a cholera hospital in such a locality would be the impossibility of obtaining another eligible site in the district, and this, we believe, is not the case. We trust that the Government will reconsider their decision and give weight to the very serious objections which have been brought before them. It is most unfortunate that they

should have adopted, on grounds which are open to dispute, a course which cannot fail to create strong feelings of opposition on the part of an influential class in Bombay, and which will, in all probability, curtail the benefits conferred by the European Hospital, at least during the prevalence of cholera. If no other site can be obtained in the district, the Government ought to assign this as a justifiable reason for the course they have adopted; if one can be had, then, in deference to the wishes of the committee and in the interests of humanity, they should without hesitation rescind the resolution and take steps to provide the requisite accommodation in some less objectionable situation.

PAROCHIAL MEDICAL LEGISLATION IN THE UNITED STATES.

OUR readers are well aware how deeply we sympathise with the large section of the profession in the United States who wish to place medical education and examination on a satisfactory footing, and to abate the number of diploma factories. The difficulties which have to be surmounted in a young and democratic country are very great. They have an illustration in the case of the State of Pennsylvania, where a Bill has been prepared to create a "State Board of Medical Examiners and Licensers." We confess we shall not be grieved if we hear of the failure of this attempt at legislation. It provides that the governor of the State shall appoint a board of nine examiners and licensers. He is to choose seven from a list of twenty-one names submitted by the Medical Society of the State, and two from a list of six submitted by the Homœopathic Medical Society of the State. The only qualifications of the examiners are that they shall be graduates of a legally chartered college, and shall have practised five years. But they must not be members of the faculties of any such college or university. Examiners selected from practitioners not teachers will, at any rate, not be very severe or exacting in anatomy, physiology, histology, general chemistry, &c., to say nothing of pathology, therapeutics, &c. The importation of homœopaths into the examining board is a violation of the rule of all European States. We quite approve of our own rule, which protects a candidate from rejection on the ground of his medical theories; but to give homœopaths a place in an examining board is another matter. But the parochialism of the legislation reaches its climax in Section 9, which provides that after the 1st of September, 1886, no person shall practise in Pennsylvania (be he graduate of Berlin, Paris, London, Edinburgh, or New York) who has not passed the gate presided over by these nine chosen practitioners of Pennsylvania. This is the story of the three tailors of Tooley-street with a vengeance. Such a Bill is not calculated to restore European respect for medical legislation in the State of Pennsylvania.

INTEMPERATE ADVOCACY OF TEMPERANCE.

TEMPERANCE in regard to stimulant drinks, as one of the leading social questions of our day, naturally gathers round it much variety of opinion. Written and spoken disquisitions upon it are common in every town and village, and vary in their cast, though not in their foundation of fact, according as the subject is considered from a moral, a sanitary, or a political standpoint. In truth, the more we widen the area of such considerations and give to each its due place, the sooner are we likely to arrive at a practical result in the direction of drink reform. The solution of the difficulty is not to be attained by pushing any one of the several theories of amendment to an unfair degree, but rather by consolidating into one remedial force the common and necessary points in which all agree. Our own view we may describe as a temperate and even an abstinent one. It does not at all ignore the great moral evil which has attended the ready and regular consumption of alcohol as a beverage, nor does it fail to observe and advocate what is now a cardinal doctrine in the hygiene of temperance—the uselessness for any good, and the frequent injury, which arises from the habitual use of stimulants by the sound in health who need no stimulation. But having said thus much, we have reached the limit which reason and fairness impose. The conditions of disease and allied states of physical exhaustion afford many instances in which we can alone rely, for the furtherance of nutrition or the support of flagging power at some crisis, on a stimulant, and it must also be admitted that at times the alcoholic form is preferable to any other. This view of the question is the one which has for long commended itself to the judgment of the medical profession, as well as probably to that of many others, not professionally interested, who have sought to guide their decision by the light of experimental and practical proofs. When, therefore we read of statements being made by extreme advocates of so-called temperance, to the effect that medical men prescribe stimulants in order to increase their practice—that is, to generate disease; that under no possible circumstances should alcohol be taken internally; and that an increasing general death-rate is the gauge of our retrogression into drunkenness, as was lately stated by Dr. J. H. Aldridge—we are bound to protest against a perversion of fair argument, which can in no case be relied upon to support any principle, however good in itself. The nature of active temperance is to do enough. If this is recognised we need place no check upon the zeal of its advocates. No real advance, on the other hand, can be expected from the teaching of those who show in their own arguments and acts the absence of that restraint which they inculcate on others in respect of alcohol.

REPRESENTATION OF THE ROYAL UNIVERSITY OF IRELAND IN PARLIAMENT.

A MEETING of graduates of the Royal University of Ireland was held on Tuesday last, presided over by Dr. Lyons, M.P., to consider the claim of the University to representation in Parliament. Resolutions were adopted to the effect that the meeting desired to express in the strongest manner its opinion that the claim of the University to Parliamentary representation should not be ignored in the Redistribution Scheme now before the House, and that a deputation should be appointed to bring the question before the Government and the Legislature. The deputation will include Drs. Charles F. Knight, Robert D. Lyons, M.P., J. Wilson, and Sir William Mac Cormac.

DR. BRADLEY'S CASE.

THE investigations made by Mr. Rice furnish strong collateral evidence of the extreme improbability, if not the absolute impossibility, of the occurrences deposed to by the prosecutrix at the assizes. It passes our comprehension on what grounds the jury convicted, if the facts related in Mr. Rice's letter were substantially put before them. We have already commented on the inconsistency of the verdict; for clearly, if the woman's evidence was trustworthy, Dr. Bradley was guilty of a far graver crime than that for which he was sentenced to two years' hard labour. Nor can it be reasonably doubted, had the Lord Chief Justice, who tried the case, been informed of the fact, on high medical authority, that confirmed epileptics are often subject during their seizures to sensations of an erotic character, he would have viewed the whole affair with even greater incredulity than he gave expression to before the grand jury. With all submission, we contend that his lordship failed to put the correct interpretation on

Dr. Bradley's alleged conduct when he concluded that the loosening of the dress about the neck, and the sending away of the patient soon after the supposed fit, were facts supporting the theory of criminal assault. Judges are not infallible, nor can they be expected to be conversant with all the details of treatment in common usage of any and every condition which medical men are called upon to attend. The case, as it stands, is so entirely unsatisfactory, that it is not only advisable, but necessary, in the interest of justice, that it should be reopened. The Home Secretary can scarcely fail to order a commission of inquiry when the largely and influentially signed petition is laid before him. Since writing the above, we have received copies of memorials to the Home Secretary, from a large number of medical men in Nottingham, Chesterfield, and the adjoining districts, including the staffs of the public medical institutions in Nottingham and Chesterfield.

THE ELECTION OF HOUSE-SURGEON AT THE DONCASTER INFIRMARY.

WE learn that the recent election of a gentleman to fill the office of House-Surgeon to the Doncaster Infirmary and Dispensary was the occasion of a slight misunderstanding between the medical staff of the institution and some of the governors. It appears that the applications and testimonials of the thirty-eight candidates for the post were submitted to the staff for them to determine the question of eligibility for the office. But in their report the Medical Committee selected one gentleman as the candidate to be recommended to the governors for election. This appears to have given umbrage to some of the lay governors, and at the vote subsequently taken another gentleman was elected. We have nothing to say on this question as to whether the Medical Committee went beyond its privileges as detailed in the rules of the institution. But the general question is of wide interest. It appears to us that it is of the very highest importance to the prosperity of a hospital or infirmary that the resident medical officers who have to carry out the wishes of the visiting medical staff should possess the thorough confidence of the individual members of that body, and should realise to the full their responsibility to them, and look to them for support and approval. And therefore it is always found to conduce most to the harmony of these institutions to leave it to the staff to recommend to the Board or Governors generally the candidate they feel to be most acceptable to them. The staff are also able to judge best between the professional claims of rival candidates. When other modes of election are resorted to canvassing becomes necessary, and it is vain to hope that merit will always receive its just reward.

OUTBREAK OF TYPHUS IN CAMBERWELL.

UNDER the influence of increased sanitary energy and of improved sanitary organisation, typhus is becoming a rare disease in most of our large towns. After making due allowance for the improvement in the diagnosis of "fevers," the deaths referred to typhus have rapidly declined in recent years. In London, for instance, the deaths attributed to this cause have steadily declined from 716 in 1869, to 31 in 1884. There is, moreover, good ground for believing that of these thirty-one a considerable proportion were not cases of true typhus. Only thirty cases of typhus were admitted to the metropolitan asylum hospitals during last year, of which six terminated fatally. By the light of these figures the fact reported in the Registrar-General's last weekly return, that nineteen cases of typhus were admitted to these hospitals during the last week, is particularly noteworthy, more especially as the whole of them were admitted from Camberwell. It appears that a remarkable outbreak of typhus has occurred in that part of the Camberwell district known as New Peckham, as thirteen of the nineteen cases were admitted from Bexley-place, Bexley-alley, Downes-street, and Lower Park-road. In connexion with this outbreak, it may be noted that in the latter part of December a fatal case of typhus occurred in one of the metropolitan asylum hospitals that had been admitted from Verney-flats, Rotherhithe New-road, also situated in New Peckham, close to the locality of the present outbreak. The occurrence of this case should have been a warning to the local sanitary authority, which, however, would appear not to have been correctly informed as to the nature of the outbreak, as we believe that the recent cases, or at any rate a considerable number of them, were admitted to hospital as enteric fever cases.

"A WORD OF WARNING TO OXFORD MEN.

A CORRESPONDENT of the *Pall Mall Gazette*, signing himself "B.A.," has been a little too hasty in giving a "word of warning to Oxford men" upon the proposal that the University should recognise the final examination for medical diplomas of the two London Colleges as equivalent to passing an examination in precisely the same subjects and on precisely the same lines at Oxford. There is not the slightest intention to throw open the doors of the University to all holders of these diplomas; the Oxford graduates will still be required to fulfil the present University curriculum, and none but they will be enabled to present themselves for its medical degrees. As a matter of convenience, and of common sense, such graduates, who at the present time spend at least two years in acquiring clinical knowledge at the London hospitals, ending in the examinations of the London Royal Colleges, will pursue this course in future; but they will, supposing the scheme receive the sanction of Convocation, be exempt from the burden of submitting to two examinations on the same subjects. In order, however, that the University may establish its right to confer a stamp upon its graduates signifying that they have attained higher qualifications than the ordinary medical student, evidence of such higher knowledge, in the form of a thesis, will be required. The University will still conduct its purely scientific examinations, and it will remain, therefore, still true that, as "at present, no one is admitted even to the first examination for the Oxford Medical who has not taken his B.A. degree in the ordinary manner." Such is, we believe, the proposition that has so greatly alarmed the correspondent of our contemporary, and it seems to be one which will be of advantage all round.

DEATHS FROM HURRY AND EXERTION.

A FEW days since, a railway clerk, aged twenty, was found dead in a sitting posture in a second-class railway carriage when it arrived at Woolwich. At the inquest it was stated that deceased had been suffering from heart disease for two or three years, and it was supposed that he had hurried to catch the train that morning. The surgeon who made the post-mortem examination stated that the heart was enlarged. Another case of death from exertion in a man suffering from diseased heart occurred on the 11th inst. A signalman at Brixton railway station, while pulling one of the levers, suddenly fell backwards, and on the arrival of a surgeon was pronounced to be dead. The widow stated at the inquest that deceased had been treated for an affection of the heart for some time. In this case there does not seem to have been a post-mortem examination. Yet another death from exertion occurred on the 12th inst. A young lady, aged sixteen, expired suddenly in a gymnasium after performing a feat of skill. According to the medical evidence she was suffering from valvular disease of the

heart. How often has the hurry to catch a train, or some other sudden exertion, throwing extra work on a dilated, fatty, or otherwise diseased heart, resulted in fatal syncope! It is our duty to warn such patients of the risk they will run if they allow any consideration of business or convenience to tempt them to a single rash act of this kind.

KÜSSMAUL'S COMA.

THE group of symptoms which have been designated by the inexact name of "Küssmaul's coma" consists chiefly of slow and laboured respiration, rapid cardiac action, restlessness and pain, apyrexia, glycosuria, and paralytic distension of the stomach. An article containing a large amount of information on the literature of this subject has been written by Dr. Saundby in the *Birmingham Medical Review*. There seems to be no doubt that this group of symptoms may be met with in morbid states of the system unaccompanied by glycosuria. That the symptoms are caused by a poisoned condition of the blood seems most probable. It may be well to point out that two of the chief symptoms may be explained on the assumption of paralysis of the vagus nucleus. The slow and laboured respiration somewhat resembles that form of dyspnœa which is the result of section of both vagi; the acceleration of the heart's action might be attributed to the more or less complete removal of the inhibitory cardiac functions of the vagus nucleus. Whether damage of the vagus nucleus can determine paralytic distension of the intestines must remain a purely speculative question. Epigastric pain or distressing sensations about the epigastrium have been referred, in epileptic seizures, to central disturbance of the vagus paths. We have not the least bias in favour of the supposition that all the symptoms of so-called Küssmaul's coma are due to interference with the vagus nucleus, though it may be well to consider the claims of such a suggestion. Alkaloids have a selective action on many parts of the nervous system, and there is the bare possibility that Küssmaul's coma may be the work of some alkaloid having a selective action on the vagus centres.

THE ANTI-VACCINATION ACTS AT LEICESTER.

LEICESTER will one of these days be very rudely undeceived on the subject of vaccination. The accumulation of unvaccinated children is going on apace. The fool's paradise in which the defaulting parents are living is all very well till the day of small-pox comes, and then they will find how pregnant with death and disaster this disease is, from which science and beneficent legislation have provided a protection that, generously used, might be made all but absolute. Meantime it is the duty of the Legislature to take prompt measures for making the Acts more efficient.

LINCOLN WATER-SUPPLY.

THE question of the wholesomeness of the water-supply for the city of Lincoln was the subject of a lengthened discussion at the last meeting of the Town Council. The water has been under suspicion, and hence analyses have been ordered. But the Local Government Board have informed the sanitary authority that knowledge of the chemical ingredients of a water, however complete, does not suffice to form an opinion of its wholesomeness, and they have urged that examination of the several sources of supply should be made in order to ascertain what are the risks of contamination to which they may be subjected. Mr. Councillor Watkins evidently saw the importance of this examination, but a worthy alderman held a different view. Mr. Alderman Maltby declared that if he knew anything about analyses he he was satisfied that there could be no germs of disease about a water that had been pronounced by an analyst to be chemically pure. The little word *if* makes the alderman's statement an eminently safe one. But before the matter again comes under discussion we would advise the alderman to increase his knowledge of the subject by reading the report to which the Local Government Board has drawn the attention of the Council, and he will there find that a water to which a filtrate of typhoid excrement had been deliberately added was found, in the hands of a leading analytical chemist, to give results which would have enabled him to class it as one of organic purity. "Polluting material, potent for harm," according to that report, "may be present in a water..... without removing it from the rank of waters" classed by the chemist in question as of "extraordinary organic purity."

UNIVERSITY COLLEGE HOSPITAL.

SOME changes are about to occur in the surgical staff of University College Hospital. The chair of Surgery at the College and the post of Surgeon to the hospital are vacant by the resignation of Professor J. Marshall, F.R.S. The post of anæsthetist to the hospital, which has been vacant since the death of Mr. Clover, has recently been filled by the election of Dr. Dudley W. Buxton to the office.

THE INSPECTION OF PARIS HOTELS.

THE Paris Prefect of Police, M. Camescasse, has just issued a decree reorganising the service for the inspection of lodging-houses, hotels, &c. There are to be six inspectors and four assistant inspectors, who will divide Paris between them into ten districts. They will visit every hotel or lodging-house at least once a year; but all new establishments of this description must be inspected within five days of their first opening. On the outbreak of any contagious disease, the inspector of the district must at once examine the place and report whether any special measures are necessary. To this ordinance we would object—first, that the number of inspectors for such an immense town as Paris is altogether insufficient; and, secondly, that a large portion of the more unwholesome lodgings of Paris have already been visited by the Commission des Logements Insalubres. Eloquent reports have been issued by Dr. Dumesnil and other members of this commission; but, broadly speaking, nothing has been done. If the appointment of a new body of inspectors can infuse fresh energy into the minds of the superior authorities, then some good will result, otherwise we fear that the new decree of the Prefect of Police will only tend to engender a sense of false security.

COLLECTIVE INVESTIGATION OF DISEASE.

THE Medical Society of the State of Pennsylvania have formed a committee to carry into effect a scheme of collective investigation, on the same lines as that initiated by the British Medical Association. Cards upon acute pneumonia, chorea, and acute rheumatism, drawn up precisely like those of the latter Association, have been circulated, with the request that returns be made not later than the 1st day of April, 1885, in order that reports may be compiled for presentation to the annual meeting of the Society in May. The committee point out that by adopting the British method without alteration it has secured the advantages of uniformity, and thus enabled the scheme to have an international application. In Germany the first report of the Collective Investigation Committee dealing with tuberculosis has been published in the *Zeitschrift für Klin. Medicin*, Bd. 8, Heft 6. The inquiry embraced a very wide field, and only about two hundred replies were received, several of which had to be rejected owing to their incompleteness. It is not considered that the results as yet obtained embrace a sufficiently large number to draw any very definite conclusions therefrom.

THE CHEAPNESS OF QUININE.

QUININE is said to be cheaper almost than it has ever been. Few facts are more important to mankind, next to the price of wheat and meat. In our temperate climate the price of quinine is of less interest than in hot climates and marshy regions. Yet with us how large is the scale of its use, and how specific the benefits which it confers in neuralgia, in puerperal and other pyrexiæ, in rheumatic fever, and in debility of all kinds. But in tropical countries, and especially for Europeans in these, it is almost essential to the preservation of life. In these days of Suez and Panama Canals, of African exploration and colonisation, and of Nile expeditions, the cheapness of quinine is of pleasant and prodigious consequence. It would be very instructive if there were attached to all these undertakings a subordinate of the Registrar-General. We should then know on what a scale life is sacrificed where quinine is withheld, and how unequal is the risk to the rich man who has the quinine and the poor man who has it not. With the growing cheapness of quinine there will be less excuse for this discrepancy in the future.

SMALL-POX IN THE METROPOLIS.

SMALL-POX has made further progress in the metropolis during the past fortnight, and the managers of the Asylums Board have in consequence addressed the various boards of guardians, urging upon them to make house-to-house visitations with a view of securing the vaccination of children whose primary vaccination has been neglected, and the revaccination of others.

THE BOWER AND KEATES FUND.

As inquiries have been made in regard to the settlement of this fund, the honorary secretary (Dr. R. W. Burnet) desires us to state that the plaintiffs having obtained motion for a new trial, and having as yet taken no further action in the matter, the committee cannot issue a statement until the case is finally settled.

A STATEMENT has been published of the numbers and nationality of the medical practitioners who have recently attended the special courses held by Dr. Koch at the Imperial Board of Health, from September to January, upon the methods of investigation employed in cholera research. Eleven courses were given, consisting of about ten days each, and the total number of those sharing in them was 191. The large majority were from various parts of Germany, but the list includes twenty foreign practitioners—from Austro-Hungary, Russia, Great Britain, Italy, Spain, Sweden, Luxemburg, North America, and Australia.

THE death of Dr. Edwin Samuel Gaillard, the proprietor and editor of *Gaillard's Medical Journal*, is announced as having occurred at his home in Ocean Beach, N.J., on the 2nd inst. Dr. Gaillard was born in 1827, graduated from the South Carolina Medical College in 1854, and, after practising in Florida and New York, joined in 1861 the Confederate army, following until the close of the war the fortunes of the South. At the close of the war Dr. Gaillard practised for three years in Richmond, moving afterwards to Louisville, and finally to New York.

WE learn from the *Bombay Gazette* that at the very last moment, and, indeed, after the official order on the subject was in print, the matter of Dr. Payne's claims to the Surgeon-Generalship of Bengal has been reopened by the Government of India.

JAMES HENRY BROOKS, M.R.C.S., L.S.A., of Mahé, Seychelles, eldest son of the veteran Dr. Brooks of Henley-on-Thames, was on the 6th inst. duly created a Knight of the Order of Pius the Ninth and received into the Society of that Knighthood by the mandate of Pope Leo XIII. This is not a religious order, but is established—as it is set forth in the decree—"to confer the highest honours and titles upon those who to the merit of science and wisdom join the habitual practice of charity."

THE *Indian Medical Gazette* prints an excellent letter from a "Correspondent on Furlough," containing some sound advice on "where and how to spend it." We would commend this to the notice of our medical brethren in Her Majesty's Indian Medical Service purposing taking furlough to Europe.

IN the legal proceedings instituted by Mr. Walter Hasker, who was confined as a lunatic in Bethlem Hospital in the autumn of 1883, against a medical man who signed a certificate, a solicitor, and Dr. Savage of Bethlem Hospital, the judges decided that Dr. Savage should permit an inspection of the case-book on behalf of the plaintiff.

THE death is announced, at the age of eighty-eight, of the Master of Downing College, Cambridge, which includes a large medical element. Professors Humphry and Latham both belonged to Downing until King's elected the former to a Fellowship.

COLONEL TALBOT, who commanded the convoy which was attacked by the Soudanese on the 13th inst., in his despatch describing the encounter especially reports upon the excellent work done by Surgeon-Major Conolly.

IN a case of tubercular meningitis supervening upon lupus Dr. Doutrelepont (*Deutsch. Med. Wochenschrift*, 1885, No. 7) reports the detection of tubercle bacilli in blood removed from the heart and jugular vein.

MR. W. K. HATCH, M.B., M.R.C.S., has been appointed to act as Medical Officer on the personal staff of his Excellency the Governor of Bombay, vice Mr. J. Findlay, M.B., C.M., appointed Surgeon to his Excellency the Viceroy.

SMALL-POX has broken out with considerable virulence at Pudsey, and a number of cases have been removed to the Bradford Fever Hospital. The disease is stated to be rife also at New Brompton.

THE appointment of Privy Councillor Köhler to the directorship of the German Imperial Board of Health in succession to Dr. Struck is announced.

DR. R. HERTWIG has been nominated Professor of Zoology at Munich, and Dr. C. Flügge has been placed on the professoriate of Göttingen University.

THE Cambridge Improvement Commissioners have arranged to have two more special reports respecting the proposed new drainage system.

DR. MÜNTER, Professor of Botany at the University of Greifswald, died on the 2nd inst., in the seventieth year of his age.

Pharmacology and Therapeutics.

THE ST. DALMAS' CHEST AND BACK PLASTERS.

THESE are perforated plasters spread on scarlet felt. There are several varieties, the most generally useful being the ordinary strengthening plaster and the plasters of belladonna and capsicum. They are useful and deserve a trial.

CINCHONIDINE AND PICROTOXINE.

The following conclusions have been arrived at by Dr. Chirone as the result of a careful series of experiments on animals with bisulphate of cinchonidine and with picrotoxine. 1. There are poisons like cinchonidine and picrotoxine which are capable of causing genuine epileptic attacks. Cinchonidine acts chiefly by irritating the cortical motor centres, and picrotoxine acts on the centres in the medulla oblongata. 2. Cinchonidine does not cause convulsion in animals from which the brain has been removed; when certain of the motor centres have been taken away the convulsions do not occur in those groups of muscles innervated by the removed centres. Picrotoxine, however, has a toxic action of a more energetic kind on the same animals. 3. The convulsions called forth by these poisons, although of an epileptiform nature, nevertheless present notable differences even in the same animal; animals are affected according to the degree of development of their nervous system, and according to special circumstances of their existence. All vertebrated animals are affected, even amphioxus. The invertebrated animals present no phenomena when treated by these agents. 4. Cinchonidine, whilst killing rabbits, does not always cause epileptic phenomena; these animals, however, do react to picrotoxine. 5. Cinchonidine does not, though picrotoxine does, cause convulsive phenomena in hibernating animals, at all events during summer. 6. In the higher mammals the convulsions of cerebral origin induced by cinchonidine always commence in the muscles of the face, and extend gradually to those of the neck, front limbs, and so forth. The convulsions due to picrotoxine generally commence with tremors of the head or of the entire body. The spasm from cinchonidine at the onset is clonic, whilst that of picrotoxine is at the outset tonic. The ocular muscles and those of the pupil and tongue take but little part in the phenomena induced by cinchonidine, whilst the reverse holds good for picrotoxine. Picrotoxine causes a cadaveric rigidity, which is seen before, and persists a long time after, death; whilst cinchonidine does not disturb the usual phenomena of post-mortem rigidity.

NAPHTHALINE IN CYSTITIS.

Naphthaline, one of the solid products of petroleum, insoluble in water, has been recommended for internal administration by Rossbach in cases of cystitis with ammoniacal urine. Dr. Cushing lately spoke of its value at a meeting of the Suffolk Medical Society (U.S.), citing a case where he had given powders containing about two grains of the drug in wafers or capsules mixed with water or flaxseed tea. Before the treatment was commenced the bladder had been washed out daily with carbolic solutions, and on the second day of the naphthaline treatment all foul odour had disappeared. Subsequently local treatment with boracic acid injections was combined with naphthaline internally. Naphthaline appears to have a most powerful antiseptic action, and Rossbach was led to its employment in cystitis by noting that it arrested fermentation of urine. The formula recommended by Rossbach is:—℞ Naphthalini puriss., sacch. alb., āā 5·00 grammes; ol. bergamottæ, ·03 gramme. M. fiat pulv. No. xx.

A SPURIOUS CUBEB.

The *Pharmaceutical Journal* states that a spurious cubeb has been recently offered in the London market. It consists of the fruit of Daphnidium cubeba, which closely resembles cubebs in general appearance. According to Loureiro, these fruits are used by the Cochin-Chinese as a nervine tonic in paralysis, vertigo, melancholia, and other nervous disorders. The fresh fruits are used for preserving fish, and hence, probably, contain some antiseptic agent. The Chinese, according to Porter Smith, use the fruits for bronchitic, dyspeptic, cystic, and choleraic affections.

CONIUM MACULATUM.

Orfila states, in his Traité de Toxicologie, that having administered large quantities of the juice of conium maculatum to a dog, he was surprised to find that no effect was produced. The root of the plant would appear, therefore, to differ from that of aconite and of belladonna in being very poor in alkaloid. M. Lepage of Gisors has worked at this subject, and confirms the statements of Orfila. The largest quantity of conicine was found in the fruit of the plant.

AUSTRIAN MEDICAL STATISTICS.

THE Austrian statisticians work very carefully and correctly, but too slowly. Only a few days ago the report of the I. a. R. Central Board for Statistics, which deals with the sanitary condition of the Austrian provinces (those which belong to Hungary excepted) in 1881, appeared. The most important data, which are of interest also for foreign physicians, are the following:—

In 1881 there were 159 public hospitals, containing 19,731 beds and 118,156 patients; and 375 private ones, containing 9436 beds and 67,477 patients. On an average, 1 per 82 inhabitants sought relief in a hospital; 53 hospitals containing 2776 beds and 37,744 patients belonged to religious orders. The largest hospital on the Continent is the I. a R. "Allgemeine Krankenhaus" (universal hospital) in Vienna, containing 20 divisions, amongst which 5 for internal medicine, 3 for surgery, 2 for syphilis, 1 for diseases of women, 1 for diseases of the eye, 1 for chest diseases, 1 for cutaneous diseases, 1 for mental debilities; further, the division of the Union for the protection of sick students "(Studentenkrankenverein,") and 2 divisions, 1 for internal and 1 for external medicine, for well-to-do people. These divisions are managed by 13 chief physicians and 39 assistants. This hospital possesses, besides these divisions, 13 clinics viz., 2 for internal medicine, 2 for surgery, 2 for ophthalmology, 2 for gynæcology, 1 for syphilis, 1 for dermatology, 1 for laryngology, 1 for otiatria, and 1 for mental debilities. On an average 25,000 patients are yearly treated in this institution.

The number of lunatic asylums amounted to 27, of which 22 are public and 5 private, containing 7002 beds and 9694 patients. Of these patients 646 that is, 6·7 per cent.—were cured; 1692 (17·4 per cent.) were dismissed still insane or transferred to another hospital; and 1237 (12·8 per cent.) died; so that at the end of the year 6119 (63·1 per cent.) remained under treatment.

	Males.		Females.	
Unmarried	32·0	per cent.	24·1	per cent.
Married	20·8	„	15·6	„
Widowed	2·2	„	5·3	„
Total	55	„	45	„

On an average, out of 100,000 inhabitants 42 were insane, inferring from those who were treated in these asylums. As to the age of the insane, the official statistics show the following figures:—

Under 10 years	0·2 per cent.
Between 10 and 15 years	0·8 „
„ 15 „ 20 „	5·1 „
From 20 to 25 „	9·8 „
„ 25 „ 30 „	13·1 „
„ 30 „ 40 „	29·4 „
„ 40 „ 45 „	13·5 „
„ 45 „ 50 „	10·5 „
„ 50 „ 55 „	7·3 „
Insane aged over 55 „	10·3 „
Total	100·0

As to creed:—

91·1 per cent.	Roman Catholics.
1·9 „	Protestants.
0·4 „	Greek Oriental.
6·6 „	Jews.

Outside of the asylums the insane numbered at the end of 1881 (only in the Austrian provinces) 20,001—that is, 91 per 100,000 inhabitants.

The number of cretins amounted to 15,151—that is, 69 per 100,000 inhabitants. In the Alps, especially in Carinthia, their number increased enormously—for instance, in the district of Murau the proportion of cretins to the population was 1078 to 100,000.

Eighteen public lying-in institutions existed, with 1486

beds, 17,483 mothers, and 16,165 children, whereof 127 mothers, or 0·72 per cent., and 1013 children, or 6·27 per cent., died; 15,987 births were registered; out of 1000 deliveries 13·3 were twin births and 0·006 triplets.

Twelve foundling hospitals existed, with 448 beds for the children and 256 beds for the wet-nurses. The children are retained in these hospitals only a short time, and then delivered to foster-parents. The rate of mortality of the children in the hospitals amounted to 6·08 per cent., whereas that of the children with foster-parents reached 12·83 per cent.

Fifteen institutions for the deaf and dumb existed, with 1284 inmates, whereof 47·7 per cent. were born deaf and dumb.

Nine establishments for the education of blind people existed, with 476 inmates at the beginning and 445 at the end of the year, whereof 14·6 per cent. were born blind, 79·2 per cent. became blind through diseases, and 6·2 per cent. through accident.

In fourteen institutions for vaccination 11,835 lancets impregnated with vaccine matter and 11,627 phials were sold.

Austria possesses 206 bathing places, which were visited by 106,087 persons. The Tyrol has the greatest number of bathing places—namely, 80; whereas the Bohemian places (22) had the greatest number of visitors—namely, 69,016.

The number of physicians amounted to 7427 (4766 doctors and 2661 surgeons, who, in Austria, rank lower than the doctors). On an average, there is one physician to every 2500 inhabitants; but in Galicia there is one to every 7209 inhabitants; whilst in the towns—for instance, in Innsbruck one to 390, and in Vienna one to 639 inhabitants. The number of midwives amounted to 16,298—one midwife for every 1348 inhabitants.

Per 100,000 inhabitants, 3164 (3·164 per cent.) died. The highest rate of mortality was registered in Bukowina, 3·764 per cent.; the next highest rate in Galicia, 3·653 per cent.; the lowest rates in Dalmatia, 2·137 per cent., and in the Tyrol, 2·455 per cent. Per 100,000 male inhabitants 3387 died, whilst from an equal number of female inhabitants only 2953 died. The proportion of male self-murderers to female is 4½ to 1.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In twenty-eight of the largest English towns 6352 births and 3571 deaths were registered during the week ending the 14th inst. The births exceeded by 538, while the deaths were 56 below, the average weekly numbers during 1884. The annual death-rate in these towns, which had been equal to 24·5 and 21·8 per 1000 in the preceding two weeks, further declined last week to 20·9. During the first six weeks of the current quarter the death-rate in these towns averaged 23·4 per 1000, against 24·7, the mean rate in the corresponding periods of the five years 1880-84. The lowest death-rates in these towns last week were 13·5 in Birkenhead, 15·1 in Salford and in Derby, and 16·8 in Brighton. The rates in the other towns ranged upwards to 27·5 in Norwich, 31·2 in Preston, 32·3 in Cardiff, and 32·5 in Sunderland. The deaths referred to the principal zymotic diseases in the twenty-eight towns were 398, against 397 and 356 in the preceding two weeks; they included 112 from whooping-cough, 91 from measles, 53 from scarlet fever, 41 from "fever" (principally enteric), 40 from small-pox, 35 from diphtheria, and 26 from diarrhœa. No death from any of these zymotic diseases were recorded last week either in Brighton or in Plymouth; whereas they caused the highest death-rates in Norwich, Cardiff, and Sunderland. The highest death-rates from whooping-cough occurred in Preston and Nottingham; from measles in Cardiff, Huddersfield, and Sunderland; from scarlet fever in Leicester and Preston; and from "fever" in Norwich. The 35 deaths from diphtheria in the twenty-eight towns included 16 in London, 9 in Liverpool, and 2 in Nottingham. Small-pox caused 57 deaths in London and its outer ring of suburban districts, 3 in Birmingham, 2 in Sheffield, and 1 in Liverpool. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which had been 1146 and 1144 on the preceding two Saturdays, had risen to 1223 at the end of last week; a higher number than has been under treatment since July last; the cases admitted last week were 255, against 287, 253, and 223 in the preceding three weeks. The Highgate Small-pox Hospital contained 96 patients on Saturday last, 29 cases having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had been 556 and 421 in the preceding two weeks, further declined to 383 last week, and were no fewer than 238 below the corrected weekly average. The causes of 84, or 2·1 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Brighton, Leicester, Salford, and in six other smaller towns. The largest proportions of uncertified deaths were registered in Oldham, Preston, Derby, Halifax, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual death-rate in the eight Scotch towns, which had been equal to 30·2 and 26·6 per 1000 in the preceding two weeks, further declined to 25·0 in the week ending the 14th inst., but exceeded by no less than 4·1 the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 15·8 and 16·6 in Edinburgh and Perth, to 26·8 in Greenock, 28·0 in Dundee, and 29·6 in Glasgow. The 609 deaths in the eight towns included 29 which were referred to whooping-cough, 25 to measles, 13 to diarrhœa, 12 to scarlet fever, 10 to "fever" (typhus, enteric, or simple), 6 to diphtheria, and not one to small-pox; in all, 95 deaths resulted from these principal zymotic diseases, against 98 and 92 in the preceding two weeks. These 95 deaths were equal to an annual rate of 3·9 per 1000, which was 1·6 above the mean rate from the same diseases in the twenty-eight English towns. The 29 deaths from whooping-cough showed a decline of 5 from the number in the previous week, and included 7 in Glasgow, 5 in Dundee, 5 in Leith, and 4 in Greenock. The 25 fatal cases of measles showed a further increase upon recent weekly numbers; 17 occurred in Glasgow, 5 in Dundee, and 3 in Aberdeen. The 13 deaths attributed to diarrhœa showed an increase of 3 upon the number in the previous week, and were 3 above the number in the corresponding week of last year. Ten of the 12 deaths from scarlet fever, and 7 of the 10 referred to "fever," occurred in Glasgow. The 6 fatal cases of diphtheria were fewer than those in the previous two weeks, and included 3 in Glasgow and 2 in Dundee. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 214 and 189 in the previous two weeks, further declined to 152 last week, but were 43 above the number returned in the corresponding week of last year. The causes of 80, or 13 per cent., of the deaths in the eight Scotch towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 31·9, 35·5, and 36·2 per 1000 in the preceding three weeks, was 34·9 in the week ending the 14th inst. During the first six weeks of the current quarter the death-rate in the city averaged no less 33·5 per 1000, the mean rate during the same period not exceeding 22·6 in London and 21·6 in Edinburgh. The 236 deaths in Dublin last week showed a decline of 9 from the number returned in the previous week, and included 20 which were referred to the principal zymotic diseases, against 23, 22, and 18 in the previous three weeks. Of these 20 deaths, 10 resulted from measles, 4 from "fever," 3 from scarlet fever, 2 from whooping-cough, 1 from diarrhœa, and not one either from small-pox or diphtheria. These 20 deaths were equal to an annual death-rate of 3·0 per 1000. The rate from these diseases last week was equal to 2·1 in London and 1·7 in Edinburgh. The fatal cases of measles in Dublin, which had been 3 and 5 in the preceding two weeks, rose to 10 last week. The deaths from "fever" (typhus, enteric, or simple) corresponded with the number in the previous week, while the fatal cases of scarlet fever showed a decline. Three inquest cases and two deaths from violence were registered within the city; and 76, or nearly a third, of the deaths were recorded in public institutions. The 46 deaths of infants exceeded the number in any previous week of this year, while those of elderly persons had declined. The causes of 35, or nearly 15 per cent., of the deaths in the city last week were not certified.

"Audi alteram partem."

EPIDEMIC INFLUENZA.

To the Editor of THE LANCET.

SIR,—It seems not improbable that England during the coming months may be again visited by epidemic influenza. There are rumours of curious chest attacks, which have affected households with fatal severity. I have heard these illnesses described as epidemic pneumonia; evidently the disease is of a highly contagious character. Within my own knowledge are four families suffering from such contagious chest trouble; and within the past few days I have had another family under my own care, in which the disease assumed such peculiarities as to lead me to infer that I had to deal with true influenza. The facts of the case are as follows:—

On the morning of Saturday, the 31st ult., I was asked to see a child aged fourteen. I learned that on the previous day there had been no indication of illness. The child had gone to bed fairly well, but had passed an extremely feverish, restless night. I first saw my patient at 9 A.M., the symptoms being those of high fever, with a temperature of 103·5°; breathing very rapid and shallow, about 60 to the minute; pulse 140. I could detect no changes in the chest sufficient to account for these grave symptoms, and as far as I could ascertain all the other organs were healthy. I have seen such conditions precede a severe catarrh in children of a neurotic type, and I thought probably such was the case before me. In the evening of the same day, at 5 P.M., all the symptoms were intensified; but in addition there were symptoms of acute fully developed bronchitis, the most extraordinary point being that the expectoration was both copious and purulent, such an expectoration as would be seen after several days of sharp bronchitis. The pulse was still as rapid as in the morning, the breathing more so. The temperature was now 105·5°, the cough incessant, and the tongue covered with thick creamy fur. There was great prostration, but no delirium, the mind being perfectly clear. Physical examination of the chest discovered almost universal bronchitis of the large and small tubes. I should describe it as being more patchy or lobular than is usual; if it had not been so, I fail to see how respiration could have been carried on. During the day two other children in the same house had been seized with a similar attack, though in a less intense form, the extreme fever being perhaps the most marked symptom. On the following morning—that is, within thirty-six hours of the commencement of the attack—in the case of the first child the storm had completely passed. The bronchial irritation had continued until about midnight, when it almost suddenly ceased. The child fell asleep, and passed a good night. At the time of my visit the pulse and temperature were normal, the breathing tranquil, and I could scarcely detect a râle in the chest, a heavily coated tongue, great prostration, and complete loss of appetite being all the traces left of the attack. With the other two children the bronchial attack was not so severe. But in the case of one it was marked and peculiar with regard to its rapid accession and its rapid decline, all stages of acute bronchitis being passed within a few hours, thirty at the most. On the third day one of the children was much troubled with severe earache, which is one of the common sequelæ of influenza. I should also add that during this short illness a dog in the house had an attack of marked bronchial character, and apparently of the same type as that seen in the children.

It is now so many years since England was visited by epidemic influenza, that it would be well for practitioners to be on their guard against its possible advent; the mortality during its last occurrence was terrible. Ten years ago I had a family under my care, and at that time I regarded their highly mysterious illness as caused by influenza. Subsequent knowledge leaves no doubt on my mind that it was a sporadic form. A family of seven children were suddenly struck down by simple continued fever, in each case complicated by some form of chest trouble of a catarrhal character. The fever in each case ran high, and in two the bronchitis was most severe, though not so severe as in the case I have related above. The acute stage passed rapidly off, and was followed in each case by earache, and left that peculiar prostration which I have always understood to characterise true influenza. It is a prostration which reminds one of that following diphtheria, and which suggests a neurotic origin, probably through some poison affecting the pneumogastric. The enfeeblement which follows diphtheria has no direct connexion with the extent of throat trouble, a very slight throat affection being often succeeded by prolonged prostration. As with epidemic influenza, a slight attack may leave the patient miserably weak.

One word as to treatment. I presume no physician of the present day would care to follow the advice laid down by our older writers. The lancet and calomel must be replaced by quinine, brandy, and good nourishing soups. The pyrexia can be at least assuaged by judicious sponging. Under some such treatment, we may trust that, should this formidable enemy again attack us, the mortality will show a marked improvement over that of the last great epidemic, so graphically described by Sir Thomas Watson in his lectures.

I am, Sir, obediently yours,

DONALD W. CHARLES HOOD.

Green-street, Park-lane, February, 1885.

CONGENITAL DISLOCATION OF THE HIP.

To the Editor of THE LANCET.

SIR,—I am reminded of the fable of the wolf and the lamb when Dr. Bennett complains that I have attacked him. I was under the impression that he had attacked me, and that his attack was neither polite nor measured. He introduced my name nine times, misspelt, into his address, and evidently thought that he had, wolf-like, given me the *coup de grâce* when he uttered the words "falls to the ground." Also, he complains that I have perverted ("twisted") his description of the pathological wasting of the gluteus; that I have attributed "nonsense" to him, and have put into his mouth "absurd statements." But I have merely used his own words, and the conclusion is that which naturally arises out of them. He thinks that I have overlooked the word "almost," but he will find that I have quoted him exactly. With your permission I will transcribe the paragraph which he complains that I have mutilated. It runs thus: "The next of the series of theories was that of Ammon namely, that it was due to arrest of development. That theory naturally suggested itself first, and in dissecting the specimens I have kept it prominently before me, but I see no evidence of arrest of development as the cause of dislocation. The epiphyses and the shaft of the femur are normal, except so far as they have suffered from the effects of the dislocation. The most important theory was that of Guérin, that during fœtal existence some irregularity of nerve action occurred, and the muscles in particular groups became affected for the time spasmodically. Whatever the change was, whether spasmodic action of muscle or simple disorganisation of muscle of any kind, it was followed by retraction of the muscle, and that retraction caused the displacement. In my own cases I have been struck with the destruction of the fibres of the gluteus maximus muscle—indeed, they had almost disappeared in places." Which, being explained and reduced to few words, means this: There is no arrest of development, but retraction following intra-uterine spasm caused displacement of the head of the femur and destruction of the fibres of the gluteus. If there is any other meaning attaching to it, perhaps Dr. Bennett will say how he understands it. He thinks that I overlooked the fact that he exhibited four examples dissected and preserved by Harrison, as well as two of his own. In this address the numbers of specimens are not given, and no single one is described. Notwithstanding his dissections, Dr. Bennett does not formulate a theory; but he has come to a wrong conclusion—namely, that every recorded dissection reveals facts identical with those seen in Hutton's case. He is grand at fault-finding, and scolds, all round; and yet he can only avow his ignorance of the subject.

Dr. Bennett assumes too much; he assumes that I have not made any dissections. Both I and others have made dissections, and some of them are published, and my paper was based on them. Further, he exhibits considerable credulity. Hutton's case is not one of congenital dislocation; but if it were, who would believe that the position of

the displaced head of the femur in a partially paralysed idiot of thirty-one years could be similar to that observed in a young and healthy child, and who would think it fair to draw a comparison between cases so dissimilar, or who would think that "*the true position of the head of the femur*" could be learnt from such a case except Dr. Bennett? It is impossible to discuss the subject on such grounds.

I am, Sir, your obedient servant,

Grosvenor-street, Feb. 14th, 1885. B. E. BRODHURST.

THE DYNAMITE EXPLOSION IN WESTMINSTER HALL.

To the Editor of THE LANCET.

SIR,—The professional interest attaching to the results of injury by explosives induces me to offer the following facts for your acceptance and publication. It is already well known how terrible were the injuries sustained by the two police constables Coles and Cox, at present under care in the Westminster Hospital—in the fearless exercise of their duty; and it cannot fail to excite the most general satisfaction that the lives of these brave men should have been spared.

My present purpose is to communicate some details respecting the serious injuries received by Mr. Edwin Green, the civil engineer, whose miraculous escape exceeds all natural expectation; indeed, the shattered condition of his hat and clothes can alone convey any adequate idea of the danger he survived.

At the request of the secretary of the Imperial Union Accident Assurance Company (in which office Mr. Green was insured) I visited him on the 30th ult., at his office in Abingdon-street, Westminster. Mr. Whitney, of Great Cumberland-street, had been in professional attendance since the date of the explosion; and, as the report with which I have been courteously favoured by this gentleman is so complete and descriptive, I may be permitted to include it *verbatim* as under:

"I was called to see Mr. Green, at 24, Abingdon-street, on the afternoon of Saturday, the 24th ult., whither he had been conveyed from Westminster Hall a few minutes previously, directly after the dynamite explosion. Prior to the explosion he was standing close to the spot where it took place, fell, and was taken up in a perfectly unconscious state. He was then removed to Abingdon-street. I found him with partially restored consciousness, but with his mind clouded and bewildered, lying on a bed, with little or no power of movement. There were at this time loss of vision, deafness, and bleeding from the right ear. The entire nervous system had evidently suffered a serious and severe concussion. The skin of the face had a curious appearance, not as if covered with fine dust, but of being absolutely dyed with dirt. Half the crown of the hat had been blown away by the explosion, and the clothes very much torn. On opening the front of the shirt the chest and epigastric region presented a large grazed and bruised surface marked with blood, as if a violent blow had been struck by some hard body of considerable size. In a few minutes the patient felt sick and vomited a large quantity of dark, clotted blood, mixed with portions of food. These vomits were repeated at intervals of a few minutes, still in considerable quantities, and then followed coughing and spitting of bright-red, frothy blood from the bronchial tubes and lungs. This hæmorrhage was a source of much anxiety, but, by a constant supply of ice and the administration of lead, was gradually subdued. It has not recurred. With the aid of a good constitution, unremitting care, and excellent nursing, he has made gradual and steady progress towards recovery. The disturbed functions are all steadily improving, the damaged visual and locomotive powers being last in the train of recovering organs. But vision, though improving, is yet wholly unfit for practical and professional purposes.

Feb. 5th, 1885. W. A. WHITNEY, M.R.C.S.

Mr. Whitney, in a subsequent letter, says: "I was forcibly struck with the apparent power of the lead in arresting the hæmorrhage; and I may add (which I did not mention in the report) that the administration of Easton's syrup from the date of Jan. 31st has been as obviously beneficial in helping to restore the locomotive power and to remove the paralysing effects of the nervous concussion."

In the last report, dated Feb. 14th, I was gratified to hear that "Mr. Green went home on Tuesday last, and is going on capitally."

Further comment by me is unnecessary.

I remain, Sir, yours faithfully,

J. HERBERT STOWERS, M.D.

Finsbury-circus, E.C., Feb. 1885.

THE CASE OF DR. DAVID BRADLEY.

To the Editor of THE LANCET.

SIR,—I have pleasure in informing you that I have been able to secure 166 signatures, of practitioners resident in Birmingham, to a memorial to be presented to the Home Secretary in favour of a reconsideration of the verdict in Dr. Bradley's case. At the Birmingham Midland Counties Branch of the British Medical Association held last Thursday, the following resolution was proposed by myself, seconded by Dr. E. B. Whitcombe, Superintendent of the Borough Asylum, and unanimously carried:—

"That this meeting having heard a statement of the case of Dr. David Bradley, recently convicted of felonious assault at the Leicester Assizes, desires to express its opinion that the case is eminently one in which a reconsideration of the verdict of the jury is demanded. This opinion is based upon a consideration of the following facts: First, that the complainant has been admittedly the subject of epileptic fits since childhood; secondly, that such persons are specially liable to be subject to erotic delusions during and after a seizure. It is therefore of the utmost importance that the corroborative evidence in such a case should be decisive, whereas in the case of Dr. Bradley it seems to be singularly defective." I am, Sir, yours truly,

The Crescent, Birmingham, Feb. 16th, 1885. LAWSON TAIT.

To the Editor of THE LANCET.

SIR,—Having been at Leicester Assizes in November last, and heard the whole of the evidence given in the above case, I shall be glad if you will allow me a small space in your journal to give you the result of some investigations I have made at the house on Whittington Moor, where the offence was alleged to have taken place. I went over there on the 14th inst., accompanied by Mr. Reginald Naylor, an architect of this town, who has kindly taken a plan of the rooms, which can be produced at any future investigation if necessary. The house is situated about the centre of a terrace of small dwellings, and has its front entrance opening *direct* into a parlour, which is 12 ft. square, and has a low bay window. This room was used by Dr. Bradley as a branch surgery, and here it is alleged the offence was committed. It is divided from the kitchen by a space of 2 ft. 8 in., containing the staircase. Between the parlour and kitchen are two badly fitting 1½ in. doors, with panels about ¾ in. thick. With both of these doors fastened we were able to hear conversation going on in the kitchen, and also the rattling of knives and forks whilst the inmates were at dinner. The parlour is separated from the cellar beneath by a plain one-inch boarded floor resting on joists, and conversation going on in the parlour could be distinctly heard in the cellar. During the whole of the time that Dr. Bradley and the prosecutrix were in the parlour together the woman who occupied the house was either in the kitchen or cellar, and yet she heard none of the screaming. The woman's husband was ill in bed in the room immediately over the parlour, where the voices of anyone in ordinary conversation can be distinctly heard, and yet he heard no screaming. Two women were about three yards from the front door, which was proved at the trial to be about one foot open, and yet *they heard no sound*. With the front door shut I was able to hear distinctly a child across the street playing with a shuttlecock and battledore. The architect admitted that he never saw such flimsily-built houses, and that any screaming must have been heard in the houses on either side, in the cellar below, and the bedroom above the parlour.

In conclusion, allow me to say that I know nothing of Dr. Bradley, and never saw him until he was in the dock.

I am, Sir, yours faithfully,

Friar Gate, Derby, Feb. 1885. GEORGE RICE, M.R.C.S.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

To the Editor of THE LANCET.

SIR,—I should be much obliged by your allowing me to correct an erroneous statement in THE LANCET of last week, in the report of the discussion on Mr. Davy's paper at the Medical and Chirurgical Society on "The Radical Cure of Club-foot" by osteotomy—i.e., the removal of a large wedge of bone from the tarsus. I am reported to have said that "Mr. Lund's operation"—removal of the astragalus—"interfered with the movements of the ankle-joint." What I did say was that Mr. Lund's operation dealt only with the ankle-joint, but free motion at this joint was obtained by removal of the astragalus; and at the present time, in the case operated upon by Mr. Lund ten years ago free motion still exists. Mr. Davy's operation dealt only with the transverse tarsal joint, leaving the ankle-joint, in severe cases, in a state of immobility with an elevated os calcis. Treatment should be directed against both these great centres of motion, which are of equal importance in the production and cure of the deformity. I am, Sir, yours obediently,

Henrietta-street, W., Feb. 17th, 1885. WM. ADAMS.

BIRMINGHAM.

(From our own Correspondent.)

THE GENERAL HOSPITAL.

THE annual meeting of the governors of this hospital was held on the 18th inst., when the committee presented their 105th annual report, with a statement of the receipts and expenditure for the year ending Dec. 31st, 1884. From the tables given it is seen that the large number of 47,560 patients were treated at the hospital in the year 1884, 3451 of these being in-patients; and of the total number 31,302 were free cases, attended to without tickets. The ordinary income of the year exceeded that of 1883 by £528. Of this excess £200 was due to an increased subscription list, a fact which, considering the general depression in trade, shows the high estimation in which the charity is held. The ordinary expenditure was £285 less than that of the last year, chiefly owing to a decrease in the number of in-patients; but the total expenditure has been increased by the outlay of £103 in the chapel, which greatly needed renovation and repair. The general account shows that the year ends with a deficiency of £3620, which the committee trust the liberality of the public will make good. Fitting eulogies were passed to the working staff of the hospital, and the prospects for the future were predicted as being highly encouraging.

THE LYING-IN CHARITY.

The annual meeting of this charity was held on the 12th inst., and was well attended. The committee's forty-second annual report pointed out that the work done had been eminently sound, and was progressing satisfactorily, the system of attending the patients exclusively at their own homes being followed by marked success. The number of patients attended during the year was 964, against 870 in the previous year, among whom there has been only one death, from puerperal convulsions, an extremely small percentage as compared with the Registrar-General's returns of the ordinary mortality in such patients. The number of children stillborn was 33, the number of deaths of children 47. Sixteen of them occurred during the ten days that the mothers were under the charge of the midwives, and the remaining 31 happened afterwards between the ten days and the date of the midwives' last call, thirty days after delivery. The financial condition of the charity was shown to be favourable. An important work is done by its means among the necessitous poor, the tickets being much sought and highly valued by the recipients. The figures show the enormous advantage gained by attendance upon the patients at their own homes, as contrasted with the former plan of aggregation in one building, thus confirming the opinion expressed by the best authorities of the lessened risk afforded by this system.

THE DENTAL HOSPITAL.

The twenty-fifth annual report of this useful institution has just been issued. The number of patients treated in the year was 7535, against 5672 in the preceding year, the increase being due mainly to the number of cases being sent from the General Hospital. This influx, though represented by numbers, does not carry a corresponding amount of funds with it, a matter of some regret to the authorities of the hospital. Anæsthetics were administered during the year in sixty-two cases, the greater number being nitrous oxide gas, which is necessarily a costly article for general use. An appeal is made for an increase in the number of subscribers, who yield the present income of £191, while the expenditure amounted to £134.

IRELAND.

(From our own Correspondent.)

PROPOSED AMALGAMATION OF SOME OF THE DUBLIN HOSPITALS.

THE deputation which lately had an interview with Earl Spencer were divided as regarded the advisability of amalgamation, some being in favour of the scheme and others indifferent or antagonistic. Of the £15,723 annually distributed, some valuable institutions receive a very small quota; for example, St. Mark's Ophthalmic Hospital but £100, Coombe Lying-in Hospital £200, and the Hospital for Incurables £250. The Westmoreland Lock Hospital does good service for its grant of £2000, also Steevens' Hospital with £1300, and the House of Industry Hospitals with £7400, while Cork-street Fever Hospital receives £2500. If the latter institution could be amalgamated with the Hardwicke Fever Hospital, it would be a desirable proceeding. Clinical instruction, which should be a *sine qua non* in institutions of this kind, is altogether absent in Cork-street Hospital; and further, its affairs are altogether managed by a lay committee, the majority of whom seldom, if ever, attend the meetings of the Board. As regards the proposal to form another medical school, the suggestion is perfectly absurd, there being at present too many institutions of the kind in Dublin, and adding another to the number would not be a desirable proceeding. What the Government will do it is difficult to say, but they appear to be strongly in favour of the amalgamation of some of the more important institutions which receive grants from Parliament.

ROYAL UNIVERSITY OF IRELAND.

The Senate have approved of certain changes in the courses in medicine, to come into operation next year, and have reappointed for another year the following examiners: In Medicine, Stephen M. MacSwiney; in Midwifery, John A. Byrne and H. M. Jones; in Materia Medica, F. B. Quinlan and J. Seton Reid; in Medical Jurisprudence, Edmund W. Davy and Michael McHugh. The Senate have also adopted the following resolutions: "That all graduates of the University who at present hold the diploma in Obstetrics be admitted to the degree of M.A.O. upon making application and complying with certain conditions." "That after the year 1885 credit will not be given to any candidate for Botany and Zoology at the first examination in Medicine upon the ground of having passed any Arts examination in which the subjects were comprised." The diploma in Sanitary Science has been conferred upon Dr. John Roche.

ARTERIAL ANOMALY AND MALPOSITION OF RIGHT KIDNEY.

In a subject brought into the Lædwich School of Medicine, Dublin, for dissection last week, a very rare arterial anomaly was found. The right renal artery came off at the bifurcation of the abdominal aorta into the common iliacs, and passing downwards was attached to the right kidney, which lay in the pelvis behind the bladder. The organ was also of one-third the normal size, while the artery supplying it was about the size of the profunda femoris. This malposition of the kidney is an extremely rare occurrence, and therefore worth recording.

NATIONAL ORTHOPÆDIC AND CHILDREN'S HOSPITAL, DUBLIN.

It is satisfactory to learn from the ninth annual report that this institution is now out of debt and has a small balance to its credit. This happy result was due, to a great extent, to a very successful bazaar held last December. The hospital has been amalgamated with the Pitt-street

institution, the first one of its kind established in the United Kingdom in 1821, exclusively for the treatment of children's diseases. It was founded by Sir Henry Marsh and Dr. Charles Johnson, and since then the staff has included Dr. Stokes, Sir P. Crampton, Mr. Cusack, Dr. William Moore, &c. Preliminary steps are being taken to secure plans and a suitable site for the building of a hospital for the ailments and deformities of children.

Dr. Levis, who contended that he was duly elected last November as medical officer of Skibbereen dispensary, and brought the matter into court, has this week, in an action against the guardians, established his right to the appointment.

Dublin, Feb. 17th.

PARIS.

(From our Paris Correspondent.)

CARDIAC HYPERTROPHY IN ADOLESCENTS.

PROFESSOR GERMAIN SÉE lately submitted a paper to the Academy of Sciences on Cardiac Hypertrophy occurring in Youth, or during the process of the growth of the body. He endeavours to make out that this hypertrophy is merely the result of growth, and not of any morbid influence, consisting as it does in a simple increase in the numerical strength of the primitive fibrillæ of the heart, or, in other words, in the hypernutrition or hypersarcosis of that organ, accompanied with dilatation. There is, moreover, no fatty or fibrous degeneration, nor are the coronary arteries sclerosed, as is the case with hypertrophy resulting from disease. It is, however, difficult to say whether the lesion in question consists in true hypertrophy or in simple dilatation of the heart, as it generally disappears with the cessation of growth of the other parts of the body. Professor Sée founded the subject of his thesis on eighty individuals, thirty of whom were youths aged from eight to sixteen years, and the others from sixteen to twenty-one, all being in other respects in a perfectly normal condition. In another class of cases—that is, in young recruits aged from seventeen to twenty, and who presented themselves for certificates for volunteer service—he found a great number who were the subjects of functional troubles or manifest lesions of the heart, as verified by auscultation and percussion. Professor Sée seemed to look upon this condition as almost normal in youth, and on that account did not consider that it incapacitated young men for military service. MM. Vulpian and Larrey, however, who had to report on the paper, did not take this view of the case, as they considered that hypertrophy of the heart, being an abnormal condition, is incompatible with the exigencies of military service. This opinion was emphasised by Baron Larrey from personal experience of many years, and he stated that, as it would be impossible to say whether the cardiac hypertrophy would or would not disappear at the cessation of the growth of the individual, as suggested by Professor Sée, he considered it advisable to reject the recruits who presented such a condition.

MM. CORNIL AND ROBIN.

According to a law recently passed in the French Parliament concerning the elections to the Senate or to the Chamber of Deputies, no member of either body can at the same time hold any other official appointment under Government. Professors Charles Robin and Cornil, who have been recently elected as Senators, will have to choose between the Senate and the respective chairs they now occupy at the Paris Faculty of Medicine, the former as Professor of Histology and the latter as Professor of Morbid Anatomy. It is anticipated that M. Robin will retire from his professorial chair; and it remains to be seen what will be the decision of M. Cornil, who is regarded as the favoured candidate for the Professorship of Histology.

MEDICAL HONOURS.

Among the list of the decorations of the Legion of Honour recently conferred by the President of the French Republic, I find the names of Dr. MacGavin and Dr. Walter Douglas Hogg, who were created Chevaliers of that Order for "exceptional," and I may add meritorious, services. Dr. MacGavin has been many years in practice in Paris, and Dr. Hogg is the son of the highly respected pharmacien of that name who has been established in this city for nearly thirty-five years.

Paris, Feb. 18th.

THE SERVICES.

THE EGYPTIAN EXPEDITION.

Classes for ambulance drill are to be formed amongst officers and men on board the transports.

Surgeon-General Oliver Barnett has been appointed Principal Medical Officer in command of the Medical Staff and Army Hospital Corps about to be despatched to Suakim.

Brigade Surgeon Hinde, Principal Medical Officer of the South-Eastern District at Dover, was to sail on Tuesday from Portsmouth.

Quartermaster F. Thompson, Medical Staff, is ordered to Aldershot to prepare for embarkation to Suakim.

Surgeon-Major Evatt, M.D., Medical Officer to the Royal Military Academy, Woolwich, has been ordered to hold himself in readiness to sail for Egypt.

There is no foundation for the report that the Government has sent a circular to the leading medical schools of the country asking students to volunteer as dressers for the Soudan campaign.

Drs. Reed and Alexander, with a detachment of the Army Hospital Corps, on the 18th took up their berths in the *Ganges*, which has been chartered for service as a hospital ship.

The medical officers finally appointed to the 3rd Battalion of Guards are Surgeon-Major Lawrence, Surgeon Fenn, and Quartermaster Tedding.

Orders have been received at Aldershot for the concentration at that station of another detachment of the Medical Staff Corps for service in the Soudan.

On the 17th inst. the 1st Bearer Company, the 1st and 2nd Field Hospitals of the Medical Staff Corps, besides details of the Commissariat and Transport Corps, under orders for the Soudan, proceeded by special trains from Aldershot to Southampton, where they embarked in the steamer *Arab* for conveyance to Suakim.

Colonel Loyd-Lindsay, Chairman of the National Society for Aid to the Sick and Wounded in War, states that the Society has again been in communication with Lord Wolseley and with the authorities at home, and it is now equipping an expedition which will go to Suakim under the charge of Mr. V. Barrington Kennett as its representative in that district, with a staff of surgeons and a liberal supply of comforts and medical appliances. The intention is to form stations for the relief of sick and wounded men along the lines of communications. In this the Society is acting in entire accordance with and under the advice of Dr. Crawford, the Director-General of the Army Medical Department.

WAR OFFICE.—Royal Horse Guards: Surgeon James Stevenson Forrester, from the Medical Staff, to be Surgeon, vice W. Maunsell-Collins, M.D., retired.

INDIA OFFICE.—The Queen has approved of the retirement from the service of the following officers of Her Majesty's Indian Military Forces:—Brigade Surgeon William Payton Partridge, of the Bombay Army; Brigade Surgeon William Henry Kirton, of the Bengal Army.

The following officers are granted a step of honorary rank on retirement:—Deputy Surgeon-General John Edward Tuson, M.D., of the Bengal Army, to be Surgeon-General; Surgeon-Major Rivers Mantell, of the Bengal Army, to be Brigade Surgeon.

ADMIRALTY.—Fleet Surgeon Adam Brunton Messer, M.D., has been promoted to the rank of Deputy Inspector-General of Hospitals and Fleets in Her Majesty's Fleet. The following appointments have been made:—Staff Surgeon Richard A. Mowll, M.D., to the *Nankin;* Surgeon Herbert W. A. Burke, to the *Excellent;* Fleet Surgeon William G. Ridings, to the Royal Marine Artillery, Portsmouth.

RIFLE VOLUNTEERS.—2nd Volunteer Battalion, the Queen's Own (Royal West Kent Regiment): Honorary Assistant-Surgeon Robert Nathaniel Mitchell, M.D., resigns his commission; also is permitted to retain his rank, and to continue to wear the uniform of the battalion on his retirement.—2nd Volunteer Battalion, the Lancashire Fusiliers: Lieutenant William Pooley is appointed Acting Surgeon.—12th Middlesex (Civil Service): Walter Robert Tytheridge, Gent., to be Acting Surgeon.—1st Volunteer Battalion, the Queen's (Royal West Surrey Regiment): Acting Surgeon Charles William Philpot, M.D., to be Surgeon.

LADY LEE has given the sum of £200 to the funds of the Maidenhead Cottage Hospital.

Medical News.

COLLEGE OF PHYSICIANS IN IRELAND.—At the February examinations the following obtained the licences in Medicine and Midwifery of the College:—

MEDICINE.—Berkeley Joseph Acheson, Francis Forster Brady, George Arthur Hawkins-Ambler, Julian Sewell Hayes, John Keenan, Denis Patrick Kenna, Francis Ignatius Maunsell, Sampson Roch, John Thomas Walsh.

MIDWIFERY.—W. J. Cawden, H. S. Fairbank, Lawrence B. P. Fernandez, George Arthur Hawkins-Ambler, John Keenan, D. P. Kenna, Francis Ignatius Maunsell.

The undermentioned were admitted Members:—

Thomas Vesey Bell. | Michael Joseph Yourrell.

UNIVERSITY OF DUBLIN.—At a meeting of the Senate held this week the following degrees were conferred:—

BACHELOR IN SURGERY.—John Blacker Buchanan, Henry Augustus Ellis, Samuel Handy Halahan, William Lacy Hickey, Joseph Ewing Miller, James John O'Donnell, Daniel R. O'Sullivan, George Raymond, William Richardson Rice, Rowland Hill Scovell, Walter John Slaughter, John James Carl Watson.

LICENTIATE IN SURGERY.—Joseph Vincent Manning.

BACHELOR IN MEDICINE.—Edward J. Farmer, Samuel Handy Hallahan, Robert Kerr Johnston, Robert Travers, Lewis Arthur Henry Mecke, Joseph Ewing Miller, Robert John Montgomery, James John O'Donnell, George Raymond, Walter John Slaughter.

DOCTOR IN MEDICINE.—Alexander James Boyd, Richard Alfred Lett, Arthur Henry Mecke, Victor Edwin Smith, Charles Herbert Thompson, William McDowell Aikin Wright (stip. cond.).

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on the 12th inst.:—

MacGillycuddy, Niell, University College.
Maude, Arthur, St. Bartholomew's Hospital.

THE Society for the Total Suppression of the Sunday Sale of Liquor has just held its annual meeting in Manchester. The income had amounted to £2840 during the year.

MEDICAL MAGISTRATE.—Mr. G. Booth, M.R.C.S., has been placed on the Commission of the Peace for the borough of Chesterfield.

AT a meeting held at Hastings on the 17th inst., to receive the annual report of the Local Sanitary Aid Association, the committee reported the continued progress of the organisation.

ROYAL COLLEGE OF SURGEONS.—Professor Treves will commence his course of lectures on the Anatomy of the Peritoneum and Intestinal Canal in Man on Monday, the 23rd inst., in the theatre of the College.

HOSPITAL SATURDAY FUND.—Mr. Samuel Morley, M.P., has been unanimously re-elected President of this fund for the ensuing year; and the names of the Rev. C. H. Spurgeon and Mr. B. Lucraft have been added to the list of Vice-Presidents.

PRESENTATION.—Dr. J. W. Mathews, of Kimberley, has been presented by the Mussulmans of that place with a silver cup and an address, as a mark of respect and admiration for his outspoken defence of the rights and liberties of Mahomedans during the late epidemic.

PURIFICATION OF TOWN SEWAGE.—A deputation from the North of France, who are now in England with the object of ascertaining the best mode of treating town sewage and the purification of rivers, visited on the 16th inst. the sewage works at Mode Wheel belonging to the Corporation of Salford, to which the visitors gave unqualified praise. The deputation afterwards proceeded to Glasgow.

ST. JOHN AMBULANCE ASSOCIATION.—Rooms at the Mansion House have been placed at the disposal of the City and Port of London executive of the St. John Ambulance Association, to hold afternoon classes for the benefit of *employées* in offices and business establishments. Two of the five classes meeting at Lady Brassey's house have been examined by Mr. R. Bruce, M.B., and Deputy Inspector-General M. Coates, R.N.

ROYAL FREE HOSPITAL.—At the fifty-seventh annual general court of the governors of this hospital, held on the 12th inst., it was stated that the receipts from all sources during the past year had amounted to £15,772, and the expenditure to £11,590, there being a balance of about £3000 to the credit of the institution. During the year 22,736 persons were treated, of which number 20,816 were out-patients. The daily average of in-patients in the wards was 136.

THE GUILD OF ST. LUKE THE PHYSICIAN.—At a large gathering of the members of this Society, held on the 18th inst. at the rooms of the Medical Society, Chandos-street, Dr. Wynn Westcott, the Deputy Coroner for Central Middlesex, delivered, by request, a lecture on "Suicide, its Causes and the best Means of Prevention." The lecture was well received, and will be published in the monthly periodical of the Guild. Mr. Cowell, F.R.C.S., of the Westminster Hospital, was the chairman of the meeting.

SOUTH DEVON AND EAST CORNWALL HOSPITAL.—The annual general meeting in connexion with this institution was held on the 3rd inst., when the remainder of the new building, part of which was formally opened some time ago, was declared complete. The new hospital is built on the pavilion system, and is in most respects modelled after the Edinburgh Infirmary. Accommodation is afforded for 120 patients, with an average of 1700 cubic feet of space for each. The receipts during the past year amounted to £3775, and the expenditure to £3675. The number of in-patients was 750, and of out-patients 1988.

NORTH-WESTERN ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.—At a recent meeting of this Association the discussion on Dr. Hope's paper on Infantile Diarrhœa, read at the previous meeting, was continued by Drs. Vacher, Samelson, Barr, Ashworth, Kenyon, and Mr. Corbett. Dr. Kenyon read some notes on the subject of revaccination, and a memorial to the Local Government Board, prepared by Dr. Vacher, was adopted. Mr. Fred. R. Hawxby, B.A., architect, afterwards described a plan which he had adopted of heating and ventilating houses, the principal features of the scheme being those advocated by Drs. Drysdale and Hayward of Liverpool—viz., the admission to the house of an ample supply of fresh air, and the extraction of the vitiated air by means of the waste heat of the kitchen fire. The arrangement has been already applied by Mr. Hawxby in a house erected by himself, and is reported to work satisfactorily.

MERCER'S HOSPITAL, DUBLIN.—At a recent meeting of the past and present students of this hospital, resolutions to the following effect were carried: 1. That the recent alterations in the working of the hospital are calculated to interfere greatly with the surgical practice and teaching of the institution, and that they are unnecessary. 2. That the post of house-surgeon being an annual one, and open to all students of the hospital qualified to fill it, the action of the medical board in filling the post for the ensuing year without notifying the vacancy to the students by advertisements or otherwise is most arbitrary and unfair. 3. That the system of not admitting patients unless upon the joint order of two lay or two medical governors is absurd. 4. That it is absolutely necessary that some steps be taken by the board to enable the medical and surgical staff to give proper clinical lectures. 5. That should any reduction in the number of admissions to the hospital be made, such reduction should in no way curtail the right of the senior surgeon for the time being to a larger proportion of beds than any other member of the staff.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

ARBUCKLE, HUGH WIGHT, M.D.Aber., L.F.P.S.Glas., L.R.C.P.Ed., has been appointed Medical Officer for the Stamford District and Workhouse, Thorne Union.

BLUMER, W. PERCY, F.R.C.S.E., has been appointed Honorary Surgeon to the Sunderland and North Durham Eye Infirmary, vice E. Allan Maling, M.R.C.S., J.P., resigned.

GELSTON, JOHN SEYMOUR, L.K.Q.C.P.I., L.R.C.S.I., has been appointed House-Surgeon to the Doncaster Infirmary and Dispensary, vice Marshall, resigned.

GREEN, C. D., M.B., M.R.C.S., L.R.C.P., has been appointed House-Surgeon to St. Thomas's Hospital.

HARRIS, THOMAS, M.D.Lond., has been appointed Assistant Lecturer and Demonstrator in Pathology at the Owens College, Manchester, vice Robert Maguire, M.D.Lond., M.R.C.P., resigned.

HILL, G. W., B.Sc., L.S.A.Lond., has been appointed Medical Officer for the St. Just District of the Truro Union, vice Harden, deceased.

HUBBARD, FREDERICK EDMUND, L.R.C.P.Lond., M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the Fifth District of the Depwade Union, vice Rose.

HULL, WALTER, M.B., M.R.C.S., L.R.C.P., L.S.A.Lond., has been appointed House-Surgeon to St. Thomas's Hospital.

JOHNSTON, G. D., M.R.C.S., L.R.C.P., has been appointed Resident Accoucheur to St. Thomas's Hospital.

LANKESTER, H. H., M.R.C.S., L.S.A.Lond., has been reappointed Non-resident House-Physician to St. Thomas's Hospital.

LEE, CHARLES G., M.R.C.S., L.R.C.P.Lond., has been appointed Honorary Surgeon to the Liverpool Eye and Ear Infirmary, vice T. Shadford Walker, M.R.C.S., appointed Honorary Consulting Surgeon.

MACKENZIE, H. W. G., M.A., M.B., M.R.C.S., has been appointed Resident House-Physician to St. Thomas's Hospital.

MARRINER, W. H. LISTER, M.B., M.R.C.S., L.S.A.Lond., has been reappointed Clinical Assistant in the Department for Diseases of the Throat at St. Thomas's Hospital.

MIDDLETON, LUCAS ALFRED, L.K.Q.C.P.I., L.R.C.S.I., has been appointed Medical Officer for the Harbourne District of the King's Norton Union, vice Smith.

PLUMMAN, S., M.R.C.S., L.S.A.Lond., has been reappointed Clinical Assistant in the Departments for Diseases of the Skin and Ear at St. Thomas's Hospital.

PRIEST, J. DAMER, M.R.C.S. & L.S.A.Lond., has been appointed Acting Surgeon to the War Department Royal Gunpowder Manufactory, Waltham Abbey. Also Certifying Factory Surgeon, and Surgeon to the N Division of the Metropolitan Police.

PULLAN, H. W., L.F.P.S.Glas., M.R.C.S., has been appointed Medical Officer for the Belton District of the Thorne Union.

RELTON, BERNARD, M.R.C.S., L.S.A.Lond., has been appointed Assistant House-Surgeon to St. Thomas's Hospital.

ROBINSON, H. B., M.R.C.S., L.R.C.P., has been appointed Resident House-Physician to St. Thomas's Hospital.

SAKURAI, Y., M.R.C.S., L.R.C.P., has been appointed Assistant House-Surgeon to St. Thomas's Hospital.

STEWART, JAMES PICKERING, M.B., C.M.Glas., has been appointed Medical Officer for the Gosberton District of the Spalding Union, vice Swan.

WHITE, SINCLAIR, M.D., M.Ch.Q.U.I., F.R.C.S.Eng., has been appointed Medical Officer of Health for the Sheffield Urban Sanitary District, vice Whitgreave.

WILLIAMS, R. M., M.R.C.S. L.R.C.P., has been appointed Assistant House-Physician to St. Thomas's Hospital.

Births, Marriages, and Deaths.

BIRTHS.

FRASER.—On the 14th inst., at Melville-street, Edinburgh, the wife of Dr. Thomas R. Fraser, F.R.S., Professor of Materia Medica in the University of Edinburgh, of a son.

SMYTH.—On the 12th inst., at Holly Lodge, Brockley, S.E., the wife of Fordyce Smyth, L.R.C.P.Ed., F.R.C.S.Ed., of a son (stillborn).

STUART.—On the 13th inst., at Poona, the wife of Surgeon Alex. K. Stuart, of H.M.'s Indian Medical Service, of a son.

TAYLOR.—On the 10th inst., at The Cedars, Kenninghall, Norfolk, the wife of J. H. Wilson, M.R.C.S., of a son.

WRIGHT.—On the 15th inst., the wife of Francis Jas. Wright, M.D., of Northumberland House, Finsbury-park, N., of a son.

MARRIAGES.

BOOSEY—GWATKIN.—On the 12th inst., at Holy Trinity Church, Twickenham, J. B. Bradbury, M.D., of Cambridge, to Jane, elder daughter of the late Rev. R. Gwatkin, B.D., formerly Fellow and Tutor of St. John's College, Cambridge, and Vicar of Barrow-on-Soar, Leicestershire.

BOYS—BEAUMONT.—On the 12th inst., at Chudleigh, Devon, by the Rev. Walter Moyle, M.A., cousin of the bride, assisted by the Rev. Theophilus Bennett, M.A., S. E. Carter, Esq., M.D.Lond., to Edith Caroline, youngest daughter of the late Col. Wm. Beaumont, of Her Majesty's Indian Army, and of Fairfield, Chudleigh, Devon.

WIGNALL—HIGGINBOTHAM.—On the 11th inst., at St. Mary's Church, Barnfield, by the Rev. John McWhinnie, Staff Surgeon R.N., to Harriet, widow of the late Thos. Higginbotham, of Barnfield, Alderley Edge, Cheshire.

WILLIS—BROOKS.—On the 14th inst., at St. Matthew's, Denmark-hill, by the Rev. C. E. Jones, William Mill, M.R.C.S., L.R.C.P., of Halford, Warwickshire, to Ella Frederica, youngest daughter of the late Wm. Brooks, Denmark-hill, S.E.

WILSON—COOKE.—On the 17th inst., at St. Andrew's, Newcastle-on-Tyne, A. Campbell Munro, M.B., D.Sc., South Shields, to Emily Isabel, daughter of the late Richard Cooke, Woodford, Essex.

DEATHS.

FRANKLIN.—On the 12th inst., after two days' illness, at Liverpool-road, Hy. Franklin, L.R.C.P.Ed., late of St. John's-street, Clerkenwell.

GOUGH.—On the 16th inst., at Epsom, Sergeant D. Gough, in his 67th year, for twenty-seven years drill-master at the Royal Medical College, Epsom.

LEWIS.—On the 8th inst., at Davos, Switzerland, George Stephens Lewis, Surgeon Army Medical Staff, late of Alexandria, Egypt.

MARTIN.—On the 13th inst., at Alexander-square, South Kensington, James Johnstone Martin, Fleet Surgeon R.N., aged 63.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Medical Diary for the ensuing Week.

Monday, February 23.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M. each day, and at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M. each day, and at the same hour.

ST. MARK'S HOSPITAL.—Operations, 2 P.M., and on Tuesdays at the same hour.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

MEDICAL SOCIETY OF LONDON.—Dr. Felix Semon: Electric Illumination of different Cavities of the Human Body (mouth, pharynx, larynx, nose, ear, vagina, rectum), Faradisation, Galvano-Cauterisation, and Electrolysis, by means of Pocket Accumulators chargeable at home.—Mr. Hurry Fenwick: Cocaine in Vesico-urethral Practice.

Tuesday, February 24.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 P.M., and Thursdays at 2 P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M., and on Fridays at 2 P.M.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M., and on Saturday at the same hour.

ROYAL INSTITUTION.—3 P.M. Prof. S. Colvin: Museums and National Education.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—8.30 P.M. Dr. Ormerod: Hereditary Locomotor Ataxy (cases will be exhibited to illustrate Dr. Ormerod's paper).—Dr. Samuel West: Fatal Hæmoptysis, the statistics of the last fifteen years of the Chest Hospital, Victoria-park, with Remarks upon Profuse Non-fatal Hæmoptysis.

Wednesday, February 25.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M., and on Saturday at the same hour.—Ophthalmic Operations on Tuesdays and Thursdays at 1.30 P.M.

ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Skin Department: 9.30 A.M., on Tuesdays and Fridays.

ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M., and on Saturday at the same hour.

LONDON HOSPITAL.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.

GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M., and on Saturday at the same hour. Skin Department: 1.45 P.M., and on Saturday at 9.15 A.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.

HUNTERIAN SOCIETY.—Dr. Pye-Smith: Presidential Address.—Dr. Stephen Mackenzie: The Connexion between Erythema Nodosum and Rheumatism.

Thursday, February 26.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Surgical Consultations, 1.30 P.M.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and on Friday at the same hour.

NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

ROYAL COLLEGE OF PHYSICIANS.—5 P.M. Dr. William Osler: Endocarditis (Gulstonian Lecture).

ROYAL INSTITUTION.—3 P.M. Prof. Dewar: The New Chemistry.

Friday, February 27.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1.30 P.M.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.

QUEKETT MICROSCOPICAL CLUB.—8 P.M. Mr. Buffham: The Conjugation of Rhabdonema Arcuatum (Kutz).

CLINICAL SOCIETY OF LONDON.—8.30 P.M. Dr. Hughes-Bennett: A Case of Locomotor Ataxy without any Disease of the Posterior Columns of the Spinal Cord.—Dr. Seymour Taylor: A Case of Arrested Rickets.—Mr. Charters Symonds: A Case of Nephro-lithotomy.—Mr. Henry Morris: A Case of Nephro-lithotomy.—Dr. Hadden: A Case of Obliterative Disease of Vessels (living specimen).

ROYAL INSTITUTION.—9 P.M. Prof. E. Ray Lankester: A Marine Biological Laboratory.

Saturday, February 28.

KING'S COLLEGE HOSPITAL.—Operations, 1 P.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M.

ROYAL INSTITUTION.—3 P.M. Mr. C. Armbruster: Richard Wagner.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe, or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

THE INDEX MEDICUS DISCONTINUED.

WE regret to observe that a notice accompanies the annual index which completes the sixth volume of the Index Medicus, informing subscribers to that publication that it will with that issue cease to be published. The late Mr. Leypoldt, the publisher, regarded the undertaking with particular favour; and his successors, who are managing his estate and business enterprise, have made strenuous, but futile, efforts to secure the subscriptions necessary to place the Index Medicus on a self-supporting basis.

Mr. W. Dobson (Leeds).—The announcement appeared in our last number, page 299.

KING AND QUEEN'S COLLEGE OF PHYSICIANS, IRELAND.

To the Editor of THE LANCET.

SIR,—In these days of medical reform it has been a matter of surprise to me that it has not been suggested to alter the name of the King and Queen's College of Physicians to that of Royal College of Physicians. There are many reasons in favour of such an alteration, and none that I know of against such a change. For the former the following arguments may be advanced:—1. The public recognise the letters "L.R.C.P.," understand their value, and know what they represent. The letters "L.K.Q.C.P.I." to most outside the profession are utterly unintelligible. 2. The advantages of simplification and uniformity in the designation of medical qualifications. 3. The boon conferred on all who hold the diploma of the College in being enabled to place letters after their names that will represent something to the public beyond hieroglyphics. As a case in point, a medical friend (a L.K.Q.C.P.I.) informs me that he is going in for another medical qualification, as he considers the ambiguity of these letters detrimental. For the same reason I have recently written to the Royal College of Physicians, London, with a view of passing the necessary examination to obtain their licence, though I am a M.K.Q.C.P.I., feeling the same might be an impediment should I enter into civil life either at home or abroad.

I appeal, Sir, to you, that through the aid of your powerful journal this subject may have due consideration, as I feel sure those who hold the diploma of the College must see the advisability of such a change.

I am, Sir, yours faithfully,

Feb. 16th, 1884. SURGEON, R.N.

Mr. Alfred Drysdale (Mentone) is thanked; but the publication of the letter would hardly be agreeable, we think, to the surviving relatives of the deceased gentleman.

Subscriber could not certify. He might express an opinion.

EFFECTS OF EXCESSIVE CIGARETTE SMOKING.

To the Editor of THE LANCET.

SIR,—I have a patient, aged forty, subject to chronic pharyngitis, kept up by excessive cigarette smoking. His general health is good, and all the symptoms are easily recognisable, except one which I have never seen myself nor heard described by others—viz., that once, and sometimes twice, a day, without any special effort, he expectorates a vermiform substance, about a quarter of an inch long and one-sixteenth of an inch thick, tough in substance, and of a nauseous taste, though not odorous. It appears to me like a combination of mucous and sebaceous matters secreted in one of the minor conduits and moulded by the latter into its shape. Can you or any of your readers enlighten me on a subject of which I am fain to confess my ignorance?

I am, Sir, your obedient servant,

London, Feb. 16th, 1885. M.D.

Mr. A. Glover Williams will get the name of the secretary and other particulars by inquiring of the Charity Organisation Society.

"ALL FOR THE SAKE OF A DOCTOR."

THE *Kentish Independent* comments on Mr. Spear's report to the Local Government Board in a leading article with the above heading. Our contemporary thinks that Woolwich is to be congratulated on its unique position amongst English towns in not being compelled to appoint a medical officer of health. He even claims to echo the voice of local medical opinion, for he says: "The authorities ..... have a system, which they think a good one, by which all the practitioners of the district form a sort of volunteer corps of medical officers, such practitioners, with few exceptions, preferring this to the other alternative of a parish doctor poking his nose into their cases, and possibly meddling with their patients." We are quite unable to understand how the local practitioners can be said to form a "volunteer corps of medical officers," nor can we learn that they are parties to such an arrangement. And as the number of civilian practitioners is about thirty, to which must be added ten military surgeons, the division of responsibility among such a number would leave but little to be borne by any individual member. It is true that a half-crown fee is paid by the local board to medical men for notifying a case of infectious disease. Surely, the *Kentish Independent* does not suppose that notification is the duty of a medical officer of health. His duty is, amongst other things, to deal with infectious disease when it has been notified. This function is now performed by the inspector of nuisances, who is an engineer, and his assistant; and though Mr. Spear very properly praises the labours of these officials, he points out forcibly, though the *Kentish Independent* cannot agree with him, that it is impossible for the sanitary affairs of a town to be satisfactorily conducted in the absence of a responsible skilled medical adviser.

Consultants' Mileage Fee.—We do not think a uniform tariff in consultation fees practicable.

CONCUSSION, DISLOCATION, OR MERELY A FAINT—WHICH WAS IT?

To the Editor of THE LANCET.

SIR,—With reference to the interesting case of displacement and fracture of the axis recorded in your issue of the 14th inst., I beg to submit an extract from a very rare book—"A Journal or Historical Account of the Life, Travels, &c., of George Fox," London, 1694, vol. ii., pp. 151-2, which appears to me to bear upon it, and which you will, I trust, publish, if your space will so allow. Describing a visit he (Fox) paid to Shrewsbury, he says that one of his companions, named John Day, "being to try an horse, got upon his back; and the horse fell a running and cast him upon his head, and brake his neck, as the people said. They that were near him took him up dead, and ..... laid him on a tree. I got to him as soon as I could, and feeling on him concluded he was dead. And as I stood by him, pitying him and his family, I took hold of his hair, and his head turned any way, his neck was so limber. Whereupon, throwing away my stick and my gloves, I took his head in both my hands, and setting my knees against the tree I raised his head and perceived there was nothing out or broken that way. Then I put one hand under his chin and the other behind his head, and raised his head two or three times *with all my strength, and brought it in.* I soon perceived his neck began to grow stiff again, and then he began to rattle in the throat, and quickly after to breathe. The people were amazed, but I bid them ..... carry him into the house. They did so, and set him by the fire, and afterwards put him to bed. After he had been in the house awhile he began to speak, but did not know where he had been. The next day we passed away (and he with us, pretty well) about sixteen miles, ... and many hundred miles did he travel with me after this.' If success be a test of treatment, a more judicious one could scarcely have been employed in this instance. I think it quite possible that there was a displacement here of one or other of the upper cervical vertebræ, and the words I have italicised would seem to imply as much. But of this your readers are as competent to judge as I am, and I merely reproduce the extract as a curiosity in its way, and in the connexion just referred to.

I am, Sir, yours obediently,

Feb. 17th, 1885. FRANCIS.

Mr. F. Peter Smith.—The papers sent are very bad; but we cannot prosecute the subject nor the rascals who thrive on the ignorance of their dupes.

Dr. J. Chapman (Paris).—We cannot undertake to return MSS. not used.

"PRURITUS VULVÆ."

To the Editor of THE LANCET.

SIR,—In your issue of the 24th ult. "M.D." asks for suggestions regarding the treatment of pruritus vulvæ, the various remedies employed by him not having succeeded. I would suggest an examination of the urine for sugar, diabetes being so frequently accompanied by pruritus—in fact, it is occasionally the only symptom complained of. If sugar be found, I would recommend "M.D." to administer half-grain of codeia three times a day (with the usual limitations regarding diet), and, I think, in a short time the pruritus will be greatly relieved. It will be interesting to know the result of treatment in the case.

I am, Sir, yours faithfully,

Leominster, Feb. 16th, 1885. RICHARD WATTS WHITE.

PANFILO CUSTALDI AND THE ART OF PRINTING.

A COLLECTION of interesting documents relating to the life of Panfilo Custaldi, for whom the honour of the invention of printing has been claimed by patriotic Italians, have recently been discovered, and will, we understand, shortly be published in the *Archivio Storico per Trieste, l'Istria, ed il Trentino*. It is not stated that these documents give any support to the claim above alluded to; but it appears that Custaldi, who was a physician practising in Capo d'Istria, was already practising the art of printing with movable types as early as 1461, in partnership with two other residents in the same town.

Trocar.—If the patient was in a critical state when seen by our correspondent, it would not be right to expose him to a four hours' drive while suffering from strangulated hernia. If operative interference was not immediately necessary, "Trocar" was carrying out the intentions of the Local Government Board, and the wishes of most boards of guardians, by sending the patient to be operated upon to the nearest hospital or infirmary.

M.R.C.S.—1. No. 1, Old Serjeants' Inn, Chancery-lane, W.C.—2. No.

"CASCARA SAGRADA."

To the Editor of THE LANCET.

SIR,—We notice in your issue of the 14th inst. a correspondent, "A. G. C.," asks where to procure a really trustworthy preparation of the cascara sagrada. We beg to say that the experiments made by medical practitioners in this country with Messrs. Parke, Davis, and Co.'s preparation, for which we are the agents, have been most successful; and we shall be very pleased to forward samples to "A. G. C." and any other medical man who may wish to try it.—Yours faithfully,

BURGOYNE, BURBIDGES, CYRIAX, AND FARRIES.

Coleman-street, E.C., Feb. 16th, 1885.

To the Editor of THE LANCET.

SIR,—"A. G. C." should try the fluid extract made by Messrs. Parke, Davis, and Co., or by Messrs. Ferris and Co. In my hands they have proved most effectual. I can also speak favourably of the pills made by Messrs. W. H. Schieffelin and Co., each of which contains two grains of the solid extract. I am, Sir, yours truly,

Peterborough, Feb. 14th, 1885. W. EASBY, M.D.

To the Editor of THE LANCET.

SIR,—In reference to the inquiry by "A. G. C." in your current issue, I would beg to observe that the extract of cascara sagrada was prescribed for me recently in the form of a pill (in four-grain doses), combined with nux vomica, belladonna, and gentian, by my friend Dr. Cullimore of Welbeck-street, W., for obstinate constipation due to sluggish action of the liver, with marked benefit. I found that one four-grain dose twice a day for a few days, and afterwards once a day, produced the desired result. I would add, as desired by your correspondent, that the medicine was made up by Messrs. Twinberrow and Son of Wigmore-street, Cavendish-square. I am, Sir, yours truly,

Feb. 16th, 1885. JOHN LUCAS, M.D.

*** Other communications received by us would seem to show that there is no difficulty in obtaining trustworthy samples of the cascara.—ED. L.

Mr. Edward Wheeler.—We did not mean to affirm that Jenner appreciated the necessity for revaccination as we now understand it; but that the second subjection to the operation by the small-pox hospital nurses, with its magnificent results, are, in a sense, the confirmation and completion of Jenner's discovery of vaccination. What view does Mr. Wheeler take of the immunity enjoyed by the officials of the small-pox hospitals?

THE ADMISSION OF PATIENTS SUFFERING FROM FITS TO ASYLUMS FOR IDIOTS.

To the Editor of THE LANCET.

SIR,—I notice in one of your answers to correspondents in THE LANCET of last week you say: "Patients subject to fits are, we believe, ineligible for admission to idiot asylums." Having been attached to the Earlswood Asylum some years ago, I beg to inform you that the majority of the patients in that institution are subject to fits, and I believe it is the same at other idiot asylums.—Yours faithfully,

Brentwood, Feb. 16th, 1885. J. R. WHITE, M.B.

*** The published prospectuses of the majority of idiot asylums do not bear out the last statement of our correspondent's letter.—ED. L.

THE ARABS WOUNDED IN THE SOUDAN.

To the Editor of THE LANCET.

SIR,—May I ask through the medium of your valuable journal whether any provision is made for the surgical and medical treatment of the poor Arabs wounded in the battles in the Soudan? It is to be trusted that they receive the same humane treatment as our own wounded soldiers, and are not left to die unaided on the ground which they so bravely defend. I am, Sir, yours obediently,

Leeds, Feb. 14th, 1885. H. A. ALLBUTT, M.R.C.P.

MEDICAL ETIQUETTE AT CRIEFF.

A CORRESPONDENCE has been sent us for publication by Dr. Gairdner, jun., of Crieff, between himself and Dr. Alex. Thom, jun., beginning as far back as January, 1881, and ending in February, 1885. It will be readily understood that we have seldom room for such a correspondence in THE LANCET. We certainly have not at present. There is another objection to its publication in the fact that it is incomplete. Dr. Thom chose, rightly or wrongly, to answer Dr. Gairdner by letter, defending himself by saying that he had also answered verbally. It is difficult to express a judgment on an incomplete correspondence. We regret the difference between Dr. Gairdner and Dr. Thom, the more so as it seems to us that nothing could be in better taste and form than the letter from Dr. Thom to Dr. Gairdner with which the correspondence opens, accepting, but only reluctantly, a half fee sent him by Dr. Gairdner for attending a case in his absence. His action in other cases is not, in appearance, satisfactory: as when he visits as a friend a case in which his father had met Dr. Gairdner in consultation; and when he visits after delivery an obstetric case of Dr. Gairdner's, which he attended in an emergency arising from the latter's unavoidable absence in the country. But then we have not his version of the facts, and hesitate to pronounce judgment without it. In one case we are not so sure that Dr. Gairdner is quite right—where he declines a consultation with Dr. Thom on the doubtful ground *that the patient had had other consultations*. But the matters in dispute seem to us such as should admit of easy adjustment.

M.D. wishes to know if magnetism or galvanism is effectual in hypochondria with a tendency to hysteria?

CASE OF ATHETOSIS.

To the Editor of THE LANCET.

SIR,—On Nov. 5th, 1884, John H——, a native of Bremen, was sent to me by a fellow practitioner for treatment. On examination, I found him suffering from that rare and peculiar nervous affection called by Hammond "athetosis." Unfortunately, I was able to keep the patient under observation for only a short time, as he was a vagrant, and left the city after his second visit to my office. He was a German, healthy, well nourished, and, according to his statement, strictly temperate. There was no history of syphilis, nor was there any evidence of struma or protean disease of any kind whatever. The patient said he had been suddenly seized with a violent pain in the right forearm, with convulsive movements of the fingers of the right hand, while walking, six weeks before he came to me. The pain in the arm and the movements of the fingers had continued without intermission. He said that his companions had told him the convulsive movements of the fingers continued during sleep. There were continual contractions and partial extensions of all the fingers of the hand affected. The muscles of the forearm were hard and rigid, and seemed not to relax for a moment during the whole time he was under my observation. The patient was unable to close his hand, having no control whatever over the flexor muscles. He had slight control over the extensors, being able by exerting all his power to extend the fingers; they were, however, immediately flexed again. The movements of the fingers were of a peculiar writhing and twisting character. The patient complained of considerable pain in the arm up to the elbow. There was slight hyperæsthesia in the affected forearm and hand, and an increase in temperature. In all other parts of the body sensibility to touch and temperature were normal. The involuntary contractions of the fingers came on hurriedly, violently, and with great force. The contractions were somewhat paroxysmal, with no increase of pain in proportion to the violence of the contractions. The patient was unable for a single instant to arrest the movements of the fingers and fix them in any one position. I gave him as a *placebo* a hypodermic injection of morphia, and directed him to call again on the following morning. He came, but for some reason would allow no further examination, and left for I know not where.

I have seen but one other instance of this peculiar affection, and that was a mulatto woman brought before the Tri-State Medical Association at Henderson, Ky., in 1878, by Dr. Dixon, if I am not mistaken. I have endeavoured to give this man's case succinctly, for fear of occupying too much space, and will bring my communication to an end without further comment. I am, Sir, yours faithfully,

Louisville, Kentucky, U.S., Jan. 7th, 1885. JAMES WEIR, M.D.

Mr. C. C. Whitefoord may, we think, rest content with the strong expression of opinion on the part of the judge and the jury. It is scarcely necessary to publish our correspondent's letter.

"DEGENERATION OF LONDONERS."

To the Editor of THE LANCET.

SIR,—I venture to suggest that degeneration occurs amongst Londoners principally from early sexual indulgence and syphilis, apart altogether from deficiency of food or air. A very little experience in practice, especially among the poorer classes, will convince anyone that the extent to which Londoners suffer from syphilis is appalling.

I am, Sir, yours truly,

Feb. 9th, 1885. OBSERVER.

THE NEW TEACHING UNIVERSITY.

M.R.C.S. and L.S.A. recommends that the course of study be the same as in the Scotch Universities. But his further recommendations are peculiar—that those who are ambitious only for the College and the Hall qualifications should be given the M.B. and C.M. degrees, while those who would aim at passing the examination of the Royal College of Physicians should be dubbed "M.D." This is rather arbitrary.

Mr. F. R. Fisher.—Next week.

"AN EASY METHOD OF APPLYING THE FORCEPS."

To the Editor of THE LANCET.

SIR,—I have for the last dozen years, or more, been in the habit of applying the upper blade of the forceps in the manner described in THE LANCET of to-day by your correspondent, Mr. Lucas; and as I can fully corroborate all the advantages he claims for it, I venture to encourage its general adoption in preference to the old method described in most of the works on midwifery. The tugging and persuasion that are often required to get the patient into the desired position are alike distressing and terrifying to both the sufferer and her friends, whilst if the method suggested be used the forceps may often be slipped on without the patient actually knowing when. I have generally found it sufficient to have the knees well drawn up without separating the legs, and it is really astonishing how easily the blade usually sweeps round the head into the required position.—I am, Sir, yours faithfully,

HENRY CARTMEL, M.R.C.S.

Carlton House, Manchester, Feb. 14th, 1885.

To the Editor of THE LANCET.

SIR,—In reference to Mr. Lucas's letter in the current number of THE LANCET on "an easy method of applying the forceps," I may say I have adopted precisely the same procedure for the past twenty years. I learnt it from my father-in-law, who practised it thirty years before, and he got it from someone else. So it would not appear to be *very* new.

I am, Sir, yours obediently,

Lewes, Feb. 16th, 1885. J. G. BRADEN, M.R.C.S., L.S.A.

*** We have received many other letters showing that the suggested method of applying the forceps is by no means new.—ED. L.

MR. LEAKE AND THE ANTI-VACCINATIONISTS.

THE demands on our space this week will not permit our treating the above-named subject at the length its importance merits. We must therefore defer our comments until our next issue.

A QUERY.

To the Editor of THE LANCET.

SIR,—I shall be greatly obliged if any of your readers would kindly inform me of any school to which a child nine years old could be sent. She is one of four or five children, none of whom can speak intelligibly—saying only a few simple words, and those only half articulated. She has had no illness, but is very perverse, and develops frequently a strong tendency to mischief and destruction, tearing clothing, breaking windows and furniture, &c. Such fits last about a day; in the intervals she is very intractable and disobedient. I regard them as evidences of epileptiform seizures, with tendency to insanity. The parents are related (cousins, I believe); no other family history. They are able to pay.

I am, Sir, yours truly,

Seaforth, Feb. 18th, 1885. F. F. G.

COMMUNICATIONS, LETTERS, &c., have been received from—Mr. Voight; Messrs. Moxley and Harrison, Barbadoes; Dr. Bate; Dr. J. Gairdner, Crieff; Mr. C. Leslie, Manchester; Mr. G. S. Robinson, London; Mr. A. G. Williams, Brixton; Dr. Fairbank, Doncaster; Mr. H. E. Armstrong, Newcastle-on-Tyne; Mr. L. Newton; Messrs. Burgoyne, Burbidges, and Co.; Mr. Partridge, Stroud; Messrs. Essinger and Neuberger, London; Mr. J. J. Foley, Midleton; Mr. Cartmel, Manchester; Mr. Porter Smith; Mr. H. Allingham, London; Mr. Leake, Manchester; Mr. Crouch, London; Dr. Easby, Peterborough; Mr. G. Rice; Dr. Dudfield; Mr. C. P. Moir, London; Mr. T. P. Stephens, Emsworth; Mr. A. Drysdale, Mentone; Mr. G. A. Wright, Manchester; Mr. J. N. Marshall, Glasgow; Mr. J. R. Clinical Lecture
ON
MALFORMATIONS OF THE HEART.

Delivered at the Hospital for Sick Children, Great Ormond-street,

BY ROBERT J. LEE, M.D., F.R.C.P.

GENTLEMEN,—Cases of congenital heart disease in infants and children are generally of great interest—perhaps because they are not very common, or because exact diagnosis is difficult. At one time this difficulty of diagnosis aroused an interest in my own mind; but time, observation, and reflection have altered my views, and presently I will explain to you as briefly as possible the reasons why. We will begin, as usual, with a case, a typical one, of congenital malformation of the heart, and of rather common occurrence. The boy is now in fairly good health. According to the mother's account he has never been so well. He is between five and six years of age, is well grown and well nourished, and there is no complaint made of disturbed health except a slight cough. We have had him under observation for several months, and his mother says that he was brought to this hospital between three and four years ago, when he was about eighteen months old. We are told that he had three convulsive attacks at that time, but there does not seem to have been any reason for suspecting disease of the heart—at least, no intimation of this was given to the mother. When he came the second time, some months ago, there was then nothing very definite in the symptoms. He suffered chiefly from a disinclination for exercise or movement, from occasional swelling of the joints of the knees, feet, and hands; and he had spots of rather bluish ecthyma on different parts of the body. It was the fact of these symptoms being indefinite, and perhaps more particularly a peculiar expression of anxiety in the face, that made us at once suspect some cardiac trouble.

If you examine the boy's heart, you will find very much the same signs to-day as when he was examined a few months ago. You can hear a loud prolonged murmur over the præcordial region, but loudest a little below and to the left of the nipple; and you can follow the murmur round the axilla to the angle of the left scapula, where it is much fainter than in front, but still very distinct; it is systolic, but more prolonged than the ordinary mitral murmur of rheumatic origin. The liver was enlarged, for its margin could be felt midway between the umbilicus and the right costal boundary line. The treatment was active and satisfactory. We relieved the circulation by leeches applied over the heart, encouraging the hæmorrhage by fomentations. We ordered full doses of digitalis combined with the mixture of iron and magnesia; and, lastly, we enjoined perfect repose. As you see, the impulse of the heart is considerable, but the contractions are regular, and not very rapid, not more than 80 in the minute, and less probably if the boy were not a little excited. The clubbed condition of the fingers which was noted some months ago has disappeared, the skin is quite healthy, and there is no swelling of the joints; in fact, there is nothing particular to observe in the case except the cardiac murmur and some coarse crepitation in the lungs, due probably to a recent mild attack of bronchitis, or to slight congestion from the condition of the heart.

The case is not complete without an inquiry into the possible origin of the malformation. The first symptom of serious disturbance of the child's health was when he was ten months old, and then his breathing was at times oppressed, and there were other symptoms, although not at the time understood, yet clearly sufficient to decide the question of the congenital character of the cardiac defect. Two possible causes are given by the mother. One is that three weeks previous to the birth of the child she had a serious fright from a fire breaking out immediately behind the house in which she was living. Her anxiety was increased from the fact that her husband kept an oil-shop, and there was imminent danger of a conflagration on their own premises. The child was born rather prematurely, in consequence it was thought of this accident. The other cause is somewhat different. The father was the subject of severe rheumatism, and though we cannot ascertain distinctly the cause of his death, yet we are told that it happened rather suddenly eight months after the birth of this child. The relation between the father and the boy's condition is simply this—that if the former were the subject of disease of the heart of rheumatic nature at the time of conception, we know by experience that this may be the cause of cardiac malformation in the offspring. Which of these two causes was the potent one in this case I am not prepared to say. It is true that the most common cause of this kind of malformation is maternal trouble; but in giving you the complete history and all the facts, I have indicated a possibility worthy of attention and recollection. There is one point to be noticed before we discuss the nature of the cardiac defect, and that is the convulsive attacks which occurred at the age of eighteen months. They were not ordinary convulsions such as we are familiar with in infancy. They were rather long attacks of passive coma, without muscular spasm, and were alone sufficient to suggest some cardiac trouble. I have already pointed out, when considering the subject of convulsions in infancy, that this form of so-called convulsions presents a striking contrast with the form we are most familiar with. I think that the importance of carefully examining the heart in infants when the convulsive attacks are of comatose character was then mentioned to you.

Now we will consider what is the probable condition of the heart. Though we may not be able to diagnose for certain the exact nature of the malformation, we can arrive at conclusions exact enough for all practical purposes. In this case I think we may conclude that the defect is situated in the ventricular chambers, and that in all probability it consists of a communication between them somewhere in the interventricular septum. This is not an uncommon form of malformation. As you might imagine, the most common form is a communication between the auricles from non-closure of the foramen ovale. The auricles thus become practically one chamber, and we judge of the extent to which they are partially divided by the general condition of cyanosis. But if you expect to find a murmur present in most cardiac malformations you will perceive on reflection that this is unreasonable. In the majority of cases the chief physical sign is rapid and increased action of the heart, and not what we have observed in the case before us. It is for this reason that we must attend more to the general evidences of disturbance of the circulation than to the stethoscopic examination, and even when there is a distinct cardiac murmur we must look rather to the former than the latter in giving a prognosis. If we take a general view of this question, we shall see that it resolves itself into an hydrostatic problem, where the point we have to determine in any particular case is not so much the locality where the two blood currents, the arterial and pulmonary, are confluent, but rather the extent to which confluence is permitted by defects in the chambers or vessels which contain the fluids.

Imagine that we have two tubes of equal size placed parallel to one another, and that water or any other fluid is flowing through them in a similar direction, and at the same pressure. If we open a communication between these tubes by a cross tube interposed at right angles, no effect is practically produced upon either current; but if the cross tube is inclined at an angle between them, there is a tendency for a current to be established along the interposing tube. You can easily perceive that the size and the direction of a communication between two currents determine to some extent how far one mingles with the other. In a closed circuit the conditions are somewhat different, and we have to consider the difference of pressure on either side of a communication between the two systems.

In the case before us, for example, there is probably a a current from the left ventricle into the right during each contraction, with little if any current in the opposite direction, at least if there is it must be during the diastole. I think that if the right side of the heart were much congested, and the fluid pressure were increased, there would be more trouble, and cyanotic symptoms would exist as at the time when the leeches were applied. We will not consider this subject any further now, as you can pursue it at your leisure without my assistance. It only remains for me to say a few words on a line of research which I have no doubt has occurred to you as likely to aid in diagnosis—namely, the examination of the numerous specimens exhibited in most museums, or the descriptions to be obtained from various sources of different kinds of malformation. It is

rather curious to find that a good many of the specimens in museums were accidentally discovered, and prove chiefly that persons may live without suspicion of anything being wrong with the heart for many years. In other respects these specimens from having no history attached to them are not of much value.

A classification may be made from such a collection of specimens, and certain general conclusions may be drawn, but when this is done you are not much assisted in the diagnosis of any particular case. There is one thing certain, after all, and that is that general symptoms must be relied upon rather than physical signs in deciding the probabilities of life being supported under the circumstances. A large number of cases soon terminate fatally, and by soon I mean within a few weeks or months from birth. It often happens that, provided the greatest care is taken of an infant, it exists until an accidental exposure to cold induces some complication such as bronchitis or pneumonia, or it becomes the subject of convulsive attacks, which soon prove fatal. In many cases the distress of the infant is very painful to see, and we need not hesitate when expressing faint hopes of life to point out how little its prolongation is to be desired where the suffering is so great. Among those who have made the subject of malformations one of special study, and to whom we are much indebted for carefully described examples, as well as important generalisations, I must not omit to mention the name of the late Dr. Peacock. It is associated in my mind with such estimable qualities of intellectual and moral character that I mention it with deep respect and affection, and when I recommend to your attention the writings of this distinguished physician and pathologist, I do so in the conviction that you will derive great satisfaction and profit from the perusal of his works. In the Transactions of the Pathological Society some of his most important contributions will be found. In vol. xxxii., p. 35, there is a brief but valuable summary of what he described as "the most common kind of deviation from the natural conformation of the heart," the cases where the aorta communicates with both ventricles through deficiency of their system.

Seeing that we must be guided so much more by the general symptoms, in our diagnosis and prognosis than by the physical signs in this class of cases, you will appreciate my reasons I hope for attaching more importance to the former than the latter; and though it it not my wish to discourage you from carefully determining physical signs, it is proper that you should not attach too much importance to them, or hope for as much assistance in diagnosis as we are accustomed to derive when dealing with other forms of cardiac disease.

ON VISCERAL SYPHILIS.

BY J. S. BRISTOWE, M.D., F.R.S.

(*Concluded from p. 333.*)

THE next case is one in which, together with a number of lesions that were regarded at any rate for a time as due to disseminated cancer or sarcoma, there was a condition of knee-joint exactly such as was found in the case forming the text for my paper. In this case also recovery under specific treatment seems to have been complete and permanent.

CASE 3. *Tertiary Syphilis affecting Testicle, Glands of Neck, Clavicle, Knee, Sacro-iliac Synchondrosis, &c., and simulating Malignant Disease of these Parts; Cure.* In the early part of the year 1872 I saw in consultation a gentleman about twenty-eight years of age. He had been a very healthy and athletic man, and, in fact, took a leading position among the promoters of athletic sports in the metropolis. He had been married for some months, and at the time of marriage was, he said, perfectly well. About six months ago, shortly after his marriage, one of his testicles began to enlarge, and then at irregular intervals other swellings became developed in connexion with one of the collar-bones, the glands beneath the angles of the jaw, one of the sacro-iliac synchondroses and the left knee. The last of these appeared a few weeks before I saw him. At the time of my visit he had lost much flesh, was exceedingly anæmic, very weak, and wholly confined to bed. He had been suffering from much pain and want of sleep, and was very low-spirited. On examination I found the glands under the angles of the jaw enlarged and hard, and those on one side forming a lobulated mass about the size of a duck's egg. The central part of one of the clavicles was swollen, painful, and tender, the swelling being about as large as a small Tangerine orange. One of the testicles was large and tender, apparently about the size of a cricket-ball; but there was effusion of fluid into the corresponding tunica vaginalis, which prevented an exact determination of the size of the testicle; but collectively the tumour was as big as a large cocoa-nut. One knee was very much swollen, painful, and tender. Its cavity contained a good deal of fluid; but also the solid tissues were thickened, and especially this was the case over the lower end of the femur, suggesting that the affection might have begun from this part. There were also swelling, pain, and tenderness over one of the sacro-iliac synchondroses. Further examination showed that there were a few large indurated glands in the groins, but that there was no evidence of glandular tumours elsewhere, or of visceral disease of any kind. What was the patient suffering from? I confess that my primary thought was (and this was, I believe, the view of his medical attendant), that he was the subject of some kind of malignant disease, either lymphadenoma or a variety of sarcoma. This view, I thought, best explained the gradual and unaccountable onset of his disease and the general diffusion of morbid growths, and seemed to be confirmed by the fact that he had never to his knowledge had primary syphilis or experienced any secondary symptoms. Still I was not quite satisfied with this opinion, and, moreover, was anxious to be able to take a hopeful view. And on pushing my inquiries I found, in the first place, that though, as far as he knew, he had never had syphilis, and certainly had no scar of old chancre, he had before marriage lived loosely, and might well have contracted the disease; in the second place, that the glands in the groin had become enlarged about three years previously, their enlargement being referred at the time to over-exertion in connexion with athletics; and lastly, that about fifteen months ago a swelling had appeared in his calf, which had ulcerated and formed a deep unhealthy sore, that the sore had spread until it had become nearly as large as the palm of the hand, and that at the end of six months it had healed, leaving a large irregular depressed cicatrix, which still remained. I concluded that this was really a tertiary syphilitic ulcer, and that there were good grounds after all for at any rate hoping that his complex disorders were also syphilitic. A few days later Mr. Timothy Holmes saw the case with us, and came to the same opinion that we had done. The patient was consequently put under a course of mercury and iodide of potassium. I heard no more of my patient until two or three years later, when I was asked to see him again in consultation. He was suffering from an attack of rheumatic fever. I then learnt, that he had rapidly improved under antisyphilitic treatment; that in the course of a few weeks he had been able to be removed to the seaside; and that at the end of a few months he had been restored to health. On the occasion of this visit, I found practically no traces of the various inflammations and tumours which he had formerly presented. I know that he was alive and carrying on his business, and presumably therefore well, a year ago.

I may be allowed to explain that I have not ventured to say on which side of the body the specific lesions were; because while I have a vivid recollection of all the more important features of the case, I am mainly indebted for the above description to the notes of an old clinical lecture of mine which states the facts briefly, but omits to specify these particulars, doubtless because when I gave the lecture there was no need to remind me of them.

The next case is one mainly of abdominal syphilis—that is, of syphilitic affection with gummata of the liver and spleen, and consequent ascites. It illustrates the abdominal phenomena (excepting obstruction of the vena cava) presented by my first case. In both the tumours were at first so large and irregular as to suggest the presence of malignant disease; but in the last, though they have not disappeared, they have become quiescent, apparently under the influence of iodide of potassium and mercury; and even in the case now under treatment there is distinct evidence that the growth has become arrested, even if it be not shrinking. In the case I am about to quote it will be observed that latterly the patient has been also suffering from intracranial syphilitic disease.

CASE 4. *Tertiary Syphilis; Enlarged Liver and Spleen; Ascites; later, Paralysis of Portio Dura; Incomplete Recovery.*—Ellen M——, a telegraph clerk and also a prostitute, aged thirty, came under my care on March 17th, 1882. Her history was not accurately known while she was in the hospital on this occasion. But it was ascertained some months later that she had been earning her livelihood mainly by prostitution for some time, that she had indulged largely in alcohol, and that she dated her present illness from an injury received a year and a half previously during a violent struggle with a man who, after having had connexion with her, tried to rob her of her jewellery. From that time she had suffered from increasing weakness and emaciation, pain in the epigastrium, and nearly constant vomiting after food. Eight months ago a tumour was detected in the epigastrium, which has since got larger. Latterly the catamenia have been absent. She has never had any skin eruption. She was thin, somewhat pale, and complained of shortness of breath, and cough attended with expectoration of viscid mucus, and also of enlargement of the belly, with sickness, epigastric pain, and tenderness. The heart was healthy, but there was some degree of dulness and a good deal of smallish crepitation over the lower part of both sides of the chest. The abdomen was large, but did not distinctly contain fluid. There was a hard, prominent, rounded, irregularly nodulated tumour, filling up the epigastrium, and measuring six inches transversely by three inches vertically. This was evidently the prominent portion of a much enlarged liver, for the lower edge of this organ could be traced from the right anterior superior spine of the ilium obliquely upwards to the junction of the eighth and ninth left costal cartilages, passing in its course about two fingers' breadth above the umbilicus. Just to the left of the liver the enlarged spleen could be felt emerging from beneath the ribs, its lower end reaching to midway between the ribs and the crest of the ilium. The liver dulness commenced at the upper border of the fifth rib; the splenic dulness commenced at the upper border of the eighth rib in the mid-axillary line, and extended downwards for seven inches. Tongue fairly clean; bowels regular; urine, sp. gr. 1019, high coloured, but free from bile, and without albumen; temperature normal. There was little change in her condition while in the hospital. On the whole, however, she improved a little. Her cough, which was attended with occasional slight hæmoptysis, nearly disappeared; her vomiting diminished; and her appetite returned to some extent. Her catamenia also returned; but there was no appreciable change in the size of the liver and spleen. The blood was examined, and found not to contain any relative excess of white corpuscles. She left of her own accord on April 15th. Five months later I saw her at her own lodgings. She was then decidedly worse, and seemed very ill. She was sallow, but not actually jaundiced. The abdomen contained a large quantity of fluid; the liver and spleen were much in the same condition as before; and the veins in the upper part of the abdominal walls and in the lower part of the thoracic walls were dilated. It was now that I heard the true history of the case; and I was confirmed in the view I had previously formed, that the enlargement of the liver and spleen was largely due to the growth of gummata.

Some months after this she was in King's College Hospital, under the care of Dr. Buchanan Baxter, still suffering from ascites, for which she was tapped. She was very ill then, and it was expected she would die; but she improved, and left the hospital fairly well. During the greater part of the time to which the above notes relate she was under anti-syphilitic treatment. On July 9th, 1884, she was readmitted into one of my beds. Ten days previously she dreamt that she had a fit, and on getting up in the morning found her face drawn to the right side, that she could not close her left eye, and that she was deaf of her left ear. On admission, she was suffering from frontal and vertical headache, sickness, drowsiness, loss of memory, and low spirits, complete paralysis of the left portio dura, deafness of the left ear, and slight weakness of both external recti, with double vision. She had no other paralysis, and the soft palate was unaffected. On examining the abdomen, no ascites was found, but the liver was still large and hard, and its edge reached to the umbilicus, and the spleen was also large and hard, and extended three inches below the ribs. She remained a month under treatment, and improved; but when she left she was still forgetful, still deaf, and still had complete paralysis of the portio dura.

The case with which I shall conclude, though interesting in itself and in its bearing on that of the gentleman athlete already detailed, has no direct relation to the case on which my paper is founded. It was an obscure case of disease of the testis and cervical glands, associated with albuminuria and dropsy, in which there was room for difference of opinion as to the nature of the affection, but in which the prevailing belief that it was syphilitic seemed confirmed by the results of treatment.

CASE 5. *Tertiary Syphilis; Enlargement of Glands in Neck and of Testicle; Albuminuria; Relieved.*—Charles H——, a butcher aged thirty-six, was admitted under my care on the 25th October, 1882. The history is somewhat obscure. He did not acknowledge having had syphilis; but said, that he had been liable to cough with expectoration for years; that six years previously he had struck one of his testicles, which became swollen and then diminished in size, and that a year ago he damaged the organ again, since when it has gradually enlarged; and that about three months ago he first noticed swelling of his legs, and at the same time suffered from lumbar pain and sickness. He is a well-nourished man, with some œdema of face and legs, penis, and scrotum. He has a hard and somewhat tender lump about the size of a large walnut behind the left sterno-mastoid, and another similar one under the angle of the right jaw. The left testicle is about the size of a child's fist; it is very hard, somewhat irregular in shape, adherent to the skin, and tender. Its exact shape and bulk are somewhat masked by the œdema of the scrotum, and it is impossible to distinguish testicle and epididymis. The breath sounds are harsh at the right apex, and the urine, which has a specific gravity of 1012, contains a large quantity of albumen. With these exceptions there is no evidence of visceral disease; the tongue is of a general beefy-red colour, void of papillæ, deeply fissured (mainly in the transverse direction), and studded here and there with patches of fur. He has no vomiting now; his appetite is fair, and his bowels are regular. There was a good deal of speculation as to what was the nature of this patient's malady. Was he suffering from tubercle? Was he suffering from some malignant growth, or was his disease syphilitic? It is evident that much might have been adduced, and much was adduced, in favour of either of these views; and it may be worthy of remark that the patient was sent to the College of Surgeons for the purposes of one of their practical examinations, and that there was considerable divergence of opinion among the examiners. On the whole, however, the balance of opinion was in favour of the syphilitic nature of the glandular tumours in the neck, and of the enlargement of the testis; this view being based partly on the hardness of the tumours, partly on the slow growth of the testis, and partly on the peculiar condition of the tongue, which some persons, and especially my friend and colleague Mr. Clutton, regarded as a characteristic outcome of combined smoking and syphilis. For two or three weeks after the patient's admission there was no improvement. Indeed, the glands in the neck slowly got larger and a third tumour of the same kind was added to them, and the testis also underwent some slight increase of bulk. At this time he was not treated with iodide of potassium and mercury; then these drugs were administered, and during their employment there was manifest amelioration of the tumours, both in size and as regards tenderness. In other respects he continued without change. His œdema persisted; he was thirsty, passed a good deal of urine (generally between sixty and a hundred ounces in the twenty-four hours), and had to relieve his bladder frequently. The specific gravity of the urine was generally about 1012, but occasionally (when the quantity passed diminished) rose to 1020. It contained a large quantity of albumen, generally one-half, but never presented distinct casts. What the nature of the kidney disease was I do not know, but I think it not improbable that the organs were the seat of lardaceous degeneration. The patient left the hospital on the 29th of November.

I have little to add by way of comment. It will be admitted, I think, that the cases I have quoted illustrate point by point all the interesting features of the case still under my care; and that collectively they justify (if such justification be necessary) the diagnosis which has been arrived at. At any rate it will be admitted, I think, that the whole group of cases is very interesting and instructive.

There is one matter of great practical importance which most of the cases bring into prominence—that is, that tertiary syphilis may be present in the most aggravated form in adults who are perfectly ignorant of having ever

had either primary or secondary symptoms of the disease, and who present no discernible traces of any such antecedent affections. This is less surprising, perhaps, in the case of women than in that of men, because while secondary symptoms in either case are often very trivial and apt to be overlooked, a chancre in women may easily occupy a position which neither involves present discomfort nor leaves a scar where it can be distinctly seen. In the third case of my series, that of the gentleman athlete, there was not only no history of primary or secondary syphilis, and no knowledge of the fact that the disease had ever been contracted, but a skilled surgeon failed to discover any local evidence of a former chancre. There is no reason whatever to suppose that the disease in any of the cases was congenital.

One other point I may refer to—namely, the causation of the venous obstruction. I am not aware that the walls of veins suffer from syphilitic thickening, with consequent thrombosis, as do the walls of arteries; nor, so far as I know, do veins become obstructed by clots in the course of constitutional syphilis, excepting as in tuberculosis and cancer, when the patient is in the last stage of cachexia. I am hence disposed to believe that in the two cases of obstruction of the vena cava the obstruction was due to the compression of the veins by adjoining gummatous growths; and, further, that it is due to this circumstance that in the one case the cava soon became pervious again; and that in the other, even after the obstruction has existed for two years, there are already indications that it is in process of removal.

ON A CASE OF PROGRESSIVE ANÆMIA.[1]

CURED BY IRON AFTER FAILURE OF ARSENIC TO AFFORD RELIEF.

BY DAVID W. FINLAY, B.A., M.D., M.R.C.P.,
PHYSICIAN TO THE MIDDLESEX HOSPITAL AND TO THE ROYAL HOSPITAL FOR DISEASES OF THE CHEST.

THOMAS B——, aged forty-five, a wheelwright by occupation, came under my care at the Middlesex Hospital on Nov. 25th, 1881, with the following family and personal history. His parents were both dead, the father at the age of sixty-three, from some form of heart disease, the mother from an unknown cause. Of a family of five brothers and five sisters three of the former and two of the latter survive. One sister died of consumption at the age of sixteen, the others in childhood from unknown causes; two brothers and one sister surviving suffer from rheumatism, one of the brothers having had two attacks of rheumatic fever. As a lad the patient had suffered much from headaches. He had had an attack of ague at the age of fifteen, followed by two others about the age of eighteen. Five and a half years before admission he was laid up with what he was told was "congestion of the liver and inflammation of the kidneys." He was ill then for twelve weeks, but was able after that to return to his work. Two years ago he lost his appetite and began to complain of increasing weakness. For eighteen months he has been troubled with pain in the loins and interscapular region, frontal headache, watering of the eyes, dimness of sight and noises in the head. About ten months since he suffered a little from "piles," and occasionally lost blood. For the last six or seven months he has observed himself becoming pale, and the paleness has gradually increased. He has also been troubled with shortness of breath on exertion. Two months ago for a short time he had frequent diarrhœa accompanied by abdominal pain, coming on immediately after food. A month since he brought up blood without coughing to the extent of half a teacupful. His feet and legs have lately swelled towards evening. He has been a temperate man all his life.

On admission his pulse was 96, of fair volume, but compressible; temperature 99°; respiration 24; the tongue clean, very pale, and rather dry. He was a fairly-nourished man, older looking than his stated age. He complained of great and increasing weakness, and shooting pains about the back and loins. He was markedly anæmic-looking, the visible mucous membranes being very pale, and the skin having a waxy appearance and faint yellow tinge. The skin of the axillæ and of the inner and anterior aspect of the legs and ankles was dark and mottled, but there were no spots of pigmentation about the lips or mucous membrane of the mouth, and the areolæ round the nipples were not dark. The muscles were soft and flabby, but not wasted. There was slight pitting on pressure over the ankles and shins. As regards physical examination, the lung resonance was everywhere good. Below the right clavicle the expiration was a little prolonged. There were no adventitious sounds, except at the extreme bases, where scanty crackles were heard at first on deep inspiration. The heart's sounds were well pronounced at the apex, which appeared to be in the sixth interspace, an inch outside the nipple-line, where the first sound was accompanied by a well-marked blowing murmur. At the base the sounds were scarcely audible. A loud venous hum was heard over the jugulars on both sides of the neck. There was no enlargement of the liver or spleen, or of the glands in the neck, axillæ, or groins. The urine had a specific gravity of 1024, and was acid and free from albumen. The blood, estimated by the hæmacytometer, was found to have a corpuscular richness of 23 per cent. (1,150,000 red corpuscles in the cubic millimetre). Under the microscope the blood showed the corpuscles aggregated in masses rather than in rouleaux. The white corpuscles were not in excess. No retinal hæmorrhages were observed with the ophthalmoscope. The patient was at once put upon arsenic (five minims of the liquor arsenicalis three times daily) with three ounces of port wine, and a diet consisting of fish, beef-tea, milk, and an egg, the arsenic being increased to eight minims for each dose on Dec. 1st, a week after taking the smaller quantity. A note made on Dec. 4th states that he was sick during the previous night, but had no pain or diarrhœa. His tongue was clean and pale, and the colour of the face had not perceptibly improved. The blood, estimated again by the hæmacytometer on Dec. 7th, showed no change. I accordingly determined to give the arsenic in another form, and ordered for him an eighth of a grain of arseniate of iron in pill, to be taken every six hours, and he went on with this for six days. Two days after commencing to take the arseniate he complained of slight diarrhœa, which, however, increased, and was accompanied by griping pain in the abdomen. This I attributed to the arsenic, and ordered it to be discontinued, and the diarrhœa ceased the following day.

Examining the blood on Dec. 15th, I found the corpuscles numbering only 21·2 per cent. of the normal, and it seemed that he was not a whit the better, but rather worse, for the arsenic he had taken. On this day, therefore, I ordered him three grains of dried sulphate of iron in pill three times a day, and on the 19th (four days later) it was noted that his appearance was less anæmic and that his condition was generally improved. On Dec. 26th the blood showed a richness of 47·8 per cent. (2,390,000 per cubic millimetre), being an increase of 24·8 per cent. (or 1,240,000 per cubic millimetre) since the treatment with iron was begun—namely, in ten days. A few days later it was noted that the apex murmur was less marked than it had been. On Jan. 4th, 1882, the corpuscles were 45·8 per cent., and he felt stronger and was able about this time to go into the garden on fine days. On Jan. 9th, when he had been taking the iron for nearly four weeks, I thought that a little arsenic might prove helpful along with it, and he was ordered five minims of the liquor arsenicalis with infusion of calumba, three times a day, the iron still being continued. On Jan. 16th the corpuscular richness of the blood had reached 72·8 per cent. (3,640,000 per cubic millimetre); the heart's apex was within the nipple-line, the murmur inaudible; the muscles were much firmer; there was no œdema of the ankles present; the pulse was regular and of good strength; the man's whole appearance was considerably improved, and he felt much better. On the following day he was sent to the seaside. He returned on Feb. 11th, having a very good colour, and stating that he felt quite well and was able to return to his work, having no shortness of breath on exertion. About a month after his return I had an opportunity of examining his blood again, the result being 91·2 per cent. of corpuscular richness (4,590,000 per cubic millimetre). Six months later he was reported to me as having continued quite well, and being regularly engaged in his work. I saw him last week, and he still continues well, although not robust. I ought to add that I was unable to estimate the hæmoglobin percentage, and that only one ophthalmoscopic examination was made.

[1] A paper read before the Medical Society of London on February 16th, 1885.

I have brought forward the foregoing case chiefly on account of the considerations it presents from its therapeutical side, but in view of recent writings on the subject the two sides of diagnosis and treatment are so bound up that it seems impossible to discuss them separately. I have called it a case of progressive anæmia, because although not progressive in the sense in which the word is used when coupled with "pernicious"—i.e., progressive to a fatal result,—it has seemed necessary to give it a name which would serve to indicate the opinion that it belongs to the same class; and in this sense a certain amount of progress might be predicated of it, just as of other diseases which go in a downward direction until a turning point is reached. If Addison's name of "idiopathic anæmia" be preferred, it need not be objected to, except for this, that when we have labeled a disease "idiopathic" there is a danger that we may be drawn away from the endeavour to seek for causes the discovery of which would render the name no longer appropriate. But the name is of the less importance if we are agreed about the thing, the essence of which, as laid down by Dr. Pye Smith in his able and exhaustive paper in the twenty-sixth volume of Guy's Hospital Reports, is "its being primary, not the result of hæmorrhage or of organic disease, and simple, not part of a more general condition." Judged by this test I would submit that the case belongs to the so-called idiopathic class. It has no doubt been observed that my patient had suffered from ague in his youth, and it may be suggested that this may have had some influence in determining his attack of anæmia. But it should be remembered that he had no splenic enlargement and no excess of white corpuscles; and the ague was separated by an interval of twenty-seven years from the illness for which he came under my care, an interval during which his health had been generally good.

Again, the loss of blood which he suffered from hæmorrhoids was not sufficient in amount to account for his anæmia; and besides, as it occurred long after increasing weakness was complained of, I should look upon it not as a cause, but as a consequence of the anæmic state. The same remark would apply to the blood which he brought up a month before coming under my observation. In regard to these points I may quote Dr. Pye Smith, who says, "The vague statements of a man of forty-seven, that when young he suffered once or twice from fever, cannot seriously affect the case." And again, "The remarkable fact is that we find progressive and fatal anæmia to come on with no assignable cause; and this being admitted, one may well doubt whether preceding dyspepsia, or slight hæmorrhage, or pregnancy should be regarded as more than a coincidence."

I wish especially to call attention to the fact that, contrary to recent experience, treatment with arsenic alone appeared to do no good, and that improvement began from the time that iron, in the form of dried sulphate, was prescribed. I am aware that in the eyes of some this fact is sufficient to remove the case from the Addisonian category. According to others, the man's recovery would seem sufficient to support the same argument. But both of these positions are surely based on unscientific grounds; for it seems equally unreasonable to diagnose a case on the one hand by treatment, and on the other by result. I am not aware that we adopt the same method in the case of other diseases. If arsenic were an absolute specific, something could be said in favour of the former method, and for the other if such cases were uniformly fatal. But neither of these positions is correct, for arsenic has frequently failed to effect a cure, and cases of the kind occasionally recover. Dr. Pye Smith tabulates twenty such cases, in seven of which treatment by arsenic was successful, in five iron, in one iron and arsenic, and in two transfusion. The remainder were not medicinally treated at all.

I would venture to suggest for discussion whether all distinctive names are not undesirable—whether, in fact, anæmia, apart from hæmorrhage and organic disease, is not a unity, comprising, like other diseases, cases which recover under appropriate treatment and cases which, in spite of treatment, run on to a fatal result. There seems, indeed, to be no single distinctive sign in the class of cases under review, except death, by which they are commonly diagnosed. Even the retinal hæmorrhages, which at first were regarded as pathognomonic, have been shown by Dr. Stephen Mackenzie to be liable to occur in anæmia, however brought about, when the corpuscular richness of the blood falls below 50 per cent. of the normal.

In a good many of the cases reported chlorosis is given as an antecedent condition, and this seems to supply an argument in favour of the unity for which I plead. The same consideration must be drawn from what Immermann has written on the subject under the name of "pernicious anæmia." He speaks of it occurring in cases "as a complication supervening on an ordinary idiopathic or symptomatic anæmia, the true causes of the complication being totally unknown." "Moreover," he says, "I am inclined to put the same interpretation on those cases of chlorosis in which, after the usual symptoms have lasted a variable time, and the diagnosis has been correctly established, ... the patient succumbs at the end of a few weeks in a state of utter prostration and in spite of the most vigorous tonic treatment. We can hardly avoid the conclusion that the disease was at first a simple chlorosis, and that at a given moment certain fresh causes of an unknown order came into operation and modified the usual symptoms of chlorosis, so as to make the disease assume the character of a pernicious anæmia"; and Dr. Mitchell Bruce, in "Quain's Dictionary of Medicine," says that "the symptoms of simple chlorosis are those of mild anæmia, with certain important differences, which become fewer and less marked, and finally disappear, as chlorosis advances to the more serious disease."

I think we can only deduce from all this that anæmia, apart from hæmorrhage or organic cause, is one disease, beginning, as a rule, mildly, and being in the majority of cases curable (whether by iron or arsenic does not matter, for arsenic is often useful, even in the milder cases), but that in a certain proportion of cases it continues its downward course, becomes "pernicious," and ends in death. Such a conclusion is supported in the main by Dr. Coupland in the Gulstonian Lectures for 1881. He there states that "the symptoms of pernicious anæmia are those of simple anæmia aggravated and intensified," the effects being also "the same carried to an extreme degree."

It is instructive, in conclusion, to note that, according to Dr. Coupland, the great majority of the cases occur between the ages of forty and sixty in males, and between twenty and forty in females. May not a reason for this be found in the fact that as individuals advance in life they gradually come to have less power of repair, the younger average in females being accounted for by the additional strain thrown upon them in connexion with child-bearing and lactation? If so, such a consideration would still further tend to break down the distinction between simple and pernicious anæmia so-called.

ONE HUNDRED AND ELEVEN CASES OF LITHOLAPAXY.

BY P. J. FREYER, M.A., M.D., M.CH.
SURGEON, H.M.'S BENGAL ARMY; CIVIL SURGEON, BAREILLY, NORTH-WEST PROVINCES.

IN the December number of the *Indian Medical Gazette* of 1882, the February number of 1883, and the March number of 1884, three papers of mine appeared, in which full details of my first seventy-six cases of litholapaxy were given. Having now completed 111 cases of the operation, I propose dealing with them comprehensively in the present article, repeating some remarks recorded in the papers above alluded to, and adding some further observations of a practical nature which I have learnt from an increased experience of the operation. It is hoped that the record of a large number of cases of this operation from the practice of a single operator may prove interesting to the profession at large, and that the results obtained may have some effect in bringing into more general practice amongst my professional brethren in India an operation which, though still in its infancy, has undoubtedly a brilliant future in store for it.

The extreme aversion with which the natives of India regard any mode of treatment that involves several distinct surgical proceedings, extended over an unlimited period, is well known to every surgeon who has practised amongst the people of this country. The knowledge of this fact alone, putting aside altogether the comparative merits of lithotrity and lithotomy, was sufficient to deter surgeons from practising the old operation of lithotrity. When, however, some five years ago Professor Bigelow, of Harvard, U.S., introduced his new operation of "litholapaxy" to the

notice of the profession, and, scattering to the winds all previously held theories as to the deleterious effects of prolonged instrumentation in the bladder, demonstrated by a series of successful cases that, instead of subjecting the patient suffering from stone to a number of short sittings extended over an indefinite period, the calculus might be crushed and evacuated at one sitting, the chief objection to the crushing operation, so far as this country was concerned, seemed to have been removed. As with many of my professional brethren in India, lithotomy in my hands had proved a fairly successful operation. I did not therefore at first abandon the cutting for the crushing operation. I must confess, however, that the main cause of my hesitation in adopting the new operation was the depreciative manner in which it was criticised by Sir Henry Thompson on its first introduction. I need scarcely say that English surgeons have been in the habit of receiving as almost equivalent to divine law the utterances of that distinguished surgeon on any point connected with the surgery of the urinary organs. When, therefore, I read of the "disastrous" results that he anticipated from Bigelow's operation I naturally hesitated in adopting it. And it was not till I subsequently read of the brilliant results Sir Henry himself had obtained from that operation, with reference to which he had uttered such gloomy forebodings, that I finally decided on giving the operation a trial.

During the period that has elapsed since I adopted the operation of litholapaxy in my practice 203 cases of stone in the urinary passages have come under my immediate treatment. Amongst these there were four cases of impacted urethral calculus, in all of which external urethrotomy was successfully performed. There were seventy-five cases of vesical calculus in male children or lads under sixteen years of age. Lateral lithotomy was the operation performed by me in all these cases, and amongst them there was no death, all having made excellent recoveries. In the remaining 124 cases, all of which occurred in adult males, with the exception of three female children, the operation of litholapaxy was entertained, but for various reasons there were thirteen instances in which the operation could not be performed. Five of these latter were the subjects of severe stricture of the urethra, so that the instruments would not pass into the bladder; in one case there was a greatly enlarged prostate with tortuous urethral canal; and in seven cases the stone was so large that it could not be grasped by the lithotrite, or so hard that after being grasped the lithotrite could make no impression on it. In twelve of these cases I performed lateral lithotomy, with two deaths. In the remaining case the calculus was extremely large and hard, weighing over twelve ounces. In this case the suprapubic operation was performed, but the patient died six hours afterwards. I have considered it advisable to mention the above facts so that it may be clearly understood that the operation was given a fair trial, having been performed in every possible instance in the adult without reference to age, state of health, size of calculus, &c. It is in this way only that a true estimate of the comparative value of the operation can be obtained, and not by performing it in selected cases only.

A detailed description of the operation of litholapaxy would be foreign to the aim and scope of this paper. A word, however, about the instruments employed. The lithotrites used by me are: a large fenestrated instrument for crushing large and hard calculi; a smaller one of the same description for medium-sized and small stones; and a flat-bladed lithotrite for crushing débris. All these lithotrites are constructed on the well-known model of Thompson and Weiss, and admirable instruments they are. Recently I have had a very large and powerful fenestrated lithotrite constructed for me by Weiss on the same model. Its crushing power is excellent; but in dealing with very large and hard calculi, it might be rendered more efficient by some slight alterations that I shall have to suggest further on. The aspirator used by me is that modification of Bigelow's instrument known as Thompson's, and subsequently improved by Weiss. The evacuating cannulæ vary in size from No. 12 to No. 18. Larger than the latter I have not used, that being the largest size I possss. I have, however, met with a few cases in which a larger size might have been passed with ease, and I have, consequently, ordered a No. 20 cannula. The larger the evacuating cannula, the less necessity there will be for crushing the calculus into fine powder, and, consequently, the less time will the operation require for its performance—a matter of no small importance when we have to deal with a large stone in a patient whose constitution has been very much worn by the disease. It is, therefore, advisable to employ the largest cannula that will pass with ease into the bladder. I cannot too strongly deprecate the use of any force in passing a catheter, or, indeed, any instrument, into the bladder. The deleterious effects which Sir Henry Thompson anticipated from the use of large instruments experience has shown to be mythical. Sir Henry says that the instruments should be proportionate to the size of the stone; but experience has taught me that the capacity of the urethral canal is of much more importance in determining the size of the instruments, and that the largest lithotrite and cannula that can be passed without the use of any force should be employed. A large lithotrite is much handier in the bladder, less liable to get clogged by débris, much more efficient not only for crushing large calculi, but for disposing of fragments of débris, than a small one, and I fully agree with Bigelow that when one gets accustomed to the use of a large lithotrite he does not willingly abandon it for a smaller instrument.

The accompanying table will show at a glance some of the most important points connected with the 111 cases of litholapaxy, which are the subject of this paper. The subjects of these operations were all natives of India. All, with the exception of a few cases in private practice, were in-patients of the Civil Hospitals at Moradabad and Bareilly, throughout the whole course of their treatment. Detailed notes in every case have been kept by my assistant-surgeons and myself, and no case has been permitted to leave the hospital till he had quite recovered.

From this table it will be observed that amongst the 111 cases in which litholapaxy was performed there were four deaths. The details of these cases are as follows:—

CASE 7.—A Hindoo male, aged sixty-five, was admitted into the Moradabad Civil Hospital on September 21st, 1882, with symptoms of stone in the bladder, which had existed three years. There was painful and difficult micturition, with frequent desire to make water; passing of blood occasionally, and the urine for some months had been mixed with pus, giving a very offensive smell on standing. There was great enlargement of the prostate. A catheter was passed and about ten ounces of fetid urine drawn off. On passing a sound several small calculi were detected. The man's health was very bad. On September 2nd I performed litholapaxy. The operation lasted thirty-five minutes, the lithotrite being introduced four times. The débris weighed eleven drachms. No. 18 cannula passed easily—after previously slitting the floor of the meatus slightly—as far as the prostatic portion of the urethra, where some manipulation was necessary to pass it into the bladder. It was evident from the appearance of the débris that there were several calculi, varying in size from that of a pea upwards. Before withdrawing the cannula finally the bladder was washed out with a weak carbolic solution. In addition to the usual after-treatment, a catheter was ordered to be passed morning and evening, owing to the atony of the bladder and enlargement of the prostate that existed. During the first two days little urine passed except through the catheter. The urine continued fetid and sanious; the bladder was washed out daily, a faint trace of carbolic acid being added to the water. There was no pain, but the patient continued very anxious and depressed, and died on September 27th from exhaustion. No post-mortem examination was permitted.

(To be continued.)

REMOVAL OF A GUN-BREECH AND BOLT FROM THE NOSE AFTER FIVE YEARS.

BY RUSHTON PARKER, B.S., F.R.C.S.,
PROFESSOR OF SURGERY IN UNIVERSITY COLLEGE, LIVERPOOL.

THE patient, a farmer aged twenty-four, was brought to me by Dr. O. W. Griffith of Pwllheli, on Dec. 19th, 1883. Five years before a muzzle-loading fowling-piece had burst in his hands, laying open his face about the mouth and nose. The resulting wound had healed externally with a trifling scar and no deformity, under the the care of another medical man. About November, 1883, he consulted Dr. Griffith on account of a persistent fetid discharge of pus from his nostrils, and a sinus under the upper lip on the left side. The use of disinfectant lotions not having produced any improvement, it was concluded that a piece of necrosed bone was at the root of the evil. The examination by myself and Dr. Griffith showed entire absence of facial and buccal deformity, and the probe revealed nothing except a bare edge of bone when passed into the sinus under the lip. Exploration by either nostril, however, with dressing forceps was attended by contact with what was presumed to be a piece of dead bone, that could be seized and turned about, but not withdrawn, as the aperture was not large enough. So arrangements were made for operation under anæsthetic the next day, which was undertaken in lodgings the patient took for the purpose. The sinus beneath the lip was entered with a blunt-pointed bistoury, and the soft parts of the nose detached from the upper jaw by a horizontal incision along the mucous fold under the lip. Through the resulting hole the manipulations were made, in order not to mutilate the exterior of the face. The sequestrum forceps employed soon clicked with a metallic sound, and were withdrawn holding an iron screw bolt, at once suggesting that one had to do with parts of a gun, but the main object still remained, resisting at first all efforts at extraction, though freely movable round and round. The bony margins of the nostril were clipped with pliers to enlarge the opening somewhat, but even then the body did not advance. The sequestrum forceps missed their hold repeatedly, having become much distorted, and therefore almost useless. However, with the fingers, and with another pair of forceps used as a lever, the piece of metal was prised through the opening by forcibly pulling, wrenching, and wriggling. Examination with the finger failed to detect any further loose fragment, coming upon blood-clot and the sharp edges of the nasal septum and other bony corners presumably not necrosed. Much hæmorrhage naturally occurred, but was speedily arrested by washing with hot water. The patient was a full-blooded man of extremely strong build and middle height, and most bravely endured the operation, of which he must have felt the greater part, as the chloroform produced little or no effect upon him. Much soreness naturally followed all the next evening and night, in which he slept but little. The next morning early he took a breakfast of ham and eggs instead of the tea or beef-tea which had been recommended for him,

and he set off the same day for Pwllheli, where he has remained and progressed favourably ever since. In the first week of June, 1884, he was seen by Dr. Griffith, who found the incision under the lip healed without visible cicatrix, and the discharge from the nose a mere trace. The patient was free from all inconvenience.

Remarks.—This is the largest piece of gun-barrel, embedded in the nose, that I have heard of, weighing 3 oz. in the breech and ½ oz. in the bolt, the former having dimensions of 2⅞ by 1⅛ by ¾ in., and the latter 2¼ by ¼ in. The next largest that I know of is that removed by Mr. George Lawson, depicted in the second and subsequent editions of his work on the Eye, and weighing 1½ oz.

Liverpool.

LATERAL DEVIATION OF THE SPINE.

BY F. R. FISHER, F.R.C.S. ENG.
SENIOR SURGEON TO THE NATIONAL ORTHOPÆDIC HOSPITAL.

THE various conditions of curvature of the spine have of late years attracted a considerable degree of attention, especially with reference to their treatment. Pott's disease of the spine, or, as it is more commonly called, "angular deformity," and lateral curvature, have mainly, it might perhaps be written solely, received notice. Concerning these deformities more difference of opinion has been expressed as to the most desirable methods of treatment to adopt for the relief of the latter than of the former condition, because most surgeons are fairly well agreed as to the objects to be striven for in order to relieve Pott's disease, whilst they dispute pretty freely as to what lines should be followed to overcome lateral deformity. Much of this difference of opinion is to be traced to a confusing together of several conditions of lateral deviation of the spine under the one term lateral curvature. Now, although lateral curvature varies greatly in its nature, especially as regards the situation of distortion and the number and length of the curves formed in the column, there is one distinguishing feature in this deformity which should prevent any error in diagnosis, and to this point alone need reference be made here. Wherever the curves may be situated, whether in the cervical, dorsal, or lumbar region of the spine, whether in the early or late stage of the deformity, there will always be found that condition which has given to lateral curvature of the spine the name of scoliosis; this ever present characteristic is the so-called "rotation of the vertebræ"—that is to say, the anterior portion of the column, the bodies of the vertebræ, is further displaced from the median line than is the posterior portion, the spinous processes; indeed deviation of the latter processes is frequently

not established until very considerable displacement of the bodies of the vertebræ has taken place. From the presence of this structural change in the column it follows that in whatever position the subject of the deformity is placed the distortion of the spine remains, a fact in itself of great aid in arriving at a correct diagnosis of the condition. A surer and equally simple mode by which to detect lateral curvature is to make the patient stand erect in the drill position of attention, and gradually stoop forwards as though endeavouring to accomplish the familiar feat of touching the toes with the tips of the fingers without bending the knees; if whilst the patient is in this position, with the pelvis nearly at right angles with the thighs, the surgeon runs his fingers down the column, one on either side of the spinous processes, there will be detected a fulness at the seat of curvature on the side towards which the transverse processes of the rotated vertebræ are directed backwards, whilst a groove, owing to the same processes being thrown forwards, will be distinctly evidenced on the opposite side.

The fact that lateral deviation of the spine does not constitute lateral curvature cannot be too strongly insisted upon. Once arrive at a clear understanding on this point and much controversy might be avoided. To illustrate the confusion which at present exists between the various conditions of lateral deflection there are here figured three cases, showing marked deformity of the spinal column, all of which were described as cases of lateral curvature. In only one of these cases was there any evidence of rotation of the vertebræ, and where this condition did exist it had been overlooked and that portion of the spine had been regarded as perfectly normal. An interesting point to observe about these cases is that they present a marked similarity to one another in external appearance. Fig. 1 might be regarded as the advanced stage of the same condition existing in Figs. 2 and 3; nevertheless they all distinctly differ in their nature.

FIG. 1.

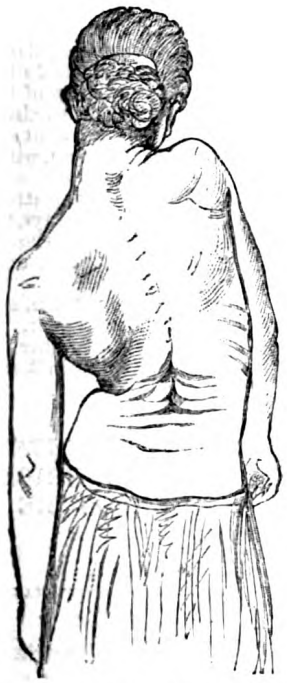

FIG. 2.

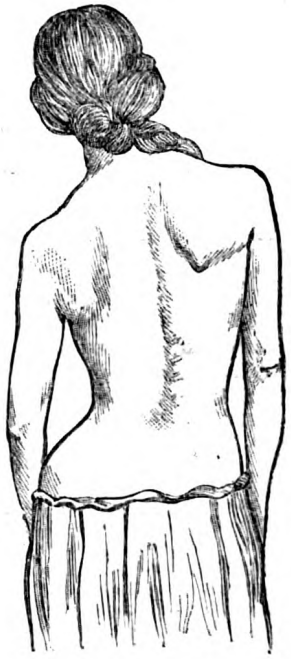
FIG. 3.



The case shown in Fig. 1 was a girl aged nineteen, who had been for a long period under treatment for lateral curvature; as will be seen, she presented a terrible condition of deformity when standing erect, but when lying down the spine was perfectly straight; moreover, she could, by placing the hands on the hips, herself force up the column, and so extend it almost to the normal shape; there was here, then, no structural change in the spine of any sort. This case belongs to a class of which examples are constantly to be met with, and to which, to distinguish them from true lateral curvature, the term *lateral bending* might very well be applied. The subjects are usually young girls who are overworked and underfed, the servant of the lower classes, girls educated at cheap "establishments for young ladies," the attendants at second-rate drapery shops, and such like; also it is met with in those who have suffered from long illness of an exhausting nature, and in those affected with that defective condition of health commonly described as general debility. Frequently accompanying the deformity, as it did in this case, is that mental condition which tends to exaggerate any bodily derangement; the hysterical complication generally appears at a late, and not an early, stage of the affection, which must not be confounded with the so-called "hysterical spine."

The case illustrated in Fig. 2 was one of a remarkable nature. It is well known that Pott's disease sometimes gives rise to lateral distortion; when this occurs it is usually in the advanced stage of the disease, and is caused by one or more vertebræ being so affected that the sides of the bodies are chiefly destroyed, instead of the anterior portions, as usually happens. In the case of the girl here figured, however, lateral deviation was one of the first symptoms of Pott's disease. A few days after the patient first came under my notice local pain was complained of in the spine, at about the situation of the second lumbar vertebra. On examination, I found that there was some slight rigidity of the spine at this point, and complete recumbency was ordered to be observed. In a few weeks slight prominence of the second lumbar vertebra was well marked, and the case clearly declared itself to be one of Pott's disease of the spine. Probably such a state of things as here existed is of very rare occurrence, and it is to be hoped that it is so, for such a condition might very well be mistaken, when in its earliest stage, for the comparatively trifling affection of lateral bending of the spine. Under no circumstances, however, should such a case be mistaken for one of lateral curvature, and yet as such was it described by a surgeon who has written somewhat freely on the subject of deformity of the spinal column.

The third case was a young girl, aged seventeen (Fig. 3), who was sent to me as requiring treatment for lateral curvature in the dorsal region of the spine. For the relief of this she had been wearing for some months a plaster-of-Paris jacket, and had been kept almost entirely recumbent; the deformity continued to increase, and her general health began rapidly to fail. When I first saw her she could only walk a few steps, her muscles were soft and flabby, and she was very thin; with regard to the existing deformity of the spine, that which was most evident when she was standing up (the lateral deviation in the dorsal region) disappeared

when she lay down, but well-marked rotation of the vertebræ in the lumbar region was present, although the spinous processes were not out of the straight line. A few weeks' care restored the general health and overcame the lateral bending of the spine in the upper part of the column, the rotation of the vertebræ in the lumbar region was afterwards reduced, and she made a complete recovery.

On the question of distinguishing such cases as have here been described as lateral bending of the spine from those of true lateral curvature, regard must be paid to the fact that many authorities describe lateral curvature as presenting in the early stage only lateral deviation of the column unaccompanied by rotation of the vertebræ, and the latter complication is given as a later phase of true lateral curvature. Without questioning the correctness of this view, at the same time not admitting its truth, it is sufficient here to indicate the reason for regretting such a method of description; granting, then, that lateral bending may terminate in lateral curvature, the latter term should not be applied until the deformity is accompanied with rotation of the vertebræ, because this is the essential characteristic of the affection. Every surgeon must admit that lateral deviation of the spine may arise and disappear without any structural change in the spinal column becoming developed; we are therefore no more justified in describing lateral bending of the spine as lateral curvature than we should be in calling pleurisy empyema, or periostitis necrosis, simply because the one disease may precede the other. To enter more fully upon this subject would necessitate a consideration of the etiology and pathology of lateral curvature, matters upon which the writer hopes to treat in another communication.

Grosvenor-street, W.

SCLERODERMA IN RELATION TO FILARIA SANGUINIS HOMINIS.

BY JOSEPH BANCROFT, M.D.

ON May 4th, 1883, a case of scleroderma came under my notice in the person of a colonial-bred girl who had resided most of her life near the town of Ipswich, and on examining her blood I discovered filariæ in abundance. I have had this patient under observation since that time, and thinking I might find additional evidence of the association of filariæ with scleroderma I delayed making the communication until the present time. As no other cases of scleroderma can be found in the limited population of this colony (the filaria diseases being happily on the decrease by better attention being paid to securing pure drinking water), I considered it best to make my experience public in order to inform observers in South America and Asia of this case, so that in their wider fields of observation it may be possible to pursue the inquiry further.

My patient is seventeen years of age, and has been attacked with a thickening and hardening of the skin of the face, arms, shoulders, and all the body above the level of the waist. Below this part the integument is softer, and is normal over the legs. The skin feels like salted ham, it is impossible to pinch up a fold of it, and the sensation in it is but little impaired. No folds or creases are to be seen on the face, neck, or other parts down to the level mentioned. She does not complain of dyspnœa, though the textures of the chest seem so inflexible. I thought I had seen a similar case before, the patient being Captain B——, a Dane, a Sandwich Island trader, who had in April, 1875, come to live here for the benefit of his health, but in his case the skin was more flexible. I examined his blood then, with negative results. Photographs of the girl suffering from scleroderma were taken on May 15th, 1883. About the end of the same month she was taken ill with symptoms like peritonitis, from which she recovered. Some time later I sent for her, to show the blood to a Mauritius medical practitioner on a visit here, but could find no filariæ. Months later I examined her before Professor Anderson Stewart of the Sydney University, when the microscopic worms were demonstrated active and abundant. In the work of the late Tilbury Fox, page 345, is quoted the opinion of Rasmussen, that scleroderma is of elephantoid nature, and that observer suggested the name "elephantiasis sclerosa" for it. In Quain's Dictionary, published this year, is an article by the late Erasmus Wilson, which gives no recent observations on this curious disease. I have no doubt the scleroderma of this kind is correctly interpreted by Rasmussen as a form of elephantiasis of the upper parts of the body. How the lymphatics in elephantiasis become obstructed by adult filariæ will require some careful injections and dissections of those vessels to determine. In old cases of elephantiasis of the legs and scrotum the microscopic filariæ are seldom found in the blood, due possibly to death and calcification of the adult worms. The parent worms may not live in the lymphatic ducts at all for anything we know to the contrary, but by their proximity to these vessels and by their penetrating them to void their brood, inflammatory closure of the larger lymphatics may ensue. The sexual orifice of the mother-worm pointed out by Dr. Cobbold, and figured in THE LANCET as close to the head of the animal, is a fact to be carefully noted. The Sandwich Island patient probably had suffered from filariæ. No microscopic brood could be found in his blood when he lived here. He suffered from strange pains in his chest like angina, seldom could lie down and rest for long together. He took large doses of morphia with very little relief. I lost sight of him after about a year's observation, and he died later on while travelling for his health.

The patient, S. J——, aged seventeen, of German parentage, was born in Ipswich, Queensland, and lived for the first six years of her life in a neighbouring farming district, the Walloon Scrub, since which she has lived eight years in Brisbane. She has always enjoyed good health and went to school until twelve years of age. She has drunk water without care as to boiling or filtration. She occasionally shivers for a few seconds, eats well, bowels act regularly, menstruates scantily, is not short of breath, and can do her housework. She wishes to be cured of the hardness of the face, arms, and upper parts of the body, which has existed four months, and came on almost imperceptibly, without any sickness. This hardness is, as above described, uniform, without creases, and the skin cannot be pinched up. Filariæ were found in abundance on May 4th, 1883. In June, after an attack of mild peritonitis, which kept her in bed for some days, the microscopic worms could not be found in the blood, though examined with a plentiful supply and with great care. Later in the year they were found in abundance.

Dec. 1884. She is working as housemaid near town, and has not been under medical treatment for the past year.

I trust that the history of this case will lead to further inquiries by Drs. Manson and Lewis and by practitioners in Brazil.

Brisbane.

CASE OF SCARLET FEVER WITH EXTENSIVE SLOUGHING OF LEFT ANTERIOR TRIANGLE OF NECK AND EXPOSURE OF VESSELS.

BY A. GLOVER WILLIAMS, M.R.C.S.,
SURGEON TO THE BRIXTON DISPENSARY, LATE HOUSE-PHYSICIAN ROYAL HOSPITAL FOR DISEASES OF THE CHEST.

ON Oct. 23rd, 1883, a boy aged six years was brought to me by his mother. He was delicate-looking, of fair complexion, with light hair. He had been for the last two or three days suffering from sore-throat, accompanied by feverish symptoms, but no rash, according to his mother's statement. On examination, there was slight ulceration of both tonsils; the glands at the angles of the jaw and along the inner edges of the sterno-mastoid muscles were enlarged and painful, especially on the left side; there was some amount of fever, but no sign of any rash or desquamation. The patient was ordered to be kept at home. When I visited him on the 25th there were the same symptoms, but the fever was more marked. Temperature 102° F. No rash was to be found on examination. By the 28th the throat symptoms had much increased; there was marked ulceration of the tonsils; the glands at the angle of the left jaw and along the inner edge of the sterno-mastoid were much enlarged and tender, but not fluctuating. I ordered chlorate of potash and bark.

On November 3rd the ulceration had extended over the fauces, palate, and tongue, but did not involve these structures to any depth. Temperature was 103°. On the 5th the throat symptoms were about the same; the glands on the left side were now semi-fluctuating. On the 7th I opened the abscess, but only a small quantity of pus came

away. The next day the skin over the glands sloughed, exposing a space corresponding on the outer side to the inner edge of the left sterno-mastoid muscle, on the inner to the middle line of the neck, above to a line drawn from the angle of the left jaw to the upper border of the thyroid cartilage, and below to a line drawn on a level with the lower edge of the cricoid cartilage. The vessels were plainly seen in their sheath, the superior thyroid artery crossing the space. After syringing the cavity out with Condy's fluid and water, it looked as clean as if it had been dissected; it was dressed with iodoform. Port wine was ordered. On the following day there was no extension of sloughing. Pulse 112, rather feeble; temperature 101°. The ulceration of the fauces, tongue, &c., was rather better. The cavity was washed out and dressed with iodoform. On the 14th the cavity was granulating and closing; still syringed and dressed with iodoform. General condition fairly good; pulse still rather feeble; temperature 99°. On the 18th the fauces and tongue were much improved; cavity still closing and general condition improving. Ordered a mixture of perchloride of iron and cod-liver oil. After this the patient went on uninterruptedly well, the cavity gradually got smaller, and by the third week in December was completely healed, leaving only a scar one inch and a quarter long and half an inch wide, with no tendency to contraction, all the movements of the neck being perfectly performed. In conclusion, there was distinct peeling, which was noted a few days after he came under my care. He had no albumen in his urine at any time during his illness.

Remarks.—The interesting features in this case are the facts—first, of his recovery; and, secondly, the perfection of the repair of the parts after so great a destruction of tissue. Two cases occurred in the practice of a friend, when after the sloughing the temperature still remained very high, showing probably that the sloughing was only a local manifestation of a general high state of blood-poisoning. Oozing of blood from the ulcerated surface was the cause of death in another case that came under my notice. The oozing was general, no large vessel being involved. As regards the opening of the abscess in these cases, I am inclined to think that if sloughing is likely to take place, it will do so whether an opening is made or not. The diet consisted of beef-tea, essence of beef, milk and eggs beaten up, and during the greater part of the illness two ounces of port wine daily.

ST. GEORGE'S HOSPITAL.

STRANGULATED UMBILICAL HERNIA; OPERATION; RADICAL CURE; RECOVERY; REMARKS.

(Under the care of Mr. T. P. PICK.)

THE operation for strangulated umbilical hernia was formerly looked upon as one of the most serious in surgery, the result being so often fatal. Since the introduction of the antiseptic treatment, however, although no surgeon would lightly undertake the operation, still he is able to do so with far greater confidence and hope of success, and is less inclined to allow valuable time to be wasted in trying other treatment of doubtful utility. The plan adopted by Mr. Pick in this case will probably be frequently imitated by many in future operations of a like character.

We are indebted for the following notes to Mr. Herbert Allingham, late house-surgeon.

Catherine C——, aged fifty-three, married; has had seven children. She had suffered for six or seven years from mitral disease, and was an in-patient in 1879 under the care of the late Dr. Barclay. While in the hospital she was tapped, and a large quantity of ascitic fluid drawn off; she remained in nine weeks. In June, 1884, she was again admitted for a month, this time not being tapped. The hernia for which she had come to the hospital on Dec. 9th had existed for eight months. On Monday, Dec. 8th, she caught a severe cold and cough, the latter being very troublesome. She removed the bandage which kept up the hernia in order to apply a poultice to the front of her chest. While the bandage was off she was attacked with a violent fit of coughing, causing the intestines to protrude at the umbilicus. She then tried to reduce the hernia, but failing, put on the flannel bandage and went to bed. The next day she began to vomit and complained of much abdominal pain, so sent for a doctor, who ordered an enema of castor oil and a purge. After this her bowels acted twice, but the vomiting still continued and became very feculent. On Wednesday, the third day after strangulation commenced, she was brought to the hospital in the following condition. About the umbilicus was a tumour three inches in diameter, tender, tense, with the skin over it red and œdematous; no impulse on coughing; the rest of the abdomen being distended with a large quantity of ascitic fluid; tongue brown and dry; pulse small and rapid. While in hospital she vomited three times before the operation. Mr. Pick was immediately sent for, and operated, the patient being narcotised with ether, which she took very well. An incision was made over the tumour about three inches in length, and the sac, on being opened, was found to contain a good deal of fluid, with flakes of lymph in it. The intestine presented the following appearance—viz., very congested and covered with recent lymph, part of it being quite discoloured and of a greenish hue. As much as possible of the lymph was wiped away. Mr. Pick then incised the ring and reduced the hernia, emptying out of the abdomen about two quarts of ascitic fluid. The edges of the ring were then pared all round, and brought together with four silver sutures; a small piece of drainage-tube was then inserted into the sac, and the edges of the skin approximated with sutures over the closed abdominal aperture, the wound being dressed antiseptically with carbolic gauze. The same night she vomited once, the matter being feculent. The bowels acted twice. She was ordered some opium and ether mixture, and later on in the evening three ounces of brandy.

11th.—Morning temperature, 99°; evening, 99·6°. Pulse, morning, 108; evening, 110. Bowels acted twice; tongue rather dry and yellow. Patient inclined to sleep. Complained of a little pain in the abdomen, but slight tenderness and no distension. Cough troublesome.

12th.—Morning temperature normal; evening, 98°. Pulse, morning, 104; evening, 96. Bowels acted twice; no vomiting. Tongue moist and coated. No pain in abdomen. Still cough.

13th and 14th.—About the same temperature, normal night and morning. On the 13th bowels acted twice. Still only taking strong beef-tea and milk.

15th.—Temperature normal. Tongue moist and clear. Pulse 90. Bowels acted once. No pain, distension, or tenderness of abdomen. Cough much better.

17th.—The wound was dressed, only some serous discharge. Superficial wound healing, the track of the drainage-tube was gently syringed out, and the tube discontinued. No pain or tenderness about the abdomen, it being quite soft. The wound was dressed again antiseptically. Temperature and pulse normal.

25th.—Again dressed and superficial stitches removed. Wound nearly healed over sutures, bringing the peritoneal edges together. Wound dressed in the same way. Temperature normal; cough gone. Sleeps and eats well. Fish diet, one pint of milk and an egg daily.

30th.—Antiseptics discontinued; wound now only covered with zinc ointment.

Jan. 2nd.—She got up, lying outside her bed; wound was healed. Patient wearing an abdominal belt.

14th.—Left the hospital well.

Remarks.—There are two points probably worthy of notice in this case. First, in consequence of the chronic ascites the peritoneum was less inclined to take on active inflammation; second, as Mr. Bryant has shown, operating on this kind of hernia is extremely fatal when the sac is opened, but if the stricture can be relieved without opening the sac and the intestine reduced, there is a much better chance of recovery. Therefore, in umbilical hernia where it is necessary to open the sac, it would seem advisable to do as Mr. Pick did in this case viz., to pare the edges of the ring and bring them into close apposition so as to obtain rapid closure of the abdominal aperture, which will prevent extension of inflammation from the superficial wound, or drainage of exudation into the abdominal cavity.

LEEDS FEVER HOSPITAL.

DEATH AFTER THE USE OF ANTIPYRIN; NECROPSY; REMARKS.

(Under the care of Dr. BARRS.)

ANTIPYRIN is one of those remedies which will probably take a prominent place in the materia medica of the future, and it is therefore the more necessary to publish cases where untoward results have followed its use. As a rule, it appears to be a drug the administration of which is not followed by unpleasant symptoms, though vomiting, a peculiar exanthematous rash, resembling measles, and, as in the case referred to by Mr. Blore in his remarks, collapse, have followed its use. Antipyrin is a very valuable means of reducing the temperature and the frequency of pulse and respiration in fevers and febrile diseases, the effect being prolonged from ten to twenty hours. It does not, however, appear to act as an antiperiodic. Chemically it is described as dimethyl-chinizin, and is stated by Dr. Knorr of Erlangen to be one of a series of derivatives from a hypothetical base, to which he has given the name "chinizin." The chinizin derivatives are products of the action of diacetic ether upon one of the hydrazines. For valuable information about this drug, we would refer our readers to the *Pharmaceutical Journal*, Nov. 1st, 1884, and to the *Therapeutic Gazette*, Oct. 1884 and Jan. 1885. See also *Berichte* (xvii., 2032), *Wiener Med. Blätter; Prager Med. Wochenschrift*, Oct. 1884; *Schmidt's Jahrbücher*, 1884, p. 127; *Bulletin Générale de Thér.*, Oct. 1884.

For the report of this case we are indebted to Mr. Blore, resident medical officer.

H. M——, aged thirty-five years, was admitted on Jan. 15th, 1885, with the following history. On Dec. 4th, 1884, the patient had a miscarriage in the fifth month of pregnancy. From that date to the day of admission (six weeks) she had been confined to bed. Soon after the miscarriage she suffered from pain in the lower part of the abdomen, vomiting, headache, and shivering; and, later on, from diarrhœa. She became progressively weaker, but never lost consciousness. She was kept on milk diet, and the vagina was syringed. She was sent to the hospital as a case of enteric fever.

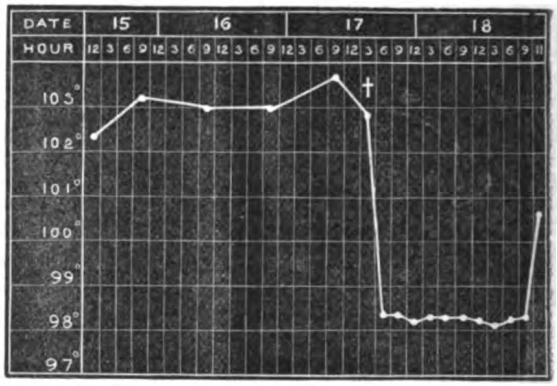
On admission, the patient was intelligent, and she gave the above short history of her illness. She was very weak, turning in bed with difficulty, but had not lost much flesh, and did not appear to be suffering any acute pain. The pulse was regular, but somewhat small and compressible; heart sounds quite free from bruit; pulmonary signs normal. The tongue was moist and only slightly furred, abdomen little, if at all, distended, and tender on pressure, the tenderness not localised to the ileo-cæcal region. No splenic enlargement was detected. There was no evidence of an enlarged uterus, no vaginal discharge, and the os uteri was closed and normally placed and directed. The temperature was 102·4°. The length of the illness, the course of which seemed to have been uninterrupted, its commencement with a miscarriage, and the absence of any signs distinctly pointing to enteric fever, led to the case being regarded as probably of a puerperal nature, but no exact diagnosis beyond the negation of enteric fever was made. In the evening of the day of admission the temperature rose to 103·2°.

Jan. 16th.—Slept during most of the night. General condition appears much the same as on admission. Temperature 103°; pulse 120, and in no way improved; tongue covered with thin white fur; abdomen only slightly tender. No complaint, except of weakness; no action of bowels. To have enema, and to take five grains of quinine three times a day. Evening temperature 103°.

17th.—Patient has passed a restless night, with little sleep. Temperature 103·6°; pulse 132; respiration 36. Is quite rational; tongue and abdominal signs not appreciably changed, but bowels have acted twice normally, enema not being required. The quinine was stopped, and, to reduce the temperature without causing further depression, thirty-five grains of antipyrin were administered at 3 P.M., followed three hours later by half that quantity. The temperature, taken at 3 P.M., was nearly 103°; pulse 132, and very feeble. At 6 P.M. the temperature was 98·4°; pulse 108; skin cool and moist. At 11 P.M. the rectal temperature was 98·4°; pulse 132. Patient answers questions intelligently and makes known her wants, is pale and still, and, except for rapid feeble pulse, her condition appears much as it did five hours ago. Temperature 98°.

18th.—Restless night, with some diarrhœa and vomiting; skin pale, cool, perspiring; rectal temperature 98°; pulse 120; respiration sniffing in character; is intelligent and makes no complaint, but is much collapsed. To have half an ounce of brandy every two hours. 5 P.M.: No reaction; hot bottles, &c., applied. 9 P.M.: Pulse much worse than four hours ago. Patient now lethargic; skin cold and perspiring; heart sounds muffled; respiration shallow and sniffing; some râles at bases of lungs. Increased efforts at stimulation by means of brandy and ammonia and turpentine to chest were to no purpose, the patient dying at 11 P.M., thirty-two hours after taking the antipyrin. The temperature rose to 100·6° during the last half hour of life.

The accompanying chart shows clearly the rapid fall and prolonged low temperature, the † marking the point at which the drug was administered.



The following is briefly the result of an examination made the day after death:—Brain and its membranes much congested, the superficial veins being especially dilated, with a few hæmorrhages. Pericardium normal, heart free from valvular disease, but somewhat softened; a few old adhesions of the pleuræ, but no excess of fluid. Lungs much congested, but otherwise normal. No peritonitis. Liver normal. Spleen much enlarged, weighing 3 lb., and softened. Its middle third was occupied by a large infarct, broken down into a cavity in the centre. Kidneys also enlarged, and each contained two or three conical infarcts. Intestines intact in their whole length. Uterus contracted and empty.

Remarks by Mr. BLORE.—The chief interest in the above case lies in the effect of the antipyrin. From the day of admission to the time of taking the drug there had been uniformly a high temperature. Within three hours the temperature had become normal, or subnormal, and did not subsequently rise until the patient was actually dying. It is recommended by those who have had most experience of the drug that thirty grains be given as often as every hour for three doses, or a single dose of sixty grains, in either case much more than the patient in question took. In the case of other adult patients here, single doses of twenty or thirty grains have produced only a temporary remission, the temperature having resumed its former height within four hours. It was with the view of preventing this rise that the second smaller dose was ordered to be given three hours after the first. This object was certainly effected, but unfortunately no improvement, but the reverse, took place in the other symptoms, and collapse ensued. The chief attribute urged in favour of antipyrin is that dangerous symptoms never follow its use. May alone (*Deutsche Med. Woch.*, 1884) mentions a case of collapse after antipyrin, but is uncertain whether to attribute the collapse to the drug or to the course of the disease. In the case above described, though the patient was undoubtedly very ill, there can be no question that the extreme depression, accompanying the fall of temperature, was directly due to the action of the drug.

SUNDERLAND INFIRMARY.

CASE OF TRAUMATIC TETANUS; RECOVERY.

(Under the care of Dr. JAMES MURPHY.)

J. S——, a lad aged fifteen, was admitted on Sept. 24th, under the care of Dr. Murphy, with well-marked symptoms of acute tetanus. The following history was obtained:—Twenty days previous to admission the terminal phalanx

of his left thumb had been severely crushed and bled freely, but there was no fracture of the bone. He was treated by Dr. Shelley with an astringent lotion, but the wound showed no sign of healing, and after a week presented a very foul greyish appearance, as if a fungus were growing on it. During this time he felt well, and was running about, but four days previous to admission he felt very languid and had a general feeling of malaise, which was soon followed by stiffness of the muscles of mastication and of the face generally and neck. This condition rapidly spread to the muscles of the limbs and trunk, and when admitted the risus sardonicus was particularly well marked, the under jaw protruding and fixed so that the tongue, which was thickly coated, could but with difficulty be passed between the teeth. The muscles of the trunk and limbs were very rigid, and opisthotonos well marked, the lad resting on his heels and occiput, and every few minutes a violent and characteristic spasm of the voluntary muscles would seize him, which would soon cease completely and leave him perfectly still. These attacks would be sometimes delayed as long as half an hour if nothing disturbed him; but the opening of a door, or speaking to him, brought them on at once. On placing the hand on his abdomen it felt like a board. His wrists and ankles were quite movable, and were not affected at any period of the attack. He complained of great pain in his thighs, similar, but much more severe in character, to ordinary cramps. His pupils were normal; his eyes generally closed. He never spoke except when asked a question, and then replied as laconically as possible. His intellect was quite clear, and his temperature 100°. He was at once given a calomel and jalap purge, as his bowels had not been open for several days, and placed in a small private ward, which was regularly kept at a temperature of 65°, and though there was no apparent draught, the bed was carefully surrounded by large screens, and he was placed on twenty grains of chloral and thirty of bromide of potassium, to be administered every three hours, day and night. What milk he could swallow, with great difficulty, was allowed him, and he had nutrient enemata of beef-tea and eggs. The whole of the terminal phalanx of the injured thumb was amputated shortly after his admission. Within twenty-four hours the spasms had ceased very considerably, and now only recurred at an interval of an hour or two, and were much less severe in character. The temperature sank to normal. The case progressed day by day to complete recovery about the twentieth day after admission. The progress towards recovery was well marked during the first forty-eight hours, after which the symptoms were but slight, and gradually passed away. First the spasms disappeared, then he could open his mouth a little more, next the pain in the thighs was not so distressing; the opisthotonos became less marked; then the risus sardonicus slowly faded away; the rigidity disappeared, and he completely recovered; the temperature having varied from 101° to 98° without any apparent cause. The amputated phalanx was examined, but without any definite result.

Dr. Murphy attributes the satisfactory result not to any one part of the treatment, but to the whole of it. First, the removal of the irritating wound, then the free use of chloral and bromide of potassium, to control the spasms, which he regards as of great consequence, so as to guard against the consequent exhaustion, and for the same reason the isolation of the patient in a small private ward, where the temperature was kept at 65° without varying, and the bed carefully protected from all draught by large screens, and, finally, the judicious administration of plenty of nourishing food by mouth and rectum.

MEDICAL SOCIETY OF LONDON. — The following is the list of names of Fellows of the Society nominated for office by the Council for the ensuing year:—President: W. M. Ord, M.D. Vice-presidents: R. D. Powell, M.D.; Sydney Jones; J. L. Down, M.D.; S. Cartwright. Treasurer: A. E. Durham. Librarian: W. H. Allchin. Hon. Secretaries: J. K. Fowler, M.D.; J. H. Morgan, M.A. Secretary for Foreign Correspondence: Felix Semon, M.D. Council: T. L. Brunton, M.D., F.R.S.; S. H. Davson, M.D.; Sir Joseph Fayrer; D. W. Finlay, M.D.; A. P. Gould; F. de Havilland Hall, M.D.; Francis Mason; Edmund Owen; Isambard Owen; G. R. T. Phillips; T. Pickering Pick; W. Pye; J. P. Richards; A. E. Sansom, M.D.; C. B. Sewell, M.D.; W. H. Strange, M.D.; T. T. Whipping-ham, M.B.; W. H. White; C. T. Williams; A. Wiltshire, M.D.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Hereditary Locomotor Ataxy.—Fatal Hæmoptysis.

AN ordinary meeting of this Society was held on Tuesday last, Dr. George Johnson, F.R.S., in the chair. The papers read were decidedly interesting, and excited a fair amount of discussion.

Dr. J. A. ORMEROD read a paper on Hereditary Locomotor Ataxy. The first part of the paper dealt with the differential diagnosis of hereditary ataxy and ordinary tabes dorsalis. The symptoms which distinguish the so-called hereditary ataxy from ordinary tabes dorsalis were said to be: (1) The occurrence of the disease in many members of one family; (2) its onset in early life; (3) the absence at first of pain, or any other of the multiform symptoms of tabes; and (4) the occurrence later in the disease of disorder of speech and of nystagmus. The second portion of the paper dealt with the clinical histories of cases of hereditary ataxy. The clinical history of a family of seven children, of whom three were ataxic, was given. The mother had had fits, the mother's sister was insane, and her father was probably ataxic. The first case was that of a girl in whom the onset was accompanied by choreic movements. There was unsteadiness in walking, increasing till she now could not stand alone; there were occasional fainting fits and some muscular weakness of the legs, with rigidity at the ankles and club-feet of the equinus variety. The second case was that of a boy of the same family, and the unsteadiness of gait slowly increased; he had had a few attacks of giddiness, and there was a slight affection of the speech. The third case was that of a young woman, in whom the onset was much the same as that in the first case; in addition, lateral curvature of spine, slight ptosis, and occasional squint were present. The next family was one of nine children; no nervous disease could be discovered in the parents or grandparents; of this family, three, or possibly four, members were ataxic. One of these was a female aged twenty; unsteadiness of gait set in at the age of thirteen, and had been worse since a "low fever" two years ago. She was now unable to walk without support; there were slight muscular weakness in the legs, shooting pains last year, and speech was doubtfully affected. The fifth case was that of a female aged sixteen. The case was similar to that of her sister, but less advanced; there was no muscular weakness or pains. There were anæmia and attacks of headache, with vomiting. The knee-jerk was absent in all four cases, and apparently in some other members of the family as well. The author made some remarks on the etiology of the disease. Other nervous diseases—colour blindness, hæmophilia, diabetes insipidus—which attack families were compared with this disease, and other factors which might assist in the development of the disease were remarked upon, and more especially puberty and acute diseases. Friedreich's disease did not appear to be propagated through the female parent. Several living specimens of the disease were exhibited before the meeting commenced.—Dr. ALTHAUS thought Dr. Ormerod's paper was a valuable contribution to our knowledge of a disease of which but little accurate information was forthcoming. In this so-called hereditary ataxy there was no actual hereditary influence to be observed. The pathological lesions were of a much more diffuse character than was usually found in cases of ordinary tabes dorsalis. In Friedreich's disease the grey matter and lateral columns, and even the anterior columns, may be affected with the sclerosis. Disorders of a sensory kind were not met with in the early stages of the "hereditary ataxy." The individual history of cases of tabes dorsalis was all important, and the history of the stock from which the patient came had nothing to do with the etiology. The clinical symptoms of locomotor ataxy had not been recognised for as long as four generations. Alcoholism of the parent, and especially of the father, was probably causative in Friedreich's disease.—Dr. BUZZARD said that he concurred in the view that this apparently rare disease was very different from the ordinary progressive locomotor ataxy of which we saw so much. He considered that we constantly failed to see what we did not look for, and could not help thinking that these cases were more numerous than we thought. The absence of

sensorial symptoms was noteworthy; it was the motor side which was almost exclusively affected. In a recent case which came under his notice there had been acute disease, which no doubt aided in the development of the symptoms. He should agree with the view that this form of ataxy was not strictly hereditary. But with regard to true tabes dorsalis, he was not so sure that this did not occur in families. From his experience he considered that there might be some peculiar family proclivity to tabes dorsalis. A point which had not been referred to in regard to Friedreich's disease was the importance of its diagnosis from cases of hysteria, especially at the present time. Reference was made to a case which he had seen with Dr. Playfair of supposed hysteria, which had been sent to that gentleman to be treated by the Weir Mitchell method. The patient was a young lady, aged twenty-six, of hysterical manner. It was alleged that she could not stand; she fell in a "heap" on the floor when attempts to stand were made. The arms were affected with distinctly ataxic movements. Such symptoms might occur without any organic disease whatever being present. This patient had a prodigious lateral curvature of the spine; there were no sensorial symptoms, not even anæsthesia. The reflex from the sole of the foot was perfect. She had no pain. There was no knee-jerk in either leg. The speech was of a marked "toxic" character. At times considerable urgency, not to say force, had been employed to induce her to walk, and a certain amount of unintentional harshness had thus been used towards her. There was no history of any other case of the kind in the family. When the child was only five or six years of age she was noticed to tumble, and was supposed to be careless. At the age of eight or ten, whilst learning to dance, she frequently fell down without apparent cause. At twelve years of age she had taken a long walk for the last time. At the age of seventeen there was great weakness of the legs. Three years ago she suffered from typhoid fever, and since then had been unable to stand. These cases were important to be borne in mind when the question of hysteria came before us. For this simple practical point alone we ought to be indebted to Dr. Ormerod for his valuable paper. Mr. R. W. PARKER asked whether these patients were suckled or not; it might be that rickets had something to do with the causation of the disease.—Dr. K. FOWLER gave a few details of a family of well-to-do people of whom two boys and one girl were affected. The ages of the boys were fourteen and five, and that of the girl nine. In each case the disease had followed very much the course described by Friedreich. No acute disease had preceded the onset of the malady. There were no lightning pains. The pupils were normal. The mother was healthy; the father was of intemperate habits, and died of cancer. In one of the boys there were marked erotic tendencies at an early age, and he had lately had marked lightning pains. In the girl there was some wasting of the leg. The knee-jerks were absent, and the ataxic gait was very marked in all the cases. There were two more members of this family, both girls, one aged twenty and the other seventeen; the latter had slight ataxic symptoms, the former was healthy.—Dr. ORMEROD, in reply, said it was difficult to investigate the question of heredity, for many reasons. In a third family of whom he had read in an Italian paper the great-uncle was ataxic. He had seen a fourth family of two boys, both of whom were ataxic. The mother, and possibly the mother's father, had had a somewhat similar disease to that of the boys. With regard to the morbid anatomy, the posterior column was sclerosed throughout, and deeply. The question of hysteria might crop up frequently. Ataxic patients might easily be accused of intemperate habits.

Dr. SAMUEL WEST read a paper on Fatal Hæmoptysis, which dealt with the statistics of the last fifteen years of the Chest Hospital, Victoria-park. Some remarks were made on Profuse Hæmoptysis which was not fatal. These statistics were confined to hæmoptysis in the limited sense of the term, and all cases were excluded which were due to the rupture of one of the large arteries, other than the pulmonary, into the trachea or bronchi, or through the lung, as in the course of thoracic aneurysm or new growth. The cases were twenty-six in number, of which twenty were males and six females. There was no special liability at any age. Men were more frequently attacked than women, in the proportion of about three to one. Chronic phthisis was the predisposing condition of the lung, and that was often the case where there were but few clinical evidences of the disease. Fatal hæmoptysis was rare in subacute cases of phthisis, and perhaps never occurred in acute phthisis. The cause was ascertained in seventeen out of twenty-five cases. In eleven it was aneurysm, and in six ulcerated vessel. The distinction between aneurysm and ulcerated vessel was probably only one of degree. The site of the lesion was generally the left artery, about twice as often as the right one. The source of the hæmorrhage was not necessarily found on the most affected side of the chest or in the most affected part of the lung. Any cavity, whatever its origin or shape, might be the source of the hæmorrhage provided the cavity be of the chronic order. The favourite seat was in the middle of the lung near the periphery. Certain facts about pulmonary aneurysms with regard to size, origin, shape, number, contents, rupture, &c., were referred to and the pathology discussed. The causes of non-fatal cases and of fatal cases of hæmoptysis were probably the same, there being evidence to show that both pulmonary aneurysms and eroded vessels may heal spontaneously.—Dr. PERCY KIDD showed a specimen of multiple aneurysms of the pulmonary artery in the lung, and also an aneurysm on the outside of which was laminated clot. He said that during the past two years and a half he had had thirty-five fatal cases of hæmoptysis; thirty were immediately fatal, five indirectly fatal from exhaustion in the course of from thirty minutes to twenty hours. In thirty cases there was rupture of an aneurysm. In one case an ulceration of the bronchial wall had extended into a branch of the pulmonary artery; in another case the separation of hydatid membrane from the cavity of a lung caused the hæmorrhage; in one case an unruptured aneurysm was found. In many cases of aneurysm of the pulmonary artery there was no marked history of hæmoptysis, and he had brought before the Pathological Society cases of this sort of which he had now collected nine instances. He had now examined forty cases of aneurysm of the pulmonary artery. With regard to the sides of the chest affected, he found that they were almost exactly equal; nineteen were right-sided and twenty-one left-sided. The majority existed in the lower two-thirds of the lungs, and aneurysms were not so uncommon at the base of the lung. Dr. Reginald Thompson had pointed out that in the base of the lung aneurysms were near the diaphragm, and here the more active movements of respiration hinder thrombosis, and so favour ectasia of vessels. With regard to the number of aneurysms, he had found multiple aneurysm in eleven cases. The greatest number was twenty-two; there were six in one case and three in another, and two in the remaining eleven cases. Of the forty aneurysms thirty-three occurred in men and seven in women. There were twenty-eight fatal cases of hæmoptysis in men and seven in women. With respect to the nature of the cavity, it was a chronic one; but he had found aneurysms in acute cavities having no lining membrane and with caseous soft walls, especially at the base of the lung; thus strengthening Dr. Reginald Thompson's view. The aneurysms had not been peripheral in more than half of the cases, and here his statistics differed from those of Dr. West. The size varied from that of a hemp-seed to that of a small orange. He did not think the endarteritis was due to propagation of a change from the wall of the cavity to the vessel. The primary endarteritis occurred on the exposed side of the vessel, and was probably due to purely mechanical causes. With regard to shape, there were two varieties: the sacculated and the fusiform. The former was the more common of the two; he had met with only four of the latter variety. Thrombi existed in a very great number of the specimens. A triangular slit was most common, but longitudinal ruptures were also seen. As to the identity of the pathology of fatal and non-fatal hæmoptysis, he could not agree completely with Dr. West. With Dr. Reginald Thompson, he thought there was some peculiar hæmorrhagic diathesis in some of the cases of hæmoptysis.—Dr. EWART made some remarks on the pathology of aneurysms of the pulmonary artery. He considered that the alteration of the lung tissue played a considerable part in the causation, for there was increased blood pressure in the pulmonary artery, and the right side of the heart overacted in cases of chronic phthisis, owing to the production of compensatory emphysema. This force acting from within the diseased vessels, and the tendency which the respiratory movements had to dilate the exposed portion of the arteries, were probably the most important factors in the production of aneurysm of the pulmonary artery.—Dr. THEODORE WILLIAMS referred to the literature of fatal hæmoptysis. Rokitanski had observed aneurysms of the

pulmonary artery. Dr. Fearn of Derby had written a good account of the subject. Dr. Peacock, Dr. Quain, and Dr. Cotton had collected specimens. Rasmussen had written perhaps the earliest and fullest account. He had not found a satisfactory answer to the question of the relation of fatal to non-fatal cases of hæmoptysis in Dr. West's explanation. He remarked that the discovery of bacilli closely crowded in the vessels by Ribbert might explain some of the cases of early hæmoptysis.—Dr. S. WEST, in reply, said he had not wished to discuss the views of other individuals, but simply to record fresh statistics. Ulceration and aneurysm of vessels might be shown to be closely allied in pathological nature.

MEDICAL SOCIETY OF LONDON.

Electric Illumination of the Various Cavities of the Human Body.

AN ordinary meeting of this Society was held on Monday last, Mr. Arthur E. Durham, F.R.C.S., President, in the chair. There was a numerous attendance of Fellows, who were attracted, no doubt, by the demonstrations given by Dr. Felix Semon. The paper read by Dr. Semon will appear in full in our columns.—Mr. DURHAM congratulated Dr. Semon on the success of his demonstration.—Dr. SYMES THOMPSON had found Dr. Semon's laryngoscope of much value in a case of sarcoma of the tongue, and he considered the instrument a great addition to our means of investigating the condition of hidden parts.—Mr. STOKER showed an electric lamp somewhat similar to that used by Dr. Semon.—Dr. MILLER ORD said that one great advantage of Dr. Semon's instrument was that it was exceedingly portable. It was also of much use in making demonstrations to a class.—Dr. GILBART SMITH had worked at the subject for a year and a half, but confessed that he had not been so successful as Dr. Semon. The difficulty of warming the mirror was great when the electric lamp was used.—Dr. THEODORE WILLIAMS asked where the instrument could be obtained, and what its price was.—Dr. THUDICHUM believed that no battery was equal to a Grove's battery, and he had come to this conclusion after an experience of twenty-five years. He did not agree with Dr. Semon that the laryngoscopic arrangement with the electric lamp did away with double reflection. In rhinoscopy he thought that the instrument would be of less value than the methods at present in use; it might be of use for examining parts which were not in the direct line of sight.—Dr. FELIX SEMON, in reply, said that the instrument was to be obtained from Messrs. Weiss and Son, 62, Strand, W.C. The cost of the whole apparatus would probably amount to not more than £5. The mirror used in laryngoscopy must be warmed in the ordinary way before being applied to the stem of the instrument. The accumulators were not meant to do away with the batteries or Drummond's limelight, and in no way rivalled them. He confessed that he had never been able to look into the antrum of Highmore.

HARVEIAN SOCIETY OF LONDON.

A MEETING of this Society was held on Thursday, the 5th inst., Dr. T. Morton, President, in the chair.

Mr. W. H. EVANS read notes of a case of Labour complicated by Vaginal Hernia. The tumour, when first discovered, was small, and situated in Douglas's pouch; it gradually increased in size, and fluctuation was obtained. When seen in consultation by Mr. Bryant it had so far enlarged as to allow percussion to be practised when the labia were separated. The resonant note obtained left no further doubt as to its nature. Labour occurred at full term, and much anxiety was occasioned by the protrusion of the tumour at each successive pain. Taking advantage of an interval of rest, Mr. Evans was able to reduce the hernia and rapidly to bring the labour to a satisfactory termination. The patient did well. Dr. ALDERSON mentioned the case of one of his patients, in which an eminent obstetric physician, since deceased, had, in consultation with him, diagnosed hernia in Douglas's pouch. The lady, then four months pregnant, was recommended to spend three months in bed. After delivery, which took place without further complication, the swelling was discovered to be not hernial, but, as Dr. Alderson originally believed, cystic. It was punctured, and sebaceous matter escaped.—Dr. SILCOCK suggested that the tumour in question might have been a congenital ovarian cyst.

Mr. COWELL read a paper on Purulent Ophthalmia in Infants. It had for its special aim to show that the large amount of blindness due to this disease (constituting one-third of the cases of blindness in this and other European countries) could be avoided if (1) the people could be instructed as to its dangers, and if (2) medical men universally recognised the futility of only temporising measures. The action of the Ophthalmological Society and their recommendations for checking the disease were a move in the right direction; but their appeal to the President of the Poor-law Board had not been successful owing to some practical difficulties of time and cost. It was therefore likely that the burden of the fight against this evil must fall upon the members of the profession. This great object could best be attained by unremittingly and by every means endeavouring to diffuse a knowledge of the disease and of its dangers through the dispensaries, the clubs, the lying-in institutions, and the visitors of the sick poor. Prophylaxis was the next duty. Why should not antiseptic precautions form part of the routine of every lying-in case? In respect of treatment, the first essential was that no time should be lost. The indications were (1) to remove the conjunctival discharge as rapidly as it formed; (2) to relieve tension; and (3) to watch and treat the complications. In addition to the usual rules of treatment, Mr. Cowell recommended that the affected eyes should be cleansed every quarter of an hour with weak antiseptic lotion, and the conjunctivæ painted with from four to six grains of solution of nitrate of silver daily in severe cases, twice or thrice a week in mild cases; the free solution being washed away with antiseptic solution. Where there was much discharge alum or boracic acid might be added to the lotion. The cul-de-sac under the upper eyelid required careful washing out. The ablutions might be less frequent during sleep, and gradually diminished as the discharge lessened. When severe chemosis occurred early scarification was necessary.—Mr. JULER inquired whether severe cases could be diagnosed early from milder ones. He quoted some investigations of Dr. Widmark (*Revue Générale d'Ophthalmologie*, Sept. 1884), in which twenty-two cases of purulent conjunctivitis had been examined (four adults and eighteen infants). Bacteria, described as gonococci, were found in the majority of these cases in the fluid, on the pus cells, and on the epithelial cells. In the adults he discovered gonococci in the urethral secretion, and in the infantile cases in the urethral discharge of the mother. The gonococcus was absent in six of the infantile cases which ran a mild course. Mr. Juler exhibited a specimen of bacteria which he considered identical with gonococci. The antiseptic solution used for the ablutions should be weak (¼ per cent. carbolic or boracic acid). The conjunctivæ, if severely swollen, should be freely scarified, and if eversion of the upper lid were impossible the outer canthus should be divided.—Mr. H. POWER, speaking from the experience of the ophthalmic department of two large institutions, would have mentioned 10 to 15 per cent. only as the percentage of blindness due to ophthalmia neonatorum. The discovery of the gonococcus was due to German observers, who had long forestalled the observations which had been mentioned. Independently of prophylactic measures, which should not be neglected, the eyes of infants were generally protected by the agglutination of the palpebræ. When due to gonorrhœa, cases were likely to do badly unless they received skilled treatment early. On a wide average, cases, if seen in the first week, would recover; if in the second week, they would run a dangerous course; if in the third week, they were hopeless. Ablutions practised every hour, or every two hours, were sufficient as a rule; but it was important to remove the stringy precipitate which generally adhered to the margin of the lid after the application. As a disinfectant, half a grain of nitrate of silver to the ounce was an appropriate strength; for the purposes of stimulation two grains to the ounce should be used. Scarification was strongly deprecated, and division of the canthus was seldom requisite and most undesirable.—Dr. ALDERSON mentioned a case in which he had with great success, but not without pain to the patient, insufflated a dose of calomel into the conjunctival sac.—Dr. BLENKINSOP, in his former experience as obstetric assistant to St. George's Hospital, had found the use of a lotion of sulphate of zinc (two grains to the ounce) generally successful. One or two of his cases only were, however,

gonorrhœal.—Dr. M. HANDFIELD JONES considered that the severity of the cases entirely depended upon the nature of the vaginal discharge. This was well illustrated by the irritation of the tissues of the vulva by gonorrhœal and uterine inflammatory secretions as compared with the absence of irritation in the ordinary cases of leucorrhœa, even of long duration.—Dr. F. A. HILL was puzzled to find specialists at variance on important points of treatment. In his own hands treatment by frequent ablutions had been very successful. Dr. SILCOCK was convinced of the importance of systematic ablutions; sleep should be interrupted for that purpose. Pure iodoform and pure boracic acid, among other remedies, had been tried at Moorfields, but the old-fashioned treatment by nitrate of silver had been finally resumed. Scarification was necessary in some cases, and should be employed.—Dr. C. WELLS had recently treated a case where gonorrhœa was present in the father. Purulent ophthalmia occurred two days after birth, and was treated successfully with sulphate of zinc lotion; one eye only was affected. This good result was due to the use of an antiseptic application of spermaceti and vaseline with thymol. This compound, solid at ordinary temperatures, but easily soluble by warmth or in water, would be found a useful prophylactic for surgeon and patient.—Dr. T. MORTON referred to the comparative infrequency of the affection in his own practice, which formerly had been extensive among the poor. His percentage was much below that usually laid down in text-books.—Mr. COWELL, in his reply, strongly insisted upon the curability of all cases if seen sufficiently early and if treated by frequent ablutions and by stimulant applications. The first week appeared to him to be the critical period. Scarification relieved threatening ulceration more quickly than any other method, but division of the canthus might be termed a barbarity except in a few isolated cases.

At the meeting on Thursday, Feb. 19th, Dr. T. Morton, President, in the chair,

Mr. J. H. MORGAN read a paper on the Operative Procedures in Cleft Palate, and their effects upon the Voice. After referring to the gaps still remaining to be filled in our knowledge of the etiology of the deformity, the author inquired whether cases ever occurred in which the surgeon need despair of producing some benefit by operation. Assuming that only partial closure would be obtained, the size and weight of the obturator required would be materially reduced, and its adaptation rendered easier. The wearing of an apparatus previous to operation was denounced on account of expense and of the damage caused to the teeth, as well as of its ill-effect upon the state of the cleft. Partial failure to close the whole opening at a first attempt did not stand in the way of complete success on a second occasion. The period between two years and a half and three years was recommended as the most suitable age for operation. The method of dividing with curved scissors the attachment of the soft to the hard palate, and of making long incisions parallel to the edges of the cleft, was advocated as the best means of reducing tension, and as less likely to interfere subsequently with the action of the muscles of the soft palate and with their function of closing the opening between the nares and the pharynx. An analysis of twenty-five cases was given; fourteen were completely successful and ten partially so; one failed on the first attempt, but was dealt with successfully later. The result upon the voice in those cases where attention had been given to proper training was stated to have been most satisfactory, and the necessity of careful and systematic teaching after the operation was strongly urged.—Mr. CARMALT JONES referred to cases where the results, ten years after the operation, were not satisfactory, the soft palate being excessively tense. Such cases supplied an argument in favour of deferring interference until the age of puberty.—Mr. T. PICKERING PICK had performed the operation in a considerable number of cases. Before the introduction of Smith's gag early operation had been impracticable; it had now become the rule, with the result that the habit of nasal intonation, so difficult to eradicate when once acquired, was generally avoided. Mr. Pick's first patient, operated on at the age of three years, had since been educated as a vocalist. In some cases, however, the dentist's obturator achieved better results than the knife, although the necessity for frequent renewal and the damage done to the teeth were strong arguments in favour of operating. Distinct articulation could be taught by causing the children to strike a board with the finger at each syllable. In every case the whole palate should be operated upon, partial operations having led to ultimate failure. The first condition for success was complete absence of tension on the sutures; free incisions were necessary, and never did harm.

Dr. C. T. WILLIAMS related cases of Emphysema treated by the Compressed Air Bath. The author, after fully describing the machinery and the working of the compressed air bath in use at the Brompton Hospital, proceeded to give illustrative cases of the specific effects of this agent. 1. A mechanical influence was exerted by the increased pressure on those surfaces of the body which were specially exposed, such as the skin, the aerial mucous membrane, and conjunctiva; dilatation of the bronchi and intropulsion of blood from the superficial veins and capillaries into those of the deeper organs which were protected by bony cavities—skull, spine, thorax, and pelvis—were among the mechanical results described. 2. Physiological and chemical effects were due to the increased amount of oxygen inhaled, which showed itself in quickened tissue change and larger excretion of carbonic acid and urea. With regard to emphysema, Dr. Williams' conclusions were that by the use of the compressed air bath (1) cough and expectoration were allayed and bronchial spasm reduced; (2) respirations were diminished in number and increased in depth; (3) pulmonary distension was relieved, and the active respiratory area increased; (4) a fall in the pulse-rate and a rise in arterial tension were effected; (5) the secretion from the kidney and liver was assisted, and thus derivation from the aerial mucous membrane brought about; (6) lastly, body weight was increased. Diagrams, pulse tracings, &c. illustrated the remarks contained in the paper.—Dr. SANSOM expressed his appreciation of the new departure in the treatment of emphysema. He had formerly tried Waldenburg's apparatus with disappointing results. He was nevertheless a believer in mechanical treatment, which he had used in three forms: (1) forced expiration, (2) bandaging the chest, (3) shampooing. Forced expiration could be practised very effectually without the additional aid of the air-pump, which Dr. Berkart had recommended, if patients were directed to blow a stream of air through a tumbler one-third full of water till they could no longer produce a bubble. This exercise might with advantage be continued for ten minutes and repeated during the day.—Mr. FRANKISH, Mr. CRIPPS LAWRENCE, Mr. WHITCOMB, and Dr. EWART also took part in the discussion.—In his reply, Dr. WILLIAMS pointed out that whereas fifty air-baths were in use on the Continent, only one existed in London, and one in the provinces (at Ben Rhydding). It was hoped that arrangements for rarefaction of air would be added to the Brompton apparatus. The immediate effects of a bath passing off within twenty-four hours, a course of at least thirty, and, preferably, of sixty baths, was recommended. With regard to the question of danger in dilatation of the right cavities of the heart, Dr. Williams had observed no ill effects, but a decided amelioration, unfortunately temporary, in the only severe case which he had treated. The main source of danger in all cases was carelessness in effecting a very gradual transition from high pressures to the normal. Workmen could spend hours comfortably under a pressure of five or six atmospheres, but when the pressure had been suddenly reduced in the pneumatic tubes, death had occurred from cerebral and spinal hæmorrhage. The subject of atmospheric pressure in mines was also commented upon.

EPIDEMIOLOGICAL SOCIETY OF LONDON.

AT a meeting of this Society, held at 11, Chandos-street, Cavendish-square, on Feb. 11th, Dr. Norman Chevers, C.I.E., President, in the chair,

Dr. K. M'LEOD read a paper on "The Prevalence of Epidemic Roseola in Calcutta," of which the following is an abstract. He stated that an epidemic of measles had visited Calcutta during the year 1880 and the early part of 1881. This was succeeded by an outbreak of cases of an eruptive fever which appeared sporadically throughout the town among all classes of the population, affecting principally children and young adults. It lasted throughout the hot weather and rains of 1881, and cases continued to occur during the cold weather of 1881-82. The phenomena and course of these cases differed in many respects from those of the earlier epidemic. The symptoms of the disease were a distinct pre-

eruptive stage, lasting generally from twenty-four to thirty-six hours, and characterised by the sudden onset of fever. Muscular pains were sometimes present, vomiting and diarrhœa were rare, and sneezing and watery eyes not common nor severe. The eruption lasted two or three days, being bright-red or crimson in colour, circular in shape, and appearing in spots and patches, sometimes diffuse or confluent; it was not succeeded by desquamation. The fever was severe, onset sudden, decline gradual as the eruption faded. The total duration of illness was about a week. The most commonly observed complications were bronchial catarrh and tonsillitis, the tonsils being sometimes covered with an aphthous pellicle and slight ulceration taking place. The lymphatic glands of the neck were enlarged in many cases; sequelæ were absent and the mortality trifling. The disease was not very infectious, but cases occurred in succession in the same family. It was also noticed that a previous attack of measles was not protective, and an instance was recorded in which an attack of measles occurred shortly after recovery from the disease. Dr. M'Leod thought that the disease resembled very closely rubeola or rötheln; there could be no question of identity with scarlatina, because in addition to well-marked clinical differences, it was a well-known fact that though single cases were often imported in troopships, scarlatina as an epidemic disease did not exist in India. It was a question whether these were not cases of some other kind of fever, such as mild malarious remittent, complicated by a roseolar rash; but this was shown to be impossible by the similarity of the symptoms as observed by different practitioners and the number and grouping of the cases. The evidence thus pointed to the view that this was an epidemic of rötheln, and, if this were so, it became an interesting question whether similar outbreaks occurred from time to time in other tropical countries and places.—In the discussion which followed, the President, Sir W. R. E. Smart, Surgeons-General de Renzy and W. J. Moore, Drs. Duka, Cayley, Squire, and Thorne, and Messrs. Shirley Murphy and Charles Paget took part.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

A MEETING of the above Society was held on Jan. 15th, Mr. W. A. Garrard, President, in the chair.

Mr. ARTHUR JACKSON related a case of Strangulated Hernia on which he had operated on Dec. 25th, 1884. There was nothing particular about the operation; the difficulty was in the diagnosis. A scrotum full of something; a special and recent tumour outside the internal ring; spasmodic sickness; no abdominal distension; a good countenance; a quiet pulse; and very slight hiccough. A recent tumour appeared on Tuesday, Dec. 23rd, late in the evening; the scrotal swelling was chronic. With diffidence herniotomy was performed, and on cutting down upon the recent tumour a port-wine coloured piece of bowel was found very tightly constricted, which was reduced with difficulty.

Dr. GWYNNE introduced a lad, aged ten years, subject to the condition known as Hæmophilia. This boy he had known almost from his birth, and had frequently treated him for hæmorrhages from his fingers, tongue, nose, scalp, and various other parts of the body, caused by injuries generally of a very slight nature. The right knee was slightly contracted, and the lower extremity of the femur was much larger than its fellow. When about a year old he had knocked it when in bed, and in the morning it was found much swollen; since that time the condyles had become enlarged, and that knee has become weaker and the hamstring muscles slightly contracted. He was an active boy on his legs, except when suffering from the effects of slight knocks. Dr. Gwynne had sometimes counted more than half a dozen ecchymoses on different parts of his body. His growth was stunted, and he was only the same height as his brother, who was two years younger. There was no family history. His complexion was dark.

Mr. PYE-SMITH showed a wedge of bone which he had recently removed from the lower end of a man's femur for the cure of Genu Valgum. The patient was a cab-driver, aged twenty-eight. He had been admitted into the public hospital on account of a partial dislocation outwards and on to the inner edge of the left patella. This was reduced under ether by flexing the knee, and the osteotomy had subsequently been performed to remedy the knock-knee. The degree of deformity was very great, the legs forming an angle somewhat greater than a right angle when the knees were placed together in bed. A wedge of bone was removed by means of a small saw from just above the condyles of the left femur, the apex of the wedge having an angle of about 40°. Listerian antiseptic precautions and dressings were employed. The case is progressing favourably, and it is intended soon to operate on the other limb, which is equally affected.

Mr. C. ATKIN read a paper on Natural Drainage in Otorrhœa, in which, after noting that in fatal cases the Eustachian tube was usually found more or less blocked, he went on to say that though cleansing of the tympanic cavity, "per tuban," was recommended in cases of inspissated secretions, not sufficient stress was laid on the necessity of keeping the tube open for drainage purposes in all cases. The usual routine treatment of allowing powders and drops to be applied to the ear, followed by a plug of cotton-wool "to keep the cold out," was condemned, unless a previous examination had shown that the Eustachian tube was in a patent condition. Notes of a fatal case were read where the pus had not burrowed back into the mastoid cells, but had ulcerated through into the roof of the pharynx, causing an intermittent fetid discharge through the nose. The case, a man aged twenty-one, died the second day after admission into the infirmary from abscess of the cerebellum.

At the meeting on Jan. 29th, Dr. BANHAM presented two cases of Hydatid Disease, one of the liver and the other of the spleen; the first after being twice aspirated, the brief notes of which are: A girl, aged fourteen, was first aspirated eleven months ago, and two quarts of clear hydatid fluid were drawn off. After the operation acute febrile symptoms with incessant vomiting set in, and it was found that the cyst had completely refilled. It was again aspirated six months after the first operation, and apparently nothing but pus was drawn off, about one quart in quantity. Since then the patient has been restored to perfect health. Dr. Banham's second case was a girl, ten years of age, with a large well-defined tumour in the left hypochondriac and epigastric regions, freely movable, firm, and elastic to the touch, which was diagnosed as a case of hydatid of the spleen.

Dr. BANHAM introduced a woman, thirty-eight years of age, who had long suffered from Cephalalgia. Three years ago she was attacked with left hemiplegia, and four months ago with a loss of the sight, so that she was only able to see objects on the right hand side. In neither of these attacks was there unconsciousness, and they were two days in attaining their full development. On examination there was marked paresis of the left side, and on testing her right with the perimeter there was found to be right hemianopia, the vision in both cases passing just beyond fixation point. The left pupil was larger than the right. The pupillary reflex was absent, and there were no morbid ophthalmoscopical appearances. Dr. Banham considered that the left hemiplegia was due to thrombosis of the right middle cerebral artery, and that the hemianopia was due to a similar cause, affecting a branch of the post-cerebral artery supplying the posterior part of the optic thalamus and the corpora geniculata and corpora quadrigemina, or to a point of softening in the optic thalamus. The condition of the pupils seemed to exclude a purely cortical or subcortical lesion of the occipital lobes, while the healthy condition of the retina favoured the view that it was not a purely tract lesion.

Mr. S. SNELL related particulars of a case of Blindness, in a man aged forty, occurring rapidly, within three days, in the right eye, and a short time later, in an almost equally rapid manner, in the left. Light perception was abolished in each eye, with negative ophthalmoscopic signs. Mr. Snell gave his reasons for supposing a lesion of the region of the chiasma, and promised further particulars of the case later on.

Mr. SNELL also exhibited a patient with Paralysis of External Recti. The left sixth nerve had been affected for three or four weeks, but during the last few days the right had become also paralysed, and it was feared further evidence of central disease was developing, when the case would be again brought to the notice of the Society.

Dr. GWYNNE read a paper on the Treatment of Empyema, and gave notes of four cases in children that came under his care during the latter half of last year. He advocated the choice of the seventh right and eighth left interspace for paracentesis behind the line of the axilla, as these points

were well above the highest level of the diaphragm in forced expiration. He laid great stress upon keeping the pus aseptic, as few patients bore well frequent washings of the pleural cavity. He preferred using a trocar and cannula to incision with a knife, as being more cleanly and allowing of more control over the too rapid escape of the pus, and allowing of the easy introduction of the drainage-tube through the cannula; a double opening was rarely necessary or desirable. He believed that the drainage-tube was often kept in far longer than was necessary, keeping up by its presence much irritation and discharge. In children he thought there was nothing gained by too early opening, as at first the empyema was often multilocular and some delay broke down adhesions and made it unilocular, a matter of no small importance when drainage was established. In children empyema was not, he thought, often preceded by serous effusions.

MIDLAND MEDICAL SOCIETY.

AN ordinary meeting of this Society was held on Feb. 4th, Mr. T. H. Bartlett, President, in the chair.

Dr. MALINS read a paper on a case of Inversion of the Uterus. The patient, aged nineteen years, was confined of her first child on June 1st, 1883, after an easy labour attended by a midwife. She had tedious convalescence owing to continued hæmorrhage, and became anæmic and weak. She was admitted into the General Hospital on Oct. 24th, several attempts at reduction having previously been made. The uterus was found to be dense, completely inverted and involuted, the vagina lax and capacious. Under ether an attempt was made by taxis, steadily applied for an hour, without any impression being made in reducing it; a further trial was also made about a week later. On Nov. 20th the abdomen was opened in the middle line, a strong silk thread passed through the fundus into the vagina, and a button fastened on the distal side. Considerable traction was made on this ligature with counter-pressure by one hand without any yielding; this was persisted in for nearly an hour. The wound was then closed. There was much shock, the temperature going up to 104°, and the pulse becoming quick for eight or nine days—120 to 140. On Dec. 21st an elastic ligature was put round the base of the uterus in the vagina. On Jan. 1st the uterus was detached; the stump healed well, there were no bad symptoms, and the patient was discharged cured on Jan. 14th.

Mr. J. W. TAYLOR showed a case of Congenital Syphilis in an adult, with gummata around the left knee-joint. These, which had been noticed from childhood, and at one time seriously interfered with locomotion, had greatly diminished in size under prolonged treatment; the tumours remaining had probably undergone changes preventing further absorption. Some syphilitic symptoms had been observed in children of the third generation.

Dr. SUCKLING showed a case of Muscular Atrophy due to lead. The patient was a man aged forty-one, who had been a gasfitter. The interossei and extensor muscles in both upper extremities were wasted, and the "main en griffe" present in both hands. There were no electrical alterations. Dr. Suckling considered that the case was one of simple muscular atrophy, and not progressive, for the following reasons: (1) The weakness was far in excess of the atrophy; (2) there had been marked improvement under the administration of iodide of potassium; (3) the paresis came on somewhat suddenly.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

THE ordinary monthly meeting of this Society was held on Feb. 6th, Dr. Bell, President, in the chair.

Dr. JAMES ALLAN showed a section from a Concretion in the Kidney exhibited at the last meeting, the structure being true bone. He also showed sections of Osseous Plates from the Membranes of the Brain.

Dr. EDDISON showed a specimen of Microsporon Furfur from a patient in whom the growth took the unusual form of rings.

Dr. GRIFFITH showed a series of specimens illustrative of various forms of Malignant Infiltration of the Liver, including Carcinoma and Lymphosarcoma. He also showed a series of specimens of Intestinal Ulceration.

Dr. JACOB showed a case of Tumour of the Vocal Cord by means of a new electric light, in which the lamp was attached to the laryngeal mirror.

Dr. CLIFFORD ALLBUTT spoke briefly on two cases of Lead-poisoning. In the first case (a man of sixty) an indefinite cachexia alone existed, with much general debility, no definite colic or constipation, and no relative weakness of extensors, and gums devoid of teeth. A sudden attack of lead colic in the son betrayed the cause, and the source of the poison was found in the water-supply. In the second case, a man of fifty had been long treated for hypochondriasis. An estimate of urea proved renal excretion to be very deficient, and on renewed attention being given to the urine fleeting traces of albumen were discovered. A faint lead line was found on the gums, and traced to his occupation. Dr. Allbutt inquired whether in plumbism there might be a stage of defective nitrogenous excretion preceding the signs of organic renal disease.

Mr. HEWETSON showed a girl aged eighteen, in whom an attack of Acute Glaucoma occurred in one eye in October last. When first seen the attack had lasted five days. All the symptoms were those of an ordinary attack of acute glaucoma, accompanied by almost entire loss of vision. After the instillation of eserine, an iridectomy resulted in a rapid diminution of intraocular pressure, and consequent improvement of vision. At the end of a week after the operation she was able to read Jaeger 1 fairly well. Mr. Hewetson remarked on the rarity of glaucoma in one so young, and on the necessity of early iridectomy.

Mr. PRIDGIN TEALE related a case of Abscess discharging through the Lung and originating between the Diaphragm and Liver, which was cured by incision and drainage through the pleural cavity. Within six months of the operation the patient was in vigorous health.—Dr. C. J. B. JOHNSON had seen the case, and had followed out the after-treatment. The principal difficulty arose in the occurrence of severe dyspnœa after the operation, through admission of air to the pleura, the other lung being at the time partially solid. This was obviated by covering the wound with absorbent wool secured by adhesive plaster. Recovery was then uninterrupted.—Mr. MAYO ROBSON remarked on the difference between a healthy pliable pleura and one thickened by disease, as in empyema.—Dr. CLIFFORD ALLBUTT drew attention to the "anginiform" pains experienced by the patient. He reminded the meeting that a condition of intense orthopnœa and anginiform agony may be caused by diaphragmatic pleurisy, which can be inferred from the entire absence of any pneumocardiac signs.

Reviews and Notices of Books.

The Year-book of Pharmacy for 1884. Edited by LOUIS SIEBOLD, F.I.C., F.C.S. London: J. and A. Churchill. 1885.—It is always a pleasure to us to receive this useful and ably-edited Year-book of Pharmacy. As a work of reference to all that appertains to materia medica, chemistry, and even therapeutics, it is probably unsurpassed. The present volume is of especial interest, containing as it does the able address delivered by the president, Mr. John Williams, at the meeting of the British Pharmaceutical Conference at Hastings in August last. The majority of the papers read on that occasion were far above the average. It is worthy of note, as showing the activity which prevails amongst chemists, that abstracts are given of no less than nine papers on ptomaines and analogous compounds. Another subject which seems to have attracted a good deal of attention is the change undergone by starch in the process of conversion into sugar under the action of diastase. In connexion with this matter we cannot refrain from calling attention to a statement in a paper by Mr. Jugk, who is made to say that "a good extract of malt should convert its own weight of starch within ten minutes at 100° F." We are not told what starch is referred to, but if potato starch is meant, we should consider it a very poor extract of malt, and should condemn it without

the slightest hesitation. We are somewhat surprised to find no reference in the index either to the oleates or to cocaine. The abstracts, we see, are made up only to June 30th. Why this should be we are at a loss to understand. There would be no difficulty in bringing the work up to date. It is so good that we feel we have a right to ask for more of it.

Hygiene, its Principles as applied to Public Health. By E. F. WILLOUGHBY, M.B. Pp. 305. London: Collins and Co. 1884.—This volume, which forms one of Collins's advanced science series, has been written chiefly for the use of students reading for the examinations in hygiene held by the Science and Art Department, and for the certificates in sanitary science given by the University of Cambridge. It treats of food and water; ventilation and heating; sewerage, drainage, and sanitary appliances; meteorology and climate; personal hygiene; injuries, accidents, and preventable diseases; with a very brief notice, in the appendix, of dangerous, unhealthy, and offensive trades; of sewage disposal, and of the principles and facts and some of the fallacies of statistics. It appears to have been carefully drawn up, and to give a good, clear, and intelligible account of the general principles applicable to questions of public health. We are surprised, however, to find a recommendation given to administer an emetic to a man who is "dead drunk" without the slightest caution as to the danger arising from an individual in this deplorable condition being laid on his back. The risk of asphyxia under such circumstances should have been pointed out. With a view to make the work available as a text-book alike to the students for the elementary and the advanced examinations, the parts which are necessary for the former are printed in large type, while the additional and more detailed information required for the latter is given in a smaller type. The work appears well calculated to answer the purpose intended, and to furnish for the non-professional reader good general information on the subject of public health and the measures necessary to maintain and improve it.

Myths in Medicine, and Old-time Doctors. By ALFRED C. GARRATT, M.D. New York and London: G. P. Putnam's Sons. 1884.—The scope and intention of this book are thus set forth by the author in the introduction: "These chapters record medical history and the successive medical schools and sects; also the medical improvements along the ages, excepting the present, these being the gleanings of special studies in medical history. The work is addressed to the profession, especially the younger portion of it, and to an intelligent public—in plain language, for all readers. . . . Here are traced the rise and progress of the great medical profession, the old and new healing art; also the new phase of a very old fashioned medical 'school,' each inspected anew by routes not usually taken, so that important facts that should be familiar to everyone may be readily understood by any and all." It may be as well to explain that "the new phase of a very old fashioned 'school'" is homœopathy, Dr. Garratt pointing out that the so-called law of *similia similibus curantur* was on record two thousand years before the time of Hahnemann. The last chapter of the volume is therefore devoted to a searching, and so far as regards *potencies* a mathematical, analysis of that still existing myth in medicine. The preceding chapter—dealing with the question, What was alchemy in the seventeenth century?—concludes with the following words:—"The third phase of alchemy crops out in our own time most prominently in the so-called system of homœopathy." For the author's justification of this assertion we must refer the reader to the concluding pages of the book. The body of the work contains many interesting excerpts from the works of ancient writers, medical and otherwise. It is interesting to note the antiquity of specialism (dating back to B.C. 1400 or 1500, when it was a legal and precautionary method for the ensuring of thoroughness!) and of splenectomy. An old-time theory of the pathology of aphasia is also curious:—"That the traces of the nerves in the tongue being defaced, or closed up, the Spirits that do duty to that organ, though directed to one part, finding those avenues shut up, are compelled to go into those that are not obstructed." To those who have not time and opportunity to gather for themselves gleanings from the past we can recommend this interesting little book.

The Harveian Oration. By J. RUSSELL REYNOLDS, M.D., F.R.S. London: J. and A. Churchill. 1884.—The appearance in a separate form of the Harveian oration delivered by Dr. Russell Reynolds in October last calls for a brief notice at our hands. We do not envy anyone the task of having to compose an oration dealing with a subject which, however interesting, cannot legitimately be regarded as inexhaustible. Yet it must be confessed that the many Harveian orators have not failed to make something out of their study of Harvey's life and work. The conditions under which the Harveian oration was founded preclude, we believe, the possibility of diverging in any degree from the subject of Harvey himself. It follows that each successive orator finds the ground more and more cut from under his feet. Be this as it may, it cannot be gainsaid that the latest attempt has proved anything but unsuccessful. Dr. Reynolds's oration is admirable; it contains much that is poetically beautiful and instructive. The truth is that Harvey's life and work present so many aspects that a sort of permutation and combination is possible whereby new arrangements of the matter can be made by those possessing the necessary ability. Dr. Reynolds sought to show, with considerable reasonableness, in the third part of his discourse, that Harvey was religious, yet free from the restraints of theology, an observer, a questioner, and interpreter of Nature. He made legitimate, and only legitimate, use of working hypotheses. He was at once bold, meek, and cautious, and fully realised the value to be attached to the conclusions to which others had come who had looked at facts for themselves. In much of his writing Harvey was both humorous and eloquent. His great achievements were the result of his method—namely, that of observation and experiment.

Medical Education and the Regulation of the Practice of Medicine in the United States and Canada. Chicago: W. T. Keener. London: Trübner and Co. 1884.—This work, prepared by the Illinois State Board of Health and published by permission of the board, gives a brief but sufficient account of the various medical institutions in the United States and Canada, extinct and existing, including examining and licensing bodies, the organisation and requirements for admission and graduation of the medical colleges, auxiliary and post-graduate schools, &c. Drawn up originally to form a section of the fifth annual report of the Illinois State Board of Health, the work is valuable to all, inasmuch as by reference to it the standing of any one of the many medical colleges existing in the United States and Canada may be readily determined.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—The officers and other members of Council of this Society nominated for the year 1885-86 are as follows:—President: George Johnson, M.D., F.R.S. Vice-Presidents: W. O. Priestley, M.D.; Hermann Weber: T. Bryant; M. Berkeley Hill. Treasurers: C. B. Radcliffe, M.D.; T. Holmes. Secretaries: R. D. Powell, M.D.; Howard Marsh. Librarians: Wilson Fox, M.D., F.R.S.; J. W. Hulke, F.R.S. Council: H. Charlton Bastian, M.D., F.R.S.; W. H. Broadbent, M.D.; T. Buzzard, M.D.; W. S. Church, M.D.; C. T. Williams, M.D.; Warrington Haward; Sir Wm. Mac Cormac; T. P. Pick; W. Sedgwick; W. Rivington.

THE LANCET.

LONDON: SATURDAY, FEBRUARY 28, 1885.

THE movement for the promotion of a Teaching University in London has met with the strongest support in a quarter in which perhaps it might least have been expected. The graduates of the University of London have not given the proposal a chill reception or bowed it out of doors, but have accorded it a hearty welcome. Their decision on Tuesday last is destined to have an influence over the future of the University greater than that of any event which has occurred since the necessity of collegiate instruction for degrees in all faculties, except in that of Medicine, was done away with, some twenty-five years ago. Since that time no such question of primary importance as that connected with the promotion of a Teaching University has been brought before its members. In no grudging manner, but by a very large majority, the graduates have determined "that in the opinion of Convocation the objects of the Association for promoting a Teaching University for London would, if carried into effect by this University, add to its usefulness and importance." The objects of the Teaching University, as stated by Lord Justice FRY in moving the resolution, must have so important and extensive a bearing on medical education in this country that we recapitulate them, although they were given in full in our editorial columns on the 14th inst.:—

"1. The organisation of University teaching in and for London, in the form of a Teaching University, with Faculties of Arts, Science, Medicine, and Laws. 2. The association of University examination with University teaching, and direction of both by the same authorities. 3. The conferring of a substantive voice in the government of the University upon those engaged in the work of University teaching and examination. 4. Existing institutions in London of University rank not to be abolished or ignored, but to be taken as the bases or component parts of the University, and either partially or completely incorporated, with the minimum of internal change. 5. An alliance to be established between the University and the professional corporations, the Council of Legal Education as representing the Inns of Court, and the Royal Colleges of Physicians and of Surgeons in London."

It is at once apparent that the adoption of these objects must determine a new departure in the history of the University. The proceedings of the executive authority have satisfied neither the teachers nor its wisest and most far-seeing graduates. The University was founded on non-sectarian principles at a period when the older Universities refused to give their degrees to students who could not accept the doctrines of the Established Church; but when that barrier was removed, the special *raison d'être* of the University of London no longer existed. Instead of strengthening the teaching in England, the executive had opened the portals of the University to all comers, and, by refusing to acknowledge the advantages of a definite collegiate training, did a great deal to destroy the influence and prestige of the higher colleges. It had a first warning of the dangers of this step in the conversion of Owens College into the Victoria University, and now it has received another hint, the significance of which it will not be wise to ignore. The foresight of its own graduates must necessarily compel the Senate to depart from their old *rôle* of a mere examining board for the State, and take on those higher duties which, from its position, the University of London should never have neglected. An illiberal disregard of every educational movement and a selfish adherence to an old educational idea have brought a just Nemesis on the doctrinaires who rule the Senate. The single object of keeping the examination standard as high as possible, without the slightest inquiry as to how the information is obtained (as if there were no difference between such information and true knowledge), is disclaimed by the very graduates who have obtained its degrees. "The conferring of a substantive voice in the government of the University upon those engaged in the work of University teaching and examination" will be a revolution in its management, and must altogether change the character and constitution of the present executive. That such a change is not altogether acceptable to many members of the Senate was clearly shown by the speeches of Mr. OSLER, Mr. SHAEN, and Mr. HUTTON, who are members of the Senate as well as graduates in Convocation, although it might have been more gracious on their part if they had waited for its presentation to the former body. Mr. OSLER's speech in moving the amendment—"That the House is not in a position to affirm the expediency of the adoption by the University of the diversified and indefinite objects of the Association for promoting the establishment of a Teaching University for London"—was such a deliberate attempt at ignoring the demands for a Teaching University, and of pretending not to understand the objects of its promoters, as to justify Lord Justice FRY's well-timed remark, "That there were two ways of reading a document—one, with a view to understand it, and the other, with a decided intention not to do so; and he need not say which the inner circle of Senators had obviously been pursuing." Moreover, the Senate will scarcely have power, even if it has the inclination, to ignore the vote of Convocation, for a second resolution was adopted in the following terms:—

"That Convocation now reappoints the Special Committee appointed on January 6th, 1885, to promote the carrying into effect by this University of the objects of the said Association, with power to confer with the Senate or any committee thereof, and with the said Association, and with such other bodies and persons as they may think fit, and with power to accept resignations, fill up vacancies, and add to their number, and also to appoint subcommittees; and that the said committee be directed to report to Convocation from time to time as occasion may require."

A standing Committee is therefore appointed, with which the Senate must work, or else come into collision, and if the latter course be chosen, the result can scarcely admit of doubt.

What will be the effect of this new movement on medical education and medical degrees in London? Consolidation of preliminary and scientific teaching seems to us to be inevitable, and would be of unspeakable advantage. Degrees will be rendered accessible to every industrious and fairly intelligent student, and the old restrictive regulations will

be done away with. An institution exercising some supervision over medical studies, and fostering the best aspirations of medical science, will be able to do much towards promoting higher knowledge and original investigation. Instead of educating a few men highly, the general standard must be considered, and the sacrifice of the many to the few be no longer a cardinal principle in the University which practically rules medical education in a city which presents greater opportunities for clinical teaching than any other in the world. We earnestly hope that, when definite proposals are advanced by the Association for promoting the Teaching University, these considerations will find a prominent place in their programme, and that the Senate of the existing University will not be permitted to make any compromise which will interfere with the due carrying out of the measures by which such ends may be obtained. A degree which may be accessible to every worthy student, and a constant stimulus to the enthusiasm which ennobles every true teacher and student, will do more to improve medical science in general than a severely rigid examination-test, which only disheartens the plodding and disgusts even the ambitious student.

THERE is very little probability of domestic legislation of any sort during the present session of Parliament. The "burning questions" of what used to be called Imperial policy will engross the largest share of attention in both Houses; and of the scraps of time which can be spared for minor matters at home, few can be expected to fall to the lot of the medical reformer. On the uncertainty of medical education engaging attention during the present session we expressed our views last week.

The Lunacy Laws are to be tinkered, but no one need be much moved on that score. Only the proprietors of private asylums have cause to rejoice in the position of affairs. They, indeed, may find consolation in the prospect of legislation at this conjuncture, because it goes without saying that the Government will not attempt to deal with the private-asylums system in any considerable sense, and if only something can be done without unsettling the *status quo*, all danger of disturbance will be escaped for many a long year, and asylum property will recover its value in the market with proportional celerity. At the present time the Lord Chancellor, who really knows nothing whatever about the subject, and is entirely in the hands of official wire-pullers—who have drawn his Bill for him, and will tell him what to say and how to say it,—has only one leading idea on the question, and that is that existing statutes would be the better for a little codification, and that in a few minor and practically quite unimportant points there may be room for amendment. In brief, he proposes to patch and paint the structure, and to call it by a new name—nothing more; whereas it requires to be pulled down and reconstructed on a new principle. Neither the public, sane and insane, nor the medical profession, nor the asylum keepers, need give the prospect of "lunacy law reform," so far as the near future is concerned, a single serious thought. It would be idle to do so. The lawyers may have a certain amount of interest in the promised Bill; but for us there is neither hope nor interest in it, and we can afford to wait for its appearance before we discuss it.

Far more interesting and hopeful than the prospect of new law-making in connexion with insanity is the enterprise just beginning to be shown by certain of the judges in respect of the administration of the law as it stands. Mr. Baron HUDDLESTON has already done much, and other judges are following suit, in the way of providing that, even without "reform," both the sane and the insane might be much better protected than they are, or have hitherto been. Not the least significant of logical inferences deducible from recent deliverances on the part of the judges is that no small proportion of the inmates of asylums at this present time are illegally detained, and that—the asseverations of the Commissioners in Lunacy notwithstanding—the great majority of the documents which have satisfied their petty notions of "regularity" are bad in law, and only pass as legal warrants for the detention of the poor folk named in them because they have not been judicially examined. The gross absurdity of making a mixed Commission, of no legal authority whatsoever, a court, without appeal, for the private adjudication of issues which ought to be settled in the broad light of day, stands confessed. Nothing short of a complete and sweeping measure can suffice to wipe away the reproach of our lunacy system; but it is gratifying to find that some of the more heinous abuses of that system are likely to be prevented for the future by the tardy interposition of the administrators of the law, who would seem to have just awakened to the knowledge of the fact that such miserably bad and unworkable laws exist. It is something to know that, rotten as the whole system of "certifying" and confining certificate-made lunatics is, and must for the present continue to be, it will need to be more carefully worked in the future than in the past, or those who either carelessly or selfishly abuse it will bring themselves within the reach and righteous indignation of the law.

Sanitation must wait; medical education must wait; the protection of the public from false pretensions and quackery must wait. But we shall at least be able to plead that the demands we have so repeatedly urged on the attention of the Legislature have not been satisfied; whereas the lunacy law reformers will have nothing to urge, inasmuch as their case will have been quite recently dealt with and the question settled, albeit without being answered, and it will not be likely to be speedily reopened. Therefore, so far as it goes, we prefer the cold of our own place of neglect, far outside the outermost limits of probability, to that of our friends the reformers in lunacy, who are to have their wrongs and grievances talked about and tinkered without being redressed. The outlook in medical politics is the reverse of encouraging, and almost the only redeeming feature about it is to be found in the fact that, being so utterly hopeless and bad, it surely must mend.

IN the course of a few weeks Surgeon-General J. M. CUNINGHAM, the head of the Indian Medical Service, and for many years the sanitary commissioner with the Government of India, will have completed his public career in that country. On the eve of his departure he has prepared a work on Cholera for the Government, embodying the results of his long experience and exceptional opportunities for acquiring precise information in connexion with the subject.

The work is entitled "Cholera: What can the State do to Prevent it?" In the preface the author observes: "My object is to discuss the whole question from a *practical* point of view; to examine how far the action taken by different Governments in order to arrest the progress of epidemic cholera has been productive of good and how far it has been productive of evil; and to point out, from the thirty-three years' experience I have had of the working of the sanitary department in India, what has proved to be the only effectual means of meeting the disease." Dr. CUNINGHAM, as is well known, holds what many believe to be very heterodox views on the subject of cholera; he is, nevertheless, equally well known to be a most capable public servant, and has had unsurpassed opportunities of forming an opinion of the matter with which he is dealing; and it is a decided advantage to the profession in Europe that what may be referred to as the reverse side of the shield should be held up to view by one so competent to do so. The appearance of the work, moreover, at a time when, as we were able to announce last week, a conference is to be held in Rome to consider the practical phase of the question, is very opportune.

Dr. CUNINGHAM dissents from the view that cholera is a disease of comparatively recent origin, and points out that instead of its having, as popularly supposed, started in Jessore in 1817, it is known to have existed in India at least 400 years ago; but it is only since 1868 that a systematic attempt has been made to collect statistics concerning it and other diseases in that country. As regards the so-called endemic area of cholera, it is remarked that its limits cannot by any means be readily defined on a map, as it shades off gradually in all directions, and that the prevalence of the disease in the endemic as well as in epidemic territories is very different in different years. It is, however, pointed out that the districts which suffer most are by no means those which are in most direct or constant communication with the endemic area; nor is the reverse true that those districts which escape are comparatively isolated and removed from intercourse with the endemic area. In this connexion two places are cited which enjoy a remarkable immunity from cholera—Montgomery and Mooltan, in the Punjaub; and two other places in the same province—Umritsur and Lahore—are cited as enjoying no such exemption, but from time to time suffer severely under precisely similar conditions as regards facilities of intercommunication. All four lie on the same line of railway, and bear the same relation to the traffic of the country. The direction taken by epidemics of the disease in the Bengal Presidency is stated to be always upwards, never downwards, and advantage of this circumstance is taken in regulating the movements of troops. It has never been attempted to prove that the troops conveyed cholera when travelling in a southerly direction, and this in the Upper Provinces is all the more noteworthy because the great drainage-channels, into which much of the choleraic matter must eventually find its way, run in the reverse direction of the epidemic. Railways have now placed the whole country within a few days of the endemic area, but the frequency of epidemics have by no means increased, nor is their movement more rapid, while their direction is wholly unaltered. Amongst the few places in or near India where the disease is little known, the hill station of Mussoorie is cited, which, although within seven miles of the plains, and drawing all its supplies thence, has suffered less over a long series of years than most towns in Europe.

Dr. CUNINGHAM tells us that all attempts to keep out cholera from places in India have signally failed, and so satisfied has the Government become of the futility of quarantine, that it has been altogether prohibited. All experience in India, he says, goes to show that "to impose quarantine or cordons in order to keep out cholera is a proceeding no more logical or effectual than it would be to post a line of sentries to stop the monsoon." As regards troops and prisoners, the procedure adopted is that when a single case of the disease occurs removal from the affected room or building is compulsory. If a third case occur among any body of troops, then they are immediately removed into camp. Such removal "has proved successful even when the party moved have carried their sick to the new place, and have drawn their supplies, including their water-supply, from the affected place which they had left.....Nor need any fear be entertained that the removal of bodies of men, even when suffering from cholera, will prove a source of danger to the community at large, and especially to the community to whose neighbourhood they have gone. Among the many moves made in this country there is no instance of this kind on record."

Passing on to the chapter which deals with cholera out of India, it is mentioned that reference is made to the disease in the old writings of China and Japan, and that there can be no doubt that epidemics of it occurred both in Europe and in America long before the great Bengal epidemic of 1817. With regard to the alleged statement of the conveyance of cholera from India by means of ships, it is maintained that ships sailing from that country suffer very little from the disease, and that severe outbreaks even in ships sailing from Calcutta have been extremely rare. The evidence which has been adduced in support of the disease having thus been promulgated from India is examined, and the conclusion arrived at is that "if ships from India were the common carriers of cholera, then there should be no difficulty in producing, not one or two doubtful instances, in which the evidence breaks down at once on examination, but hundreds of instances in which the evidence is clear, complete, and incontrovertible."

The visitations of cholera to Europe and America during the last fifty years are divided into three periods—1829 to 1864, 1865 to 1880, and 1880 to 1884. During the first of these periods three epidemics were recorded, all of which appeared first in the east of Russia. The materials for the history of the second period are collected from the late Mr. NETTEN RADCLIFFE'S exhaustive papers, and deal with the appearance of the disease in various European countries each year from 1865 to 1874; during 1875 to 1877 no cases in Europe have been recorded, nor were there any in 1879. In connexion with the third period, 1880 to 1884, the history of the recent epidemic is dealt with. In Dr. CUNINGHAM'S opinion, the upshot of all the evidence goes to show that during the fifty years passed under review the places which are in most direct and constant communication with India have suffered least; that since direct and constant

communication was established between India and Europe, Europe has suffered from cholera invasion less frequently than it did before; and that in spite of railways and other improved means of communication, the recent European epidemic travelled no faster than did that of 1832.

The system of "medical inspection" is briefly referred to, and considered to be useful in itself, but it is not to be depended on as a means of preventing cholera invasion. Ships coming from cholera-stricken places may be expected to have cholera sick on board. "The sick have suffered because of the influence of the place from which they have come, and the best evidence of the groundlessness of the fear attaching to them is to be found in the fact that in nearly every instance they are isolated cases, and the rest of the ship's crew have not been attacked. There is a great difference between the arrival of persons suffering from cholera and the arrival of the influence or causes which produce cholera." Reference is made to the isolated cases of the disease which occur in all countries every year—it is known to have been in Russia during the last twenty years,—but they are referred to, when not followed by an epidemic, as cases of cholera nostras. But Dr. CUNINGHAM asks, "Are isolated cases of small-pox or measles different from the numerous cases which make up an epidemic? Are they distinguished as cases of variola nostras or rubeola nostras? And yet these diseases, just like cholera, have their times of abeyance when they present themselves in solitary attacks, and their times of epidemic prevalence."

Even those who may disagree with Dr. CUNINGHAM will allow that he puts forward the points in his argument with marked ability, and all who value the thorough sifting of evidence bearing on the truth or otherwise of current medical teaching will hail with pleasure the appearance of this volume at a time when so many are prone to accept as proved and finally disposed of some of the very statements and conclusions which Dr. CUNINGHAM so vigorously assails. We regret that our space will not allow of our following the author through his examination of the theories which have been advanced in connexion with the etiology of the disease and other matters. Indeed, we have already given a longer summary of the work than we are generally able to give, simply because we feel that, being an official publication, it can reach the hands of but few of our readers, unless, as we hope, it may be republished in this country. We must not, however, omit to give the pith of what is said as to the duty of the State in connexion with the prevention of the disease, and this cannot be done better than by quoting one or two of the sentences of the author's concluding chapter: "Each country should have its own sanitary administration, which should be occupied entirely with carrying out sanitary improvements within its own boundaries, and with collecting information to show where these are most wanted and what results they have produced. If it is to be of any value, the whole practical action must be based on the great truth that the measures which will confer protection from cholera are measures directed, not against the freedom of the *person*, but against the insanitary conditions of the *place* in which he lives." Such measures will not only diminish cholera, but they will also diminish the many other diseases which, though less alarming, are by their constant drain on the population in reality much more destructive than cholera.

MR. LEAKE, the member for South Lancashire, seeing our criticisms on his speech in answer to a deputation from the anti-vaccination party in his constituency, has been at the trouble to have his words more exactly reported, and has courteously sent us a copy of the report. We have much pleasure in again reverting—though it must be briefly—to his speech, as that of a man anxious to do what is right in a public question of momentous consequence. We have no lack of sympathy, any more than Mr. LEAKE, with the difficulties of honest people who are not accustomed to weigh evidence. We shall not be far wrong if we state Mr. LEAKE'S case as follows. He cannot resist the scientific case for compulsory vaccination of children on medical and general grounds, and he has had no bad personal experience of any mischief arising from it. But he would not impose more than one penalty. He maintains that the State in many cases comes between the parent and the child, and imposes duties on the parent *nolens volens*. He thinks that much of the diminished mortality from small-pox is due to improved sanitation. He says that professional opinion as to the sufficiency of one vaccination has been disproved, that the dogma now is "vaccination every seven years," that it is empirical and all guesswork. His experience of revaccination shall be described in his own corrected words.

"His experience of revaccination was so serious and costly—the revaccination of his household in London a year or two since cost him between £50 and £70—that in future he would risk all rather than try it again on his family. Of the members of his household, twenty in number, some were unwell for months, suffering from sluggish unwholesome wounds. One child had erysipelas, one domestic scarlatina. And this under the charge of a no doubt careful physician, who employed the so-called pure calf lymph imported from Belgium. Nothing would induce him to vaccinate his family again. As it was, he took that step in deference to the fears of some members of it, and his own timidity in taking the responsibility of whatever might otherwise happen to his children."

Our answer must be as brief as the statement of Mr. LEAKE'S points. We are glad that, though in what he calls "a little bit of a dilemma," he sees his way to maintaining the compulsory vaccination of children. A visit to a blind asylum and the study of the experience of unvaccinated families in huge epidemics of small-pox will confirm his determination. His attempt to reduce the credit of vaccination by reference to improved sanitation is in our opinion a failure. The malignity of small-pox remains, and will show itself in the healthiest houses and among the healthiest people, if unvaccinated. Professional opinion is not like the POPE'S opinion—infallible; it is based on experience. The medical profession is now so open to light and so free from the influence of mere authority, that it would abandon vaccination to-morrow if it could be discredited on grounds that would satisfy common sense and a trained judgment. But with the indisputable evidence of a small mortality from small-pox among the vaccinated, and a practically absolute immunity from the disease amongst the officials of small-pox hospitals from the simple

precaution of *one successful revaccination*—vaccination every seven years has not yet reached the small-pox hospitals, though certainly one had better be vaccinated once too often than have the most modified small-pox,—there is no immediate prospect of that "general spread of intelligence and conviction" in the direction of abolishing compulsory vaccination which is likely to liberate either us or responsible public men, like Mr. LEAKE, from the duty of heartily upholding the present law, and praising GOD for men like EDWARD JENNER as the very greatest benefactors of their race. As to Mr. LEAKE'S experience of revaccination, it was not the happiest; but the lightest experience in his household of twenty of the most modified small-pox would have been more inconvenient. We do not deal with the money cost; that is a matter between him and his medical man. But we will say one or two things on the revaccination experience. It was from calf lymph. We have not yet given up our preference for lymph taken from a healthy child. But the result is much the same. The sequelæ of the revaccinations were certainly exceptional. When all is admitted, they were nothing to the sequelæ of small-pox, which we would ask Mr. LEAKE to investigate. "Domestic scarlatina" is a new disease to us, and we cannot connect it with vaccination. When Mr. LEAKE comes to weigh the sequelæ and the personal incidental inconveniences of revaccination with those of small-pox—and, by the way, in questions affecting millions we should not make too much of mere personal experience,—he will find the balance in favour of revaccination to be enormous.

Annotations.

"Ne quid nimis."

THE MEDICAL COUNCIL AND THE REVISION OF REGULATIONS OF MEDICAL EDUCATION.

THE Branch Council for England has held a meeting this week. It will be remembered that at the last meeting of the General Medical Council the revision of regulations in regard to medical education was referred for consideration to the Branch Councils. It remains to be seen whether this system of reference will work well or give more strength and precision to the work of the General Council. If we are rightly informed, the Branch Council of England does not see its way to recommend either the extension of the time of medical education or any change in the minimum age for receiving a qualification. In other words, it will recommend that the period of study should remain at forty-five months, and the age for passing not under twenty-one.

THE HOSPITAL SHIP "GANGES."

IF anyone will glance backward to the period of the Crimean war, or, even later, to that of the China war, and recall the provisions made for the sanitary and medical requirements of the sick and wounded, he cannot fail to be struck with the enormous stride that has taken place in this respect. If the so-called unification of the medical service has done nothing else, it has done this: whereas the doctors then had little or no power to have things as they wished, now they not only have the power to set forth their requirements, but, being directly brought into contact with the Admiralty officials, no pains are spared by the latter to fulfil all those requirements, and that in the most practical way. The first hospital ship fitted and equipped with a special design was the *Victor Emmanuel* for the Ashantee expedition, and from that day to this she has been the type which all other hospital ships have followed. Of course, nowadays, with iron steamers built in watertight compartments, it is impossible to obtain all the advantages of a flush hospital deck from stem to stern, with the large ports of a wooden line-of-battle ship. The hospital ship for the present expedition is a P. & O. steamer, the *Ganges*, very similar to the *Carthage* employed in the Egyptian war of 1882. The arrangements on board the *Ganges* are admirably complete—that was the opinion universally expressed by those who had the opportunity of inspecting her; and the Transport Department of the Admiralty are to be congratulated on the successful issue of their labours. As we looked at this vessel, with the Geneva Cross flag flying as her ensign, at the simplicity, effectiveness, and completeness of her arrangements, we could not avoid a feeling of gratification at the progress which had been made in providing for the sick and wounded, and at the development of views which not long ago were regarded as impracticable.

SANITARY JURISDICTION OVER DAIRY FARMS.

BRADFORD is endeavouring under an Improvement Bill to acquire certain powers over dairy farms situated beyond the limits of the borough, and we are given to understand that the Lords of Her Majesty's Council, in whom are vested the sanitary regulations as to this class of establishments object to an essential portion of the proposal. At first sight it might appear undesirable that any authority should have powers, to be enforced under a penalty clause, beyond the area of its own jurisdiction, but the circumstances under which Bradford applies for this power are so exceptional in their urgency and so fenced round by conditions that nothing but good could result if the demand were agreed to. What is asked is, firstly, that such cow-keepers or milk-dealers as supply milk within the borough limits shall, on written request from the borough medical officer of health, furnish that officer with a list giving the names and addresses of all their customers; and, secondly, that the provisions, rules, and regulations in force under the Contagious Diseases (Animals) Act, 1878, or under any Order of Her Majesty in Council, as to the good government of dairies, cowsheds, and milkshops, shall apply to any persons supplying milk within the borough, although such persons may reside or carry on their dairy processes beyond the borough boundary. Now the Privy Council do not appear to object to the first provision, and if even this should become law, Bradford may be congratulated on having made a precedent of some considerable importance. But, assuming that the list of customers should, when supplied, disclose a distribution of infection through the borough, and that an inspection of the dairy farm and premises should issue in the discovery of conditions which have led to the mischief, the urban sanitary authority remains powerless to effect any good. It is true that the borough authority may communicate the facts to the authority having jurisdiction under the Act and Orders outside the borough, but, unfortunately, when one authority makes complaint involving matters of negligent inspection or mal-administration against another authority, the only result often is that the offending authority immediately feels it its duty to put itself on the defensive, rather than to loyally aid the complainants. Besides which, the real wrong has been done to the borough, and not to the outside district, and the injured district should have some power of enforcing the alterations necessary to prevent any similar occurrence. The assumption we have made is by no means a hypothetical one. Dr. Hime tells us of nine dairy farms which, though

situated in a neighbouring rural district, sent all their milk into Bradford. All the nine premises were found to be in a most unsatisfactory condition, and in one of them a scarlatinal child and its excremental matters were found in such dangerous relationship to the milk utensils as readily to account for the prevalence of disease which had occurred in the borough, and was the immediate cause of the inquiry which had elicited the facts narrated. It will also be in the recollection of our readers that some two years ago London suffered from a severe epidemic which was traced to a dairy farm in the rural sanitary district of St. Albans, and that last year again the borough of St. Albans suffered from a similar epidemic having its source in the same district. It therefore becomes a matter of great importance to place in the hands of authorities whose districts thus become invaded some power over the source of mischief, even though it may lie beyond the area of their sanitary jurisdiction. And it must be remembered that precedents have already received legislative assent, which justify the application made. Thus, section 108 of the Public Health Act, 1875, gives distinct power to a local authority to take proceedings where a cause of nuisance arises beyond the limits of its jurisdiction. Again, under section 11 of the Vaccination Act, 1871, proceedings may be taken respecting any child not within the area for which the vaccination officer acts if either the child or its parent was within such area at the time the information was given by such officer. Here it is taken for granted that, since the offence affects or has been committed in one district, the authorities of the injured district have the power to enforce remedy or penalty. All that Bradford asks is that this principle should be extended, so that their borough may deal with the grave injury to which it is at times subjected by the importation of disease and death from dairy farms outside its sanitary limits. We trust that from this point of view, and in consideration of the important matters which have been urged in a special memorandum prepared by Dr. Hime, the Privy Council may see their way to assent to the claim of the Bradford Corporation—a claim which may reasonably be made by every sanitary authority in the kingdom.

MENINGITIS IN SCHOOL CHILDREN.

LAST Saturday Dr. Danford Thomas held an inquest on a boy aged eleven years whose death was considered to be indirectly due to mismanagement at school. The history of the case proved that the child was known to be delicate, that he had been ailing in an obscure way for some months, and had had a discharge from one ear and one eye up till the time of his death, which occurred on Thursday week, after a sudden attack of vomiting with frothing at the mouth. It was also stated that a master at the school which the boy formerly attended had been in the habit of boxing his ears for slight misdemeanours. A post-mortem examination showed that cerebral tuberculosis was the proximate cause of death. In the opinion of the medical attendant this disease had arisen from the ear mischief, whilst the latter might have been due to the boxing chastisement inflicted. To unravel accurately the evidence of causation in such a case as this is not a simple matter. Several points equally claim our attention. The delicacy of a strumous constitution is a wide term and full of meaning. Even in the absence of any other trouble it cannot be relied on to maintain itself at a fair level of health. Then there is the ear discharge, with its possibilities of infection should it continue unchecked by treatment or become obstructed in its exit. There is also the direct violence of boxing the ears, and there is the continued mental tension of school lessons, which at the age of eleven are sufficient to occupy children in good health to the extent of their capacity. Undoubtedly a blow on the ear might cause injury within it, which in turn might lead to otitis and suppuration. When this condition is established a further process of cranial disease and meningitis are sequelæ familiar to every surgeon. The tubercular complication may or may not be present. Where it does exist there is room for doubt as to how far the aural disease and the constitutional fault of the patient are respectively accountable for it. The finding of true tubercle, of which we have at least macroscopic evidence in the present case, while it by no means excludes the possibility of an origin in the absorption of morbid products in the ear, is instructive in another way. It reminds us that there is a class of children in elementary schools who have inherited a physical type which is prone to suffer in an extreme degree, not only from the shock of a local injury, but also from other forces which are then in operation. One of these has been widely recognised and met by the provision of a cheap and wholesome diet. Others, such as the want of open-air exercise and the pressure of examination tasks, are, we hope, undergoing abatement. The closing remarks of the jury are significant. After condemning the irregular mode of punishment in question, they add: "The dulness of the deceased in his schoolwork for which he was punished was due to physical causes, over which the deceased had no control."

LADY JOHN MANNERS AND TOOTHLESS PAUPERS.

LADY JOHN MANNERS, on the occasion of opening a bazaar to raise funds for a chapel in the Melton Workhouse, showed how possible it is for a lady with all the means of comfort and luxury to put herself sympathetically into the place of the inmates of a workhouse, and, as it were, feel their loneliness, their hopelessness, and the dreary monotony of their lives. It is the virtue of such sympathy as that of Lady John Manners that it does not evaporate in mere words and sentiments; it takes a practical form. One of the very last things that would occur to mere benevolent dreamers is the condition of old toothless people in workhouses, and their difficulties with a piece of tough meat, which often means that they go almost dinnerless. The amount of thought given to the appearance and efficiency of the dental system is one of the most striking points in the luxury of the age. Lady John Manners has given kindly thought to the case of poor paupers who have indifferent or inadequate teeth, and who cannot hope to be helped by a fashionable dentist. Extraction is all the dentistry for which paupers can hope. Lady John has a word for them. She proposes the more systematic introduction of mincing machines to do the work of teeth for them. The proposal is altogether admirable, and only needs to be made to be adopted by all sensible and humane boards.

HYSTERICAL PYREXIA.

ANCIENT authors used to allow the existence of hysterical fever, and though this idea has been ridiculed by modern authorities, yet recently M. Debove has advocated it afresh. He believes that he has seen several examples of it, although where febrile movements are recorded in hospitals for nervous females we might suspect the onset of tuberculous disease. A case was narrated by M. Debove, which he watched for five years after the commencement of the pyrexia. The patient was twenty-four years of age, and had suffered from neurotic disturbances ever since the age of seven years. Three years ago she suffered from a severe febrile disturbance, which exhibited the three stages of cold, heat, and sweating, very clearly; since that time the temperature, taken at regular intervals, has never been below 100° F., and two or three times a week the temperature has intermittently reached to nearly 104° F. The possibility of malaria was excluded by M. Debove, on the ground that the spleen was not enlarged, and that quinine

had no influence over the fever. Deception seemed to be out of the question, as M. Debove himself took the temperature on several occasions. The question was discussed at the Académie de Médecine whether in hysterical individuals the heat centres might not be functionally disturbed, thereby occasioning the alterations in the normal heat of the body—whether, in fact, hysteria of the thermic centres is possible.

THE SANITARY ADMINISTRATION OF WOOLWICH.

SINCE our brief comment in our issue of the 7th inst. as to certain points in the sanitary administration of Woolwich, we have had an opportunity of perusing the recent official report on the district. Woolwich occupies an exceptional position as regards its sanitary administration. From 1805 to 1852 its sanitary affairs were administered under a private Improvement Act; in 1852 the Public Health Act, 1848, was applied to it by means of a Provisional Order; and in the Metropolis Local Management Act, 1855, Woolwich was for certain matters scheduled as a metropolitan parish, and thus came under the Metropolitan Board of Works, but a saving clause exempted the locality from other powers conferred under the Act, and so the Local Board of Health formed under the Act of 1848 is still retained. But because the district is in some respects metropolitan, neither of the Public Health Acts of 1872 or 1875 applies to it; and it thus comes to pass that Woolwich is neither under the metropolitan sanitary legislation nor under that applicable to the country generally. One chief anomaly arising from this singular position is that Woolwich is under no obligation to appoint a medical officer of health, nor to report to the Local Government Board as to its sanitary state, and under these circumstances that Board have, through their inspector, Mr. Spear, instituted an inquiry as to the state of the district and its sanitary administration. In some very important respects Woolwich has been found to be by no means behindhand. For certain purposes, as, for example, in connexion with works of main sewerage and the regulation of the structure and foundations of new buildings, the district has been cared for by the Metropolitan Board of Works, and its water-supply is from London Companies. It has also striven to meet the want of a medical officer of health by securing the services of an officer who is really competent in his proper capacity, and who holds the dual appointment of surveyor and inspector of nuisances; it has inaugurated a voluntary system of notification of diseases; and it carries out certain provisions against infection either without medical aid and advice, or by means of such aid as the inspector of nuisances may think desirable. The local board further express themselves to be ready to appoint a medical officer of health on any occasion of emergency in connexion with epidemic disease that may arise. All this is much to their credit, but still it is evident, both from a consideration of all the circumstances, and also from the details of Mr. Spear's report, that this does not suffice. Such an administration as exists cannot possibly give to any competent officer of the authority such information as is needed in order to take skilled account of the sanitary requirements of the district; and for the purposes of the prevention of disease, it is above all things needful that detailed medical knowledge of the sanitary circumstances of a district should be at any moment available. If cholera were, for example, to extend to Woolwich this year, can it for a moment be supposed that a medical officer of health newly appointed in the face of such an emergency would compare, in point of efficiency, with one who had in an official capacity, and by the aid of carefully compiled statistics and frequent sanitary inspections, already made himself master of the district and of its sanitary wants? We would strongly urge the Woolwich Board of Health no longer to hesitate to make a really proper appointment, and to seek the permanent services of an officer capable of advising them in all health matters concerning this very important district. The need for a medical officer of health in every sanitary district has been regarded as imperative by the public and by the State, and the mere accident of having a peculiar and exceptional standing as to their sanitary law should not debar the inhabitants of Woolwich from having the same class of skilled services which is deemed necessary for all other districts in the kingdom.

THE PEABODY BUILDINGS IN 1884.

THE trustees of the Peabody Donation Fund have issued their twentieth annual report relating to last year. The amount spent upon land and buildings during the twenty years has considerably exceeded a million sterling, with the result that 10,144 rooms, besides bath-rooms, laundries, and wash-houses have been provided for the artisan and labouring poor of London, and were at the end of last year occupied by a population of 18,453 persons. The report states that the average weekly earnings of the head of each family in residence at the close of the year was 23*s.* 8*d.*; the average rent of each tenement was 4*s.* 8*d.* per week, and of each room 2*s.* 1*d.* The vital statistics of the resident population of the Peabody Buildings afford trustworthy evidence of satisfactory sanitary condition. The birth-rate was equal to 44·6 per 1000, and exceeded by 10·9 the rate for the whole of London. This high birth-rate indicates an age constitution of the population which should give a low death-rate. The recorded death-rate, after correction for the deaths of residents recorded in hospital, was 19·1, and was 1·2 below the general London rate. Infant mortality, measured by the proportion of infants under one year to births, was 138·7 per 1000, and 13·7 below the mean rate in London. These figures are somewhat more favourable than those recorded in recent years. It is necessary, however, to point out that mortality statistics of improved or model dwellings are of somewhat doubtful value for comparative purposes. The inhabitants of such dwellings consist for the most part of a "selected" population; selected indirectly as being healthy, steady, thrifty, and respectable. The number of applications for each vacant tenement facilitates this selection. Moreover, it must be remembered that as these tenants break down in health, or capacity for work, they cease to be tenants, and often drift through other lodgings to the workhouse or hospital. After due allowance, however, for all these disturbing influences, the trustees may be congratulated upon the evidence they are able to report of the health of the residents of their buildings during last year.

TABES DORSALIS AND SYPHILIS.

PROFESSOR A. EULENBERG (Virch. *Arch.*, 99, i.), returning once more to the question of the relation between tabes and syphilis, arrives at the following conclusions. There is apparently an absolutely and relatively large percentage of tabetics who have been syphilitic; their number is notably larger than a few years ago was generally suspected. The precise relation which syphilis bears to a subsequent tabes is not known; probably it acts only as a debilitating, disposing factor, like many other agencies; but possibly in a certain number of cases syphilis may be the direct cause of tabes. However that may be, it is hardly possible that syphilis can be considered as the sole, or even as the most frequent and important, cause of tabes. Those cases of tabes which are preceded by syphilis exhibit no constant and characteristic symptoms, and in their course are not to be distinguished from other (non-syphilitic) cases. Neither is there any marked or characteristic difference shown in the two cases as to prognosis and treatment. Under certain circum-

stances, cases of tabes with syphilitic antecedents may improve as well without antisyphilitic treatment as under it, may even become quite cured; whilst, as a rule, specific treatment shows no result, or only a transitory one. Although for some years past this question of the etiology of tabes has been much investigated, no definite solution has been arrived at; nor is it yet determined whether any essential practical gain as regards the treatment of the disease has ensued from such inquiries.

ALLEGED DANGERS IN THE USE OF CORROSIVE SUBLIMATE AS AN ANTISEPTIC AGENT.

DR. FRAENKEL of Hamburg draws attention (Virch. *Arch.*, 99, ii.) to an almost unsuspected danger arising from the too free use of corrosive sublimate as an antiseptic agent. His remarks are in the first place based upon a case recorded by Stadfelt of death with dysenteric symptoms following upon intra-uterine injection of a solution of sublimate (1 in 1500) after adherent placenta, and are supported by the results of post-mortem examinations of surgical cases in which this solution was employed. In all these cases (fourteen in number) severe ulcerative lesions were found in the large intestine, but Dr. Fraenkel admits that in only two of these could the lesion be said to have caused the death of the patient. The appearances presented by the diseased bowel resembled those of acute dysentery—viz., more or less extensive areas of necrosis of the mucous membrane, with intense surrounding inflammation. He combats the notion that the intestinal lesions depended on septicæmia, mainly on the ground that in no case were any other of the lesions characteristic of septicæmia or pyæmia present, nor did the cases run the clinical course of blood-poisoning. Although the paramount value of corrosive sublimate as an antiseptic must be admitted, its employment is nevertheless not free from risk. Its immoderate use as an external application is liable to excite the diphtheritic-like inflammation of the large and sometimes of the small intestine, which is recognised clinically by tenesmus, colic, and bloody stools. But so far the renal changes supposed to be characteristic of sublimate poisoning have not been observed in surgical practice. The intestinal affection is most liable to occur in individuals whose nutrition is defective, or who are very fat, especially those with fatty hearts; and particularly if the sublimate has been in contact with large exposed and absorbing surfaces, as the peritoneum or uterus; therefore care should be taken to use only the weakest solutions consistent with their antiseptic property, and especially not to use them too frequently as intra-uterine injections.

HEALING BY FAITH.

IT is not our purpose to deny, or even to question, the verity of cures "by faith." The "mind" so acts on the body, and the brain plays so important a part in the nervous system, by which the whole organism is energised and controlled both in regard to its functions and nutrition, that it is not only quite possible, but an absolute fact, that many maladies which are not so far advanced as to be dependent upon changes in structure, or "organic diseases," may be remedied by, or through, the agency of the mind. We will even go so far as to affirm that a very large proportion of the ailing might be, and probably would be, sound if only they were sufficiently strongly impressed to believe themselves to be so. This influence of the mind on the body has been the stronghold of quackery from the earliest times, and "faith" is as powerful an influence for good or evil now as it has ever been. Such "miracles" as the Salvationists are working, with their prestige among the emotional classes, whether illiterate or well-informed, have uniformly signalised the commencement of a new era in religious enthusiasm. When the first enthusiasm subsides, "miracles cease" of physico-mental necessity. The large class of so-called hysterical, cataleptic, and even epileptic affections are distinctly amenable to this influence; so are those nervous disturbances and derangements which consist wholly or chiefly in disorderly activity, as distinguished from actual disease. The mimetic maladies, of which there are always a very large number of cases, are, of course, amenable to the curative influence of faith. Outside these classes, however, stand a multitude of badly managed or misunderstood cases which only need to be placed on a new footing—it matters little what—to get well. A wondrous cloud of ignorant prejudices still hovers over many districts as to the curability or hopelessness of special diseases which are better understood and more successfully treated—on common-sense principles—in the centres of knowledge. For example, we know of localities and affections which, being associated, produce the most dire delusions as to the length of time bones usually take to unite in healthy subjects; and how far coughs and other distressing maladies are, or are not, under the control of the will. In such combinations of fact and fiction it is easy to get miracles out of such common matters as the union of the accurately applied ends of a fractured radius in three or four days! There is not a word to be said against "healing by faith." Every busy practitioner has cases under his observation that he would be heartily glad to find so powerfully affected that they could be cured even by this agency. All we are anxious to point out is that an intelligent lay press ought not to lend itself to the promulgation of nonsensical beliefs and impressions. Of course, it is true that many of the poor people who are reported to be "cured" are actually benefited, and by their faith. This is a fact, and there is no sort of reason why the benefits received should not be permanent. If the subjects of these cures are thankful to the Giver of all good, that is not a matter to make merry about. It is as it should be. We are glad of their gain and pleased to find them moved to gratitude. Meanwhile, if these "cures" need be discussed, let the comments made be neither irreverent, offensive, nor puerile. The *modus operandi* of such recoveries is perfectly well understood, and there is nothing either specially noteworthy or wonderful about them.

HOSPITAL SHIPS.

AT a meeting of the Hospitals Association, held on Wednesday, February 18th, Sir Edmund Hay Currie in the chair, Dr. Murray Braidwood read an interesting paper on "Hospital Ships," which he stated should be specially constructed and adapted for the treatment of sick and wounded. He argued that the hospital was necessarily very different from an ordinary dwelling-house, and the conversion of the latter into the former was at the best unsatisfactory; so, also, it was equally unsatisfactory to attempt to use a ship constructed for other purposes for the reception and treatment of the sick. From the medical point of view there is much to be said in favour of Dr. Braidwood's suggestion, but the great difficulty which has to be met is that of expense; the opportunity for the use of such vessels in time of war is, we are glad to say, rare, and it is doubtful if the Government could be induced sufficiently to recognise the advantages they would confer by devoting to this purpose ships which would not be useful for other purposes in the interval. That the civil population would, under certain circumstances, find such ships useful is proved by the action of the Metropolitan Asylums Board in providing the *Castalia* and other vessels for the isolation of small-pox; but at the present moment we are not in a position to contrast the expenses incurred with those of the erection of hospitals on

shore. At the meeting a plea was made for the provision of proper accommodation for the sick on board the large ocean vessels which every week leave India for Europe, carrying with them a number of invalids who, for the sake of healthy passengers not less than for their own welfare, should receive special consideration. With this demand we fully sympathise. A few of the shipping companies, but not all, have recognised its need, and we would therefore urge it upon all who may have the duty of arranging for the conveyance of the sick.

ENTERIC FEVER IN NORWICH.

FROM recent weekly returns of the Registrar-General it appears that the annual death-rate in Norwich averaged 28·7 per 1000 during the first seven weeks of this year, exceeding the mean death-rate during the same period in the twenty-eight large English towns by 5·7. The rate in Norwich from the principal zymotic diseases, moreover, averaged 3·7 per 1000, against 2·2 in the twenty-eight towns. This excess of zymotic fatality in Norwich was mainly due to the prevalence of "fever" and of whooping-cough, to which 21, and 15 deaths, have been respectively referred since the beginning of this year. The first death from "fever" was registered in the second week of this year, whereas in the five following weeks the deaths referred to this heading averaged 4 per week. Although the form of "fever" is not distinguished in the Registrar-General's weekly return, it may safely be assumed that these figures indicate an outbreak of enteric fever in the city. It may be noted that the recorded death-rate in Norwich last year did not exceed 21·2 per 1000, and this rate, if corrected for the abnormal age distribution of its population, is reduced to 20·2, very slightly exceeding the rate in the whole of England and Wales, which was 19·6. The deaths from "fever" in Norwich during the fifty-three weeks of last year were 31, giving a rate from this disease very little in excess of the mean "fever" rate in the twenty-eight large towns dealt with in the weekly return. Perhaps the most unfavourable feature in the mortality statistics of Norwich last year was its high rate of infant mortality; this was equal to 187 deaths under one year per 1000 born alive, whereas the proportion in the twenty-seven other towns ranged from 128 in Portsmouth to 226 in Leicester, and averaged 168. Norwich has persistently shown excessive infant mortality in recent years.

WAR WITH NATURE.

THE year before the Franco-Prussian war General A. von Roon, Prussian Minister of War, caused to be published and jointly edited with Oscar Peschel a treatise on ethnology. He had been mainly instrumental in the creation of the new German military system, and desired to cultivate in the German army a knowledge of the natural laws by which races tend to spread and diffuse themselves. Some such study would be useful now to teach our soldiers, and especially our politicians, the uselessness of waging war against the overpowering forces of nature. It is an exciting political question just now whether the Soudan should be permanently occupied or not. There will be ample British blood shed, and slaughter enough of the semi-civilised races of the Soudan now struggling with religious fanaticism over this question. We do not doubt the ultimate triumph of our arms in the field, but we do doubt the possibility of any permanent occupation of the Soudan. No European race has yet succeeded in colonising the valley of the Nile. All attempts to propagate Europeans in this district have failed, though every civilising nation has tried it in turn. The people now are the same as in the days of the Pharaohs, and so they will remain, whatever statesmen and warriors may desire to the contrary. Natural laws affecting the diffusion of races will not yield to military or political exigencies. The sooner this truth is realised the better. It was an axiom of the great Napoleon after his Egyptian campaign not again to wage war with a desert.

FREE NURSING FOR INFECTIOUS DISEASES.

LAST week we made some observations on the valuable aid which is rendered to medical practice among the poor, except, we understand, as regards infectious fever cases, by the North London Nursing Association. About the same time the public were informed through the daily press of the working of another Society with allied though not identical aims—the Westminster Sanitary Aid Association. The purpose of this body is to make itself acquainted with the needs of the poor in regard to the preventive hygiene of infectious diseases, and to help them to carry out the measures required for disinfection. It is obvious that between the proper spheres of action of these useful agencies there is still a gap which charity would do well to fill, inasmuch as the nursing of the most prevalent and communicable fevers receives no attention from either. Many such cases, no doubt, find their way into hospitals; others not so severe are tended to a successful issue by careful parents. Most of the latter class, however, would benefit, and some above all demand that skilled attention which the practitioner can only prescribe, and which the trained nurse alone can efficiently render. Could not some plan of action be devised by one or both of the Associations we have mentioned by which this needy section of sufferers might be brought within their care? An increase in the nursing staff would of course be required, but not, perhaps, to so great an extent as might at first appear necessary. It would be only right to assign certain nurses to wait upon each kind of infectious disease, visiting the patients in turn; and in this way a small staff would be able, in the course of their daily rounds, to superintend a considerable number of cases, with little risk of carrying infection from one to another.

SMALL-POX IN ISLINGTON.

MR. STONELAKE has done good service in directing the attention of his fellow guardians to the proportions of the small-pox epidemic in Islington. A considerable number of cases had been traced to a potman in a small public house, who continued to carry and serve customers while actually suffering from the disease. This case should be submitted to a magistrate. Islington has not appeared creditably in times of epidemic small-pox. One great metropolitan epidemic, that of 1876-7, seemed to originate in Islington, and to be very inadequately managed at the outset. Whose fault is it? The guardians are at any rate now aware of the facts. The mere issue of handbills is not enough. Disinfectants are a delusion. A house-to-house visitation should be immediately established. Every case of small-pox is a discredit either to parents or the public authorities, or to unrevaccinated adults.

ERYTHROMELALGIA.

A CURIOUS case which had been under the care of Dr. Weir Mitchell was exhibited at a meeting of the Philadelphia Neurological Society. The patient was a man aged fifty-three, a blacksmith by trade. Rather more than three years ago the first symptoms of the affection appeared in the form of pain in the inner side of the second toe of the left foot. A year later the third toe was affected, and still later the fourth and little toes, and four months ago the great toe became involved. The toes were all affected in the same manner; first, a burning sensation, followed by an aching pain, was experienced, and some weeks

after discolouration of the affected toe set in. The toes of the right foot also became affected, though to a less degree, about a year ago. The pain is not worse in wet or cold weather, but it is more severe at night when the feet get warm. Occasionally twitchings, chiefly nocturnal, have been felt in the calf of the left leg. The second left toe was amputated at the proximal joint; the wound healed slowly and the pain was relieved in all the toes. At the present time all the toes affected are discoloured; the left foot up to the ankle is covered irregularly with reddish patches, which disappear on pressure, and are more or less sensitive. Sharp shooting pains about the arms have been experienced from time to time. The nature of the case seems somewhat obscure; it may possibly have alliances with the protean conditions which accompany the first stages of tabes dorsalis.

THE LATE GENERAL STEWART.

WE have yet to learn the full particulars of the wound received by General Stewart, and the progress of the events which ended in his death. The fears we expressed in a recent annotation have been realised. We should surmise that the bullet, which entered at the groin, passed into his pelvis, and that the long track it left was not rendered or maintained aseptic. The occurrence of fever, which appears to have rapidly terminated fatally, was due in all probability to some septic change set up in the wound. This, as we previously explained, was a danger to which he was exposed until cicatrisation was complete, and against which it is specially difficult to guard in military practice. We trust that full particulars of the wound, its complications, and the treatment adopted will be forthcoming.

FIBRO-ENCHONDROMA OF THE TONSIL.

DR. ANGELO CHIOLINI reports in the *Gazzetta degli Ospitali* (15th inst.) the case of A. V——, aged thirty-three, who was admitted into the clinique of the University of Pavia, under Professor Bottini, on Nov. 24th, 1884. Three years previously, the patient, without apparent cause, began to experience buzzing and singing noises in the right ear, with slight deafness on the same side. One medical practitioner referred the symptoms to simple otitis; another, who was consulted a month later, finding the right tonsil somewhat enlarged, applied tincture of iodine to it, and administered iodide of potassium internally. The persistent increase of the tonsil successively interfered with respiration, deglutition, and speech, and the patient was pale and emaciated when she placed herself under Professor Bottini's care. She was then quite deaf in the right ear, and swallowed with great difficulty. A small very hard tumour, of the size and shape of an almond, was noticeable just above the right angle of the lower jaw, without implicating the skin. Just below was another, of roundish shape, the size of a walnut. A small movable elastic body occupied the sulcus between the two tumours, which on deep palpation seemed joined in one mass. On looking into the patient's mouth, four-fifths of the isthmus of the fauces from right to left were occupied by a tumour, which extended forwards over three-fourths of the palate, and downwards and backwards beyond reach of the exploring index finger. Want of space rendered laryngoscopic examination impossible. The tip of the uvula touched the left tonsil, which was perfectly healthy. The tip of the little finger could with difficulty be introduced into the isthmus of the fauces. The tumour was very firm and painless, and the part of it visible in the mouth was round and granular, but not ulcerated. Having diagnosed the neoplasm as a very rare specimen of large fibro-enchondroma of the tonsil, Professor Bottini resolved on its removal. This was effected on the 9th of December last. The patient being seated on a chair, her head was held back by one assistant, while another depressed the tongue and held the mouth open. Professor Bottini, seated in front, then made an incision with a straight bistoury along the roof of the mouth and through the soft palate. A considerable portion of the tumour, thus exposed, presented a white mother-of-pearl appearance. Enucleation was effected by the finger, with external pressure and forceps traction from within. The wound in the soft palate was united with twelve points of suture, and the mouth washed out with a 5 per cent. solution of sulpho-carbolate of zinc. The operation occupied half an hour, and was completed without hæmorrhage. Convalescence was rapid and uneventful. The wound was found to be perfectly healed on the second day, when the sutures were removed. The breathing, deglutition, speech, and hearing became natural, and the patient was quite well on the eighth day. She left the clinique four days later. The tumour, on reuniting the fragments, proved to be of the size of a large orange; its surface was lobulated and exceedingly hard. On fracture, the surface was found to be of mother-of-pearl colour in some parts, and yellowish-red in others. The diagnosis of fibro-enchondroma was accurately verified by microscopic examination. The cells in some parts were identical with those of normal cartilage.

ADULTERATION IN AMERICA.

WE are glad to learn that a "Society for the Prevention and Suppression of Adulteration of Food, Drugs, Medicines, Liquors, &c.," is about to be organised in America. It is surprising that this most important subject has hitherto received so little attention in a country which, young as it is, has produced a people whose ingenuity, activity, and inventiveness are almost proverbial. The fierce competition that inevitably arises from these qualities is, we fear, only too likely to develop such mean and injurious devices as adulteration. At present there has been but little legislation on this matter in the United States. Very few cases have, we believe, been brought before the courts of law, and these have not been for adulteration proper but for the sale of diseased meat, &c. It is high time that our Transatlantic cousins should give this subject the serious attention it demands. THE LANCET can claim to have rendered to humanity good service in this cause; whilst, therefore, congratulating the promoters of the Society and wishing them success, we would refer them to the Analytical Sanitary Commissions inaugurated by us in 1851.

THE PATENT MEDICINES STAMP TAX.

MR. WARTON has given notice in the House of Commons that on March 17th he will call attention to the conduct of the Government with regard to poisonous patent medicines, and move a resolution on the subject. It will be remembered that as long ago as the beginning of last August the Chancellor of the Exchequer stated that he had asked the Board of Inland Revenue for a report, which he promised to "study with care." It will be interesting to hear what has been done in the matter.

BURGLARS AND DOCTORS' HOUSES.

SOME burglars have recently made the neighbourhood of Woolwich the scene of their exploits. It is believed that these gentry usually are reluctant to meddle with the houses of medical men, from the risk they might run of being disturbed by the doctor's nocturnal movements. In this instance, however, they not only entered the house of a well-known and much respected practitioner, but, curiously enough, ignored the fact of his being surgeon to the police, so that they ran the risk of being caught at their work by a policeman coming to ring the night bell. At all events,

they seem to have been disturbed in some way, for, though they disarranged a number of articles of furniture, we are glad to learn that nothing of any importance has been missed. Some arrests have been made on account of other burglaries in the neighbourhood.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

THE annual meeting of this Society will be held on Monday next, March 2nd. It has been arranged that a discussion on Cholera shall be commenced on March 24th, when the President, Dr. George Johnson, will open the debate. We believe that Drs. Klein and Gibbes will take a prominent part in the proceedings.

PORRO'S OPERATION.

Il Morgagni (7th inst.) reports a case of Porro's operation, successful to mother and child, which was performed at Gubbio on the 15th ult. by Dr. Lodovico Vincini. The patient, M. M——, aged forty, was a rachitic primipara, with extremely contracted pelvis. She was in the ninth month of pregnancy, and had been twelve hours in labour, when chloroform was administered. The removal of the uterus and appendages occupied fifty-five minutes. The spray was not used, but a strictly antiseptic dressing applied. The patient quickly recovered from the anæsthetic, and in twenty-four hours was in the most favourable state. This continued, and the child, a female, is also well.

INTERNATIONAL MEDICAL CONGRESS.

THE arrangements for the meeting of the International Medical Congress in Washington in 1887 are in a forward state of preparation, and we believe the officers of the various sections have been nominated. Dr. Flint is to be the President of the Congress; certainly no one could be chosen who would more worthily fill the chair.

ASEPTIC SILK.

MR. H. W. FREEMAN, of the Royal United Hospital, Bath, has been using chromic acid silk sutures in abdominal sections to bring together the abdominal parietes, also in perineorraphy and in excisions of the breast, and he claims that deep sutures may be left in the abdominal walls for three weeks, in the perineum for a fortnight, and in the breast for the same length of time, without the slightest change occurring in the texture of the silk or sepsis in the course of the suture. China twist seems to be hardened by this process and rendered impervious to the surrounding secretions. The silk is prepared by boiling it in a 2 per cent. solution of chromic acid for ten minutes and allowing it to soak for twelve hours subsequently in a 1 per cent. solution. A stronger solution destroys the silk and renders it brittle.

THREE ATTEMPTS AT HANGING.

IT was simply just to commute the sentence of death passed on John Lee, the butler, convicted of the murder of Miss Keyse at Babbicombe in November last. The bitterness of death has been inflicted on that condemned man at least three times, and the law ought to be satisfied. The mismanagement of the execution was complete—indeed, so complete as to be startling; and if it should hereafter be found that the disavowal of guilt to which Lee still adheres is truthful, there will not be wanting many to allege that the execution was prevented by some supernatural agency. It is inconceivable that the "drop" could not be made to fall when the bolt was drawn! It was surely tried before the execution, and presumably it was again tried once or twice between the futile attempts to hang the culprit. What are we to understand? The interposition of the Home Secretary was clearly called for, and it would be inhuman to hang the convict now; but there ought certainly to be a searching inquiry into the causes of the failure.

UNSATISFACTORY INQUEST AT ST. DAVID'S.

A VERY inadequate inquest at St. David's is reported on the body of a young woman who died in convulsions, and was found post mortem to show indications of recent delivery. Her mother had suspected pregnancy, but the deceased had persistently denied it. The former said that at the time of her daughter's death she had no reason to believe she had been delivered. Mr. Foley had seen the deceased, and formed the opinion that she had been delivered five or six days previously, and that the confinement was not the cause of death. No trace of the child has yet been found. The jury returned a verdict "that the deceased died from puerperal convulsions." We are rather accustomed nowadays to inconclusive inquests, but surely no coroner will be satisfied to leave an inquiry where this is left.

EXPERIMENTAL PRODUCTION OF CHOREA.

WE are informed that Dr. Angel Money will shortly read a paper at the Royal Medical and Chirurgical Society on the above subject. It is said that his experiments prove that chorea can be caused by capillary embolism of the central nervous system.

MR. HENRY LOMB, of Rochester, N.Y., has offered through the American Public Health Association the sum of $2800 to be awarded as first and second prizes for papers on the following subjects:—1. "Healthy homes and foods for the working classes." 2. "The sanitary conditions and necessities of school-houses and school-life." 3. "Disinfection and individual prophylaxis against infectious diseases." 4. "The preventable causes of disease, injury, and death in American manufactories and workshops, and the best means and appliances for preventing and avoiding them." The first prizes consist of $500 and the second of $200.

IT has been decided to offer £100 to the Senate of London University towards the foundation of a Rabbeth Medal in commemoration of Dr. Rabbeth, who lost his life through an attempt to relieve the sufferings of a child dying of diphtheria in the Royal Free Hospital. The father of Dr. Rabbeth having undertaken to found the proposed scholarship at King's College in memory of his son at his own expense, the committee of the memorial fund have resolved to divide the funds which may be at their disposal on the 31st of March between the King's College and Royal Free Hospitals towards the endowment of two children's cots.

IN reference to the criticism in THE LANCET last week on the cholera hospitals in Bombay, we are pleased to learn from our Bombay contemporaries that some other site instead of the compound of the European General Hospital is to be selected for the erection of a cholera hospital for the natives. Though the Government do not appear to have been moved by the potent reasons urged by the Surgeon-General of the Presidency, still we cannot but hail the change, which is, indeed, in the true interests of humanity and preventive medicine.

IN an original article contributed to the *Gazette Hebdomadaire des Sciences Médicales de Montpellier* M. Grynfelt has advocated the use of injections of hydrochlorate of cocaine to facilitate catheterism.

MESSRS. CROOKES, ODLING, and TIDY, in their report on the composition and quality of daily samples of the water supplied to London for the month ending Jan. 31st, state that all the samples examined were clear, bright, and well-filtered. The mean quantity of organic matter in Thames-derived water supplied during the past month was 0·137 part, and the maximum in any one sample was 0·182 part, in 100,000 parts of the water, this quantity corresponding to a little over three-tenths of a grain of organic matter per gallon.

STUDENTS of pathology will be glad to learn that there has just appeared the final section of Professor Ziegler's admirable text-book on Pathological Anatomy. The division contains sections on the eye and ear, on the bones and joints, muscles, and male and female generative organs, as well as the mammary gland. The whole work contains 1576 pages, and is illustrated by no fewer than 357 woodcuts, nearly all of which are original. Dr. Macalister's translation will also doubtless be soon completed.

IN the Prussian Parliament on the 23rd inst. Professor Virchow and other liberals took advantage of the debate on the Estimates for the Ministry of Public Worship to direct public attention to the recent appointment of Dr. Schwenninger to the chair of Dermatology in the Berlin University, an appointment which they characterised as an arbitrary act, tending to degrade the University and corrupt the public conscience.

MR. EDWARD STANFORD, of Charing-cross, has just issued a popular map of the seat of military operations in the Soudan; also a facsimile of a map drawn with great neatness and accuracy by General Gordon, March 17th, 1874, of his route from Suakim to Berber and Khartoum. The innumerable admirers of the lamented General will doubtless eagerly possess themselves of this interesting memento of the deceased hero.

THE Twickenham Local Board sent a deputation last week to the Home Office, complaining of the condition of the Thames, both on account of the diminution of the water and the accumulation of mud caused by metropolitan sewage. The Under-Secretary assured them that the Home Secretary was exceedingly anxious to do what he could, both with reference to the water-supply and the state of the Thames.

PETITIONS have been addressed to the Home Secretary by the medical practitioners of Derby, Middlesborough, Stockton-on-Tees, Sunderland, South Shields and district, Newcastle-on-Tyne, and Durham and district, calling attention to the recent conviction of Dr. Bradley, and asking the right hon. gentleman to exercise his prerogative on Dr. Bradley's behalf.

THE Local Government Board have determined not to renew the existing orders prohibiting the importation of rags from France and Italy unless there should be any reappearance of cholera on the Continent. The orders, therefore, lapse at the end of the present month.

IN the actions brought by Mr. Hasker against Drs. Savage and Wood, medical officers of Bethlem Hospital, for assault and false imprisonment, and against Dr. Goldsborough for trespass, libel, and false imprisonment, the jury returned verdicts for the defendants.

THE attempts to grow the eucalyptus on the Assam hills, says the *Indian Medical Gazette*, have not been successful.

M. MARTINEAU has recently treated suppurating buboes by means of the thermo-cautery, whereby an ulcer is formed which tends to heal rapidly.

ALL the precautionary measures decreed by the Swiss Government during the prevalence of cholera last year in Southern Europe will be abolished from March 1st.

MR. G. BAINBRIDGE has been appointed to act as senior surgeon to the Jamsetjee Jeejeebhoy Hospital, Bombay, during the absence on furlough of Mr. W. Gray.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

Official Report on the Epidemic of Enteric Fever at Beverley.[1]—The outbreak in question commenced suddenly in the third week in June last; it increased rapidly and reached its highest point in the week ending July 12th, when twenty-nine families were freshly attacked. In a population of about 11,500, as many as 231 cases occurred before the end of August, and of these 12 died. The disease appeared in all parts of the town, no special locality or class of persons being affected more than others. In considering the cause of the epidemic, Dr. Page was soon able to eliminate the question of milk pollution; the condition of the sewers and drains was so defective as to give ample facilities for the spread of the infection, but it could not be held accountable for the origin of the outbreak. The water-supply, however, came strongly under suspicion. Of 2800 houses in Beverley, 185 are supplied by the Beverley Waterworks Company, the remainder being dependent upon local wells, and it was ascertained that of these 185 houses as many as 32 per cent. had been attacked; whereas of the other households having a different supply only 2·5 per cent. were attacked. The fifty-nine houses referred to were scattered all over the borough, and all they had in common was their water-supply. Some persons, too, who lived where private wells were used, but who had drunk the company's water at places where they were employed, also sickened; and it was soon obvious that there was strong *primâ facie* evidence implicating the company's service. In seeking the method by which pollution of this water could have taken place, the question of contamination in the mains after the supply had left the company's works came under consideration, and the existence of leaky sewers in proximity to some of the mains, as also other circumstances, make it possible that some contamination may have arisen during occasional intermissions in the service; but the character of the epidemic was opposed to this being the cause of this special outbreak. The well at the company's works lies close to a seven-acre field, on which is distributed in various ways the sewage of the East Riding Lunatic Asylum. Broad irrigation of the sewage takes place at intervals, and the last occasion on which it was practised before the epidemic was from the middle of April to the middle of June. The soil here is clay overlying chalk. Examination of the soil around the company's main near this point failed to detect any soakage of filth or any leaky joints; but that which was evidently most suspected was percolation along the sides of the well shaft through the upper chalk directly into either the well or the reservoir in which the water was stored. With a view of testing the possibility of such an occurrence, some two hundred gallons of creasote were added to the contents of the neighbouring sewage settling tank and cesspit, and these were then discharged on to the irrigation field. This experiment was without result, but Dr. Page adds that he has since ascertained that the choice of creasote

[1] To be purchased of Knight and Co., 90, Fleet-street; Shaw and Sons, Fetter-lane; Haddon, Best, and Co., West Harding-street; and P. S. King and Son, King-street, S.W.

as a test for his purpose was open to objection, for creasote, passing through a soil charged with matters derived from sewage, might either be unable to reach the well at all, or it might only reach it in a condition in which it was unrecognisable. That sewage matters can penetrate long distances cannot be doubted after Haegler's account of the Lausen epidemic, and if the sewage in this instance made its way into the Beverley water, it did not lack the possibility of containing the specific contagium, for enteric fever had prevailed at the asylum in the preceding March and April, and the interval which ensued between the latter date and the outbreak of the disease amongst the company's water consumers might easily be accounted for by conditions affecting the rate of natural discharge in this particular soil, especially during a period of scanty rainfall. The epidemic was complicated by an outburst at the asylum itself, the disease there reaching its height between July 12th and 19th. Locally this was at first set down to extension from the first cases in the previous months; but the suddenness of the attack, taken together with the date of its occurrence and its character generally, led Dr. Page to conclude that, the same water being in use in the asylum and in the town, the cause of both outbreaks was the same. Much was made during the course of the epidemic of the results of chemical analysis of the company's water. Analyses were made on May 31st and July 19th, dates which are described by Dr. Page as being on the very borders of the period when the water must have been acting as the epidemic agent. The water was always spoken of in unqualified terms of approval, but previous experience of the failure of chemical tests to detect the existence in water of infective material deprives even the most satisfactory analyses of the weight which might otherwise have been attached to them in this respect. The actual point at which contamination of the town water can have taken place was not made out; but apart from this, there can be but little hesitation in accepting the conclusion that the Beverley water did receive infection, and that the disease was distributed in the town by its means. It is also certain that the conditions which existed in the immediate vicinity of the well, main, and reservoir, and which are shown in a lithographic sketch, are such as should not be tolerated in the neighbourhood of works from which a public water-supply is delivered; and although Beverley has bought its experience somewhat dearly, we are glad to be able to add that, as the result of the epidemic, this experience is about to be acted upon, for it has been decided to remove all sewage irrigation away from the field and the filter-beds which are contiguous to the premises belonging to the Waterworks company.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Weston-super-Mare Urban District.—This district had in 1884 a death-rate of 16·2 and a birth-rate of 23·9 per 1000. The list of deaths, however, includes the cases of nine visitors. Scarlet-fever has occurred sporadically at intervals, twenty-five cases coming under notice. Six cases of enteric fever were also known of, but most of them were imported. Unfortunately, local wells are still resorted to, and this liability to pollution is shown by the fact that of fourteen samples sent for analysis twelve gave indications of contamination. The sanitary authority should not rest till all wells which can by their surroundings be subject to the risk of pollution are closed. During 1884 the number of houses supplied with the public service was 400; and it is to be hoped that similarly rapid progress in this matter may continue.

Barnstaple Urban District. Mr. Henry Jackson has only been in office nine months, but his report for 1884 shows that he has made himself very fully acquainted with all the conditions with which he has to deal as health officer. The death-rate in a population of 12,460 was 17·6 per 1000, which would be reduced still further if allowance were made for extra-urban deaths in the workhouse. Investigation into the origin of cases of infectious diseases has revealed a serious deficiency in the ventilation of the sewers, and the authority have already engaged the services of an engineer to deal with the matter. The need for an infectious hospital has also been shown, and a committee has been formed to look out for a suitable site. As to this, we may point out that the site should be large enough to allow of an ample unoccupied zone between all buildings intended to receive infected persons and things, and the requisite boundary wall. The report throughout shows that a careful officer is, with every prospect of success, bringing under the notice of his authority the conditions as to which sanitary amendment is needed.

Tyne Port District. Mr. Armstrong reports that special vigilance was maintained during 1884 owing to the prevalence of cholera in Southern Europe. A register was kept of all vessels sailing from the East, with the dates of passing different ports, and the time of expected arrival at their destination; satisfactory arrangements were made by the officer of Customs for the early transmission to the sanitary station of information as to cases of sickness, at all hours, respecting arrivals. All vessels reporting "All well" were boarded by the inspector to satisfy himself that this was correct; and when there was any doubt, the advice of the assistant officer of health was at once sought. Vessels from infected ports were all boarded by either the medical officer of health or his assistant. Instructions as to water-supply and precautionary measures were printed and freely distributed. Eight cases were received during the year into the floating hospital namely, four cases of enteric fever, one of typhus, three of febricula, and one which proved to be peritonitis. The existing accommodation is, however, found to be insufficient for the prospective needs of the port, and several alternative schemes for procuring a new hospital are under consideration. One relates to the use of an old man-of-war, another to procuring a disused mission ship, and the third to the building of one or more pavilions on a floating platform. As yet no decision has been arrived at in the matter. The structural defects needing alteration in vessels inspected were 123 in number, and 105 of these had already been remedied. The nuisances which were abated in British and foreign steamers and sailing vessels were 501 in number. All emigrant vessels were visited daily whilst in the port. In short, the general port sanitary work continues to progress, and it must evidently go far to effect a considerable improvement in the sanitary arrangements of vessels and in the quality of the provision made for the crew.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5727 births and 3508 deaths were registered during the week ending the 21th inst. The births were 87 and the deaths 119 below the average weekly numbers during 1884. The annual death-rate in these towns, which had been equal to 24·5, 21·8, and 20·9 per 1000 in the preceding three weeks, further declined last week to 20·5. During the first seven weeks of the current quarter the death-rate in these towns averaged 23·0 per 1000, against 25·0 in the corresponding periods of the nine years 1876-84. The lowest death-rates in these towns last week were 11·8 in Brighton, 15·7 in Birkenhead, and 16·5 in Wolverhampton. The rates in the other towns ranged upwards to 33·3 in Cardiff, 33·8 in Preston, and 37·9 in Sunderland. The deaths referred to the principal zymotic diseases in the twenty-eight towns were 384 last week, against 356 and 398 in the preceding two weeks; they included 117 from whooping-cough, 92 from measles, 45 from scarlet fever, 36 from "fever" (principally enteric), 35 from diarrhœa, 34 from small-pox, and 25 from diphtheria. These zymotic diseases caused the lowest death-rate last week in Nottingham, Brighton, and Bolton, and the highest in Preston, Cardiff, and Sunderland. The highest death-rates from whooping-cough occurred in Salford, Oldham, and Preston; from measles in Newcastle-upon-Tyne, Cardiff, and Sunderland; scarlet fever in Halifax and Sunderland; and "fever" in Newcastle-upon-Tyne and Norwich. The 25 deaths from diphtheria in the twenty-eight towns included 14 in London, 4 in Liverpool, and 2 in Birmingham. Small-pox caused 63 deaths in London and its outer ring of suburban districts, 1 in Liverpool, and 1 in Birmingham. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which had been 1144 and 1223 on the preceding two Saturdays, declined to 1141 at the end of last week; the admissions, which had been 223 and 255 in the previous two weeks, declined to 163 last week, and were fewer than in any week since the end of November last. The Highgate Small-pox Hospital contained 99 patients on Saturday last, 29 cases having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had been 556, 421, and 383

in the preceding three weeks, further declined to 343 last week, and were as many as 220 below the corrected weekly average. The causes of 84, or 2·0 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Leicester, Derby, and Plymouth. The largest proportions of uncertified deaths were registered in Oldham and Salford.

HEALTH OF SCOTCH TOWNS.

The annual death-rate in the eight Scotch towns, which had declined in the preceding three weeks from 30·2 to 26·6 per 1000, further declined to 23·1 in the week ending the 21st inst., but exceeded by 2·6 the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 14·9 and 16·0 in Perth and Leith, to 26·1 in Greenock and 28·3 in Glasgow. The 563 deaths in the eight towns included 31 which were referred to whooping-cough, 21 to measles, 9 to scarlet fever, 8 to diphtheria, 7 to diarrhœa, 6 to "fever" (typhus, enteric, or simple), and not one to small-pox; in all, 81 deaths resulted from these principal zymotic diseases, against 98, 92, and 95 in the preceding three weeks. These 81 deaths were equal to an annual rate of 33 per 1000, which was 1·1 above the mean rate from the same diseases in the twenty-eight English towns. The 31 deaths from whooping-cough exceeded those in the previous week by 2, and included 17 in Glasgow, 4 in Edinburgh, and 4 in Dundee. The 21 deaths from measles showed a decline of 4 from those in the previous week; 15 occurred in Glasgow and 4 in Dundee. Eight of the 9 fatal cases of scarlet fever and 4 of the 8 of diphtheria were returned in Glasgow. The deaths referred to "fever," which had been 6 and 10 in the previous two weeks, declined again to 6 last week, and included 3 in Glasgow and 2 in Edinburgh. The 7 deaths attributed to diarrhœa showed a considerable decline from recent weekly numbers, and were but half the number in the corresponding week of last year. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 214, 189, and 152 in the previous three weeks, further declined to 139 last week; they exceeded, however, by 26 the number returned in the corresponding week of last year. The causes of 67, or nearly 12 per cent., of the deaths in the eight Scotch towns last week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 36·2 and 34·9 per 1000 in the preceding two weeks, further declined to 32·4 in the week ending the 21st inst. During the first seven weeks of the current quarter the death-rate in the city averaged no less than 33·0 per 1000, the mean rate during the same period not exceeding 22·1 in London and 21·3 in Edinburgh. The 206 deaths in Dublin last week showed a further decline of 30 from the numbers returned in the two previous weeks, and included 20 which were referred to the principal zymotic diseases, against 22, 18, and 20 in the previous three weeks. Of these 20 deaths, 11 resulted from measles, 3 from scarlet fever, 3 from diarrhœa, 2 from whooping-cough, 1 from "fever," and not one either from small-pox or diphtheria. These 20 deaths were equal to an annual rate of 3·0 per 1000; the rate from these diseases last week was equal to 2·0 in London and 1·9 in Edinburgh. The fatal cases of measles in Dublin, which had been 3, 5, and 10 in the previous three weeks, further rose to 11 last week; the deaths referred to "fever," however, which had averaged 5 in the preceding six weeks, declined to 1 last week. Four inquest cases and 5 deaths from violence were registered within the city; and 62, or nearly a third, of the deaths were recorded in public institutions. The 28 deaths of infants showed a marked decline from recent weekly numbers, while those of elderly persons exceeded the number in the previous week by 5. The causes of 25, or nearly 13 per cent., of the deaths regisered in the city last week were not certified.

A COMPLIMENTARY farewell dinner was given on Jan. 20th, by the members of the medical profession resident in Calcutta, to Dr. David Boyce Smith, who has recently been appointed to the chair of Medicine in the Army Medical School at Netley.

THE SERVICES.

BRITISH MEDICAL SERVICE.—The following is the list of the successful candidates at the recent Competitive Examination for appointments in this Service:—

	Marks.		Marks.
Hickson, S.	2540	Adams, G. G.	2130
Fletcher, H. J.	2480	Shine, J. M. F.	2120
Lindeman, S. H.	2445	Day, W. B.	2110
Davis, E.	2430	Hamilton, D. R.	2100
Powell, S.	2410	Thompson, R. G.	2080
Jones, F. W. C.	2335	Blackwell, C. T.	2070
Meek, J.	2320	Power, R. I.	2070
Morris, A. E.	2310	Kilkelly, C. R.	2065
Cormack, R.	2300	Bean, W. H.	2020
McMillan, J. F.	2290	Ferguson, N. C.	2010
O'Donel, C.	2275	Wills, S. R.	1980
Carte, W. A.	2270	Hearn, M. L.	1960
Fitzgerald, A. O.	2270	Deeble, S. L.	1950
Elderton, F. D.	2260	Hall, R. H.	1950
Sheldrake, E. N.	2230	Bennett, W. H.	1940
Molesworth, R. E.	2220	Greenway, J. H.	1921
Long, J. W. F.	2215	Hanley, R. G.	1880
Josling, C. L.	2210	Bell, W. H.	1875
Bateson, J. F.	2180	Cree, G.	1850
Swan, W. T.	2180	Philson, S. C.	1850
Bulpin, J.	2175	Nicolls, J. M.	1830
Macleod, R. L. R.	2145	Harris, F. W. H. D.	1800
Curtis, J. H.	2140		

NAVAL MEDICAL DEPARTMENT.—At the competition for commissions in the Medical Service of the Royal Navy, held on Feb. 9th and following days, in the Hall of the University of London, Burlington-gardens, the undermentioned gentlemen were the successful candidates:—

	Marks.		Marks.
South, H. E.	2090	Minter, E. D.	1720
Page, A. M.	2010	Alsop, C.	1710
Cropley, A.	1930	Eede, E. T.	1695
Jenkins, J.	1910	Chamberlain, C. B. d'E.	1690

INDIAN MEDICAL SERVICE.—At the Competitive Examination held at Burlington House on Feb. 9th the following gentlemen were successful:—

	Marks.		Marks.
Campbell, E. K.	2590	Carroll, E. R. W. C.	2220
Drury, F. J.	2495	Dyson, H. J.	2160
Rogers, F. A.	2230		

Eighteen candidates competed for five appointments. All were reported qualified.

THE EGYPTIAN EXPEDITION.

So many of the officers of the Army Medical Staff have been ordered abroad that civilian surgeons have been temporarily appointed to the charge of troops in the Chatham garrison. The deficiencies in the number of medical officers in Woolwich also are being supplied by the temporary employment of three retired medical officers and five qualified but unsuccessful candidates for Netley.

On the 25th inst. the Prince and Princess of Wales paid a visit to the *Ganges*, which has been chartered by the Admiralty to act as a hospital ship at Suakim, and to which we have referred in another column.

On the 24th inst. the hospital and bearer companies of the medical staff, amounting in all to about 300, arrived by train at Woolwich, from Aldershot, in charge of Surgeon-Major Evatt, and embarked on board the steamship *Calabria* for Suakim. The final inspection of the ship, which sailed on the 25th inst., was made by Colonel Julian Hall and Surgeon-Major Clarke, assisted by Surgeon-Major Riordan, who went out in charge of the troops.

Surgeon Birrell, of the Army Medical Staff, has been placed on board the *Osprey* in charge of the first portion of the navvies who are to be employed in constructing the Suakim-Berber railway.

Thirty medical officers, now undergoing drill instruction at Aldershot, are under orders for foreign service. Fifteen are to proceed direct to Suakim, and the remainder are for service at Gibraltar, Malta, and in India, to replace others ordered from those places to the Soudan.

Surgeon Keefe has gone out in medical charge of the *Conway Castle*, on which troops have embarked for Gibraltar.

ARMY MEDICAL STAFF.—Surgeon Campbell Louis Young has been placed temporarily on the half-pay list, in consequence of ill-health. The undermentioned surgeons on probation to be Surgeons: James Rocheid Forrest; Michael William Russell; William Raoul de Morinni;

Benjamin Frazier Zimmermann; Arthur Frank Stace; Alexander Stables, M.B.; John Frederick Edward McCraith; Edward Arnold Cloete Smith; William Maxwell Hewson, M.B.; Grenville Edwin Moffet, M.B.; Henry Aylmer Haines, M.D.; John Drew Moir, M.B.; Richard Crofts; George Magill Dobson, M.B.; George Ernest Hale; Cecil Willoughby Johnson, M.B.; William Ebenezer Berryman; Alfred Thomas Irvine Lilly; Robert Caldwell; Charles Cooper Reilly; Sidney Edward Duncan; James Maher; Allan Perry; Samuel N. Cardozo; Arthur De Courcy Scanlan; Hartwell Woodhouse James; Robert Trevor; Henry Daniel James; William Turner; Brooke Owen William Norfor, M.B.

INDIA OFFICE.—Surgeon F. J. Tuohy, M.D., of the Indian Medical Service (Bengal), has been transferred to the half-pay list. Dr. Tuohy served in the Afghan war in 1878-79, and took part in the advance on Candahar and Tehelat-i-Ghilzi under Sir Donald Stewart.

ADMIRALTY.—The following appointments have been made:—Surgeons Henry E. South, Robert T. Bowie, John N. Corbett, M.D., Charles B. d'E. Chamberlain, Eli T. Eede, Clement Alsop, Ernest D. Minster, Horace Elliott, M.D., Sidney H. Youel, John Jenkins, Alfred Cropley, and Alfred M. Page, additional, to the *Duke of Wellington;* Surgeons George A. Dreaper, William H. O'Meara, William W. Jacobs, and Alexander F. Harper, additional, to the *Royal Adelaide:* Surgeon Edward R. D. Fasken, additional, to the *Impregnable;* Surgeon James C. F. Whicher, additional, to the *Cambridge;* Surgeon Alexander G. Andrew, additional, to the *Excellent;* Surgeon Arthur S. Nance, additional, to the *Vernon.*

MILITIA MEDICAL STAFF.—Surgeon-Major John Kilner, 3rd Battalion, the Suffolk Regiment, resigns his commission, also is permitted to retain his rank and to wear the prescribed uniform on his retirement.

RIFLE VOLUNTEERS.—8th (S.W.) Middlesex: Honorary Assistant-Surgeon John Prince to be Surgeon.

WILLS OF MEDICAL MEN.

THE will of Richard Seymour, M.D., late of 3, Palace-square, Upper Norwood, who died on Nov. 28th last, has been proved by Mr. John Wight, Mr. Hobart Seymour, the nephew, and Mr. William Alfred Impey, the executors, the value of the personal estate exceeding £8900. The testator bequeaths his furniture and effects to his wife, and legacies to his executors and nephews. The residue of his property he leaves upon trust to pay the income to his wife for life; at her death he gives the fee simple of his houses at Dublin, and his share in some houses at Limerick, to his said nephew; considerable pecuniary legacies to other relatives, and the ultimate residue to Robert Seymour and Edward Otto Impey.

The will and codicil of Daniel John Duigan, C.B., M.D., Deputy Inspector-General of Hospitals and Fleets, late of 29, Edith-road, West Kensington, who died on Dec. 2nd last, were proved on the 24th ult., by Mrs. Mary Anne Duigan, the widow, and Mr. Martin Cormac, the acting executors, the value of the personal estate amounting to over £6900. The testator leaves his residence, with the furniture and effects, to his wife for life, and then to his three children as she shall appoint; £2500 each to his son Alfred Leopold and his daughter Lucie Foley; £1000 to his son Valentine Richard; an annuity of £52 to Bridget MacCormac; and the residue of his property to his wife absolutely.

The will of Valentine Hutchinson, M.D., late of the Elms, Bishop Auckland, Durham, who died on Dec. 16th last., was proved on the 7th ult., by Mr. Robert Shum Mansel, J.P., one of the executors, the value of the personal estate amounting to over £2000. The testator leaves legacies to his executors and others; and the residue of his real and personal estate to be divided equally between all his children.

The will of Llewellyn Morgan Thomas, M.D., late of 15, Weymouth-street, Portland-place, who died on Nov. 26th last, was proved on the 21st ult., by Miss Jane Wyman, the sole executrix, to whom he gives, bequeaths, and devises the whole of his real and personal estate.

The will and three codicils of John William Moore, M.D., late of Southsea, in the county of Southampton, who died on July 9th last, were proved on the 17th ult., by Mrs. Catherine Jemima Moore, the widow, the value of the personal estate amounting to over £2000. The testator, after making some bequests, leaves the residue of his real and personal estate upon trust for his wife for life, and then for his three daughters, Mrs. Bowden-Smith, Mrs. Meldrum, and Miss Moore.

The will of Frederick Henry Horatio Akbar Mahomed, M.D., late of 24, Manchester-square, who died on Nov. 22nd last, were proved on the 24th ult., by Mrs. Ada Mahomed, the sole executrix, to whom he gives, devises, and bequeaths all his estate and effects absolutely. The value of the personal estate exceeds £1900.

The following legacies have recently been left to hospitals and other medical institutions:—Sir George St. Patrick Lawrence, K.C.S.I., C.B., late of 20, Kensington-park-gardens, £100 to the Medical Branch of the Indian Female Normal School and Instruction Society; the Most Hon. William Henry Hugh, Marquis of Cholmondeley, of Cholmondeley Castle, Cheshire, of Houghton Hall, Norfolk, and of 1, Hyde-park-street, £500 to the Hospital for Women, Soho-square; Mr. Dennis Herbert, late of the Priory, Huntingdon, £200 to the Huntingdonshire County Hospital, and £100 to the Hunstanton Convalescent Hospital; Mr. J. Gorman, £400 to the Mater Misericordiæ Hospital, £500 to St. Michael's Hospital, £1000 to St. Mary's Asylum for the Blind, and £500 to the Hospital for Incurables; Mr. J. Winter, £50 to the Adelaide Hospital, Dublin; Major-General Pope, £3000 for a medical dispensary at Helmsdale, and £2000 to Inverness Infirmary, for the express benefit of Kildonan patients.

Correspondence.

"Audi alteram partem."

TYPHUS IN CAMBERWELL.

To the Editor of THE LANCET.

SIR,—In reference to the recent outbreaks of typhus in Camberwell, on which you comment in your last issue, I think I have a right to claim that the local authorities have not been neglectful of their duties.

As you point out, we have had two outbreaks. The first was limited to one house in Verney-flats, a tenement house occupied mainly by Irish labourers, and situated on the confines of the parish, close to Rotherhithe. In this house, between Nov. 10th and Dec. 15th, seven cases occurred in two families, and two died. That the disease was typhus was ascertained at the beginning of the outbreak, and every case as it occurred was at once removed to hospital. How the disease became imported we could not ascertain. But no cases, so far as we know, have been met with in that locality since. The more recent outbreak has occurred half a mile away from the other. On Jan. 28th the inspector's attention was called to 17, Down-street, in which a man and his wife had recovered from a mild attack of fever, the nature of which was not specified. As it turns out, this was probably typhus; but we had no proof of this. Then, between Feb. 9th and 11th, three children were removed from 3, Bexley-place, and, three from 5, Down-street, with what was stated to be enteric fever. These streets are close together; and, as soon as I was informed of what had occurred, it struck me that the behaviour of the disease was much more like that of typhus than that of enteric fever; and I made inquiries at the district hospitals and found that my suspicions were correct. This was on the 12th. Between the 9th and the 22nd there have been twenty-three cases in these two streets and their immediate neighbourhood, of which fifteen have occurred in two houses. Of these, one suffering from haemoptysis was taken by his friends to St. Thomas's; but all the rest were removed at once to the district hospitals. It is curious that all the persons attacked, except four or five, have been children. And doubtless it is largely owing to this circumstance that no deaths have occurred up to the present time. The same fact, and the early removal of the cases to hospital, explain also how it was that the medical men in attendance failed at first to recognise the nature of the disease. This latter outbreak, like the former one, has occurred in an Irish colony. I presume that the two are related; but I am unable to trace the connexion.

I am, Sir, yours faithfully,

Old Burlington-street, W., Feb. 25th, 1885. J. S. BRISTOWE.

THE CLINICAL SOCIETY: THE PRESIDENT'S ADDRESS.

To the Editor of THE LANCET.

SIR,—I find that the President of the Clinical Society, in his inaugural address, has borrowed certain expressions from a private letter of mine, and reproduced them as an indication of a too general confusion of thought with reference to the relationship of inflammation to the healing of wounds. Without referring at length to the circumstances which led me to correspond privately with Mr. Thomas Bryant on this subject, I will content myself with a brief statement of the points at issue.

As a teacher of surgical pathology I have deemed it in accord with ascertained facts to regard the healing of wounds as essentially an inflammatory process, and to recognise that inflammation may have a formative as well as a destructive termination. That there may be no uncertainty here I would go further, and say that the formative is even more typical of an inflammatory process than is the destructive termination. In my lectures, however, I never fail to point out, as clearly as possible, that this view is one which is necessarily dependent on a corresponding conception of the inflammatory process. Mr. Bryant, on the other hand, considers that inflammation, or anything like inflammation, is fatal to the healing of wounds; that repair and inflammation are, in short, incompatible; and that repair beginning "by what is called granulation," and ending in cicatrisation, is a physiological and not a pathological process, which is only possible in the absence of inflammation. It is manifest that these views are only tenable with a correspondingly limited comprehension of what is implied by inflammation. Mr. Bryant knows quite well that the real cause of the confusion he deplores is entirely traceable to different views as to what "inflammation" really implies; and by ignoring this he raises a false issue, which calls for a very considerable exercise of that generosity for which he asks. Mr. Bryant pleads for clear views and precise thought. In this I most heartily join, but I would point out that "clearness" is only a part, and not the most important part, of what is essential in our views. Not only must a view be clear, it must also be adequate, or, in other words, it must accord with facts. Lest this statement should present itself to Mr. Bryant as a "mixed expression"—which merely conveys a "cloud of words," whilst it "covers uncertain views,"—I will endeavour to illustrate what I conceive to be the distinction between a view which is clear only and one which is both clear and adequate at the same time. Under the circumstances, Mr. Bryant can hardly complain if I borrow my illustrations from his own writings. In the fourth edition of his work on Surgery is the following statement:—"Acetic acid dissolves the nucleus of a leucocyte"; and this is made a distinctive feature between white blood-corpuscles and pus-cells. The view thus expressed is clear enough, painfully clear, but it is not adequate, for it is not in accordance with facts. Again, the view that granulation and cicatrisation are physiological and not pathological processes is another example of a view which is clear but not adequate. In my opinion Mr. Bryant's views on the relationship existing between inflammation and the healing of wounds are throughout equally clear and equally inadequate.

To my mind inflammation is a continuous process, from the first deviation from health up to any of its terminations, whatever the termination may be. The practical surgeon finds, however, no difficulty in drawing a sharp line of demarcation between its destructive and formative terminations, nor even the most instructed pathologist finds himself able to make a trenchant distinction between that kind of nutrition which constitutes health and that of the first stage of inflammation; or between the minor degrees of inflammation which terminate in repair and the major degrees which terminate in destruction of tissue. Inflammation being regarded as a continuous process, the minor and major degrees graduate insensibly into one another.

To illustrate this from another source. It is an easy matter for even the uninstructed to hold fairly clear ideas of the distinctions between a horse and an oak tree, whilst the most learned find it impossible to draw a sharp line of demarcation between the lowest forms of animal and vegetable life. By ignoring inconvenient facts it is possible to draw sharp distinctions in cases where they do not actually exist, but though by so doing clear views may be formulated, they cannot be adequate, and must inevitably lead to that confusion which it is intended to avoid.

In conclusion, I cannot but regard Mr. Bryant's views as fatal to true teaching, and however ready I should be to defer to his judgment on a purely practical question in surgery, I feel it incumbent upon me to protest strongly against the idea that his position as an examiner entitles him to dictate, either publicly or privately, to teachers of pathology what doctrines they shall or shall not teach.

I am, Sir, yours truly,

A. H. YOUNG,
Lecturer on Surgical Pathology, Owens College, Manchester.

Feb. 24th, 1885.

THE MICRO-ORGANISMS OF YELLOW FEVER.

To the Editor of THE LANCET.

SIR,—With reference to the reissue of Dr. Domingos Freire's communication to you on the subject of the report on certain experiments on the propagation of yellow fever made by us for the Colonial Office, we hope you will kindly allow us, in the first place, to state that we undertook this inquiry not to show that Dr. Freire's theory was ill-founded, but, on the contrary, with the hope of being able to confirm his results. As the inquiry proceeded we found nothing to enable us to do so, and then, on comparison of his results with ours, and on careful perusal of his publication, "Etudes Expérimentales sur la Contagion de la Fièvre Jaune," we came to the conclusion that the Doctor had perhaps misread appearances, and, carried away by enthusiasm, had written what, in the cold light of discussion, could not be, at least fully, sustained. In the second place, we would ask your permission to reply to the strictures of Dr. Freire on our experiments as given in your summary of his letter as it appears in your issue of Sept. 27th, 1884.

1. It is objected that we performed our experiments with cultures of grave mould, &c., whereas Dr. Freire used the mould itself diluted with water. We also used a simple solution of mould; but, not getting any result, we made no mention of the matter in the report. We beg, however, to point out that on page 43 of the above-mentioned pamphlet Dr. Freire states: "A cet effet, nous avons inoculé premièrement *la même culture* qui avait servi dans l'expérience précédente à un cochon d'Inde," where he refers to a culture of the supposed "cryptococcus xanthogenicus" in gelatine, and goes on to say: "Le cinquième jour l'animal était mort. ..... L'examen microscopique montra une quantité extraordinaire des microbes caractéristiques," &c. Here surely is a "culture" that produces fatal results. But again, as to the diminished virulence of cultures by transplantation, we did not use a single transplantation; we injected cultures of the moulds direct. Dr. Freire seems to forget that we do not complain of the absence of virulence in our cultures; they proved extremely and very rapidly fatal. What we noted and wish now again to draw attention to, is the fact that a little pure soup exposed to the open air outside the laboratory for fifteen minutes and then placed in the incubator at a temperature of 98·6° F. for twenty hours, under the same conditions as the other materials as to plugging, &c., proved equally fatal with a culture of grave mould, common field mould, or that made direct from a dead body (yellow fever case). The symptoms during the illness of the animals and the post-mortem appearances being in every case very similar, and not at all like those of yellow fever in the human body, it will be seen that we had not the slightest grounds for believing that any of the animals died of yellow fever.

2. It is next objected that we used earth from limed graves. So we did, but only in two out of some twenty cases, and we have plainly stated the difference of our results in these cases.

3. Next as to the statement that "it is likely the organisms would have perished"—that is, during the additional year only that elapsed before our experiments were made. Surely the spores of these organisms would not have perished in that time, and the use of a plain deal shell coffin could not be credited with the power to prevent the spread of contagion from a putrefying yellow fever corpse to the surrounding soil.

4. Dr. Freire points out that we got fatal results when experimenting with solutions of dead bodies, and claims that as in favour of his theory; but surely he must have

overlooked the fact that one of the bodies thus experimented with was not a yellow fever corpse at all, and yet the symptoms produced by the injection of a little juice from this were exactly the same as those produced by the solution of a yellow fever body, the only difference being that the body which had not died of yellow fever, perhaps as it was but six months old, killed somewhat quicker than the two-year-old yellow fever body!

5. Dr Freire asks, "How was it, supposing the disease to have been septicæmia, that no bacteria were discovered in the blood?" Why, if the Doctor's theory be true, should not the question be, "How is it that, if the disease were yellow fever, no bacteria were discovered in the blood?" But surely Dr Freire is not ignorant that there are several forms of fatal septicæmia, in which, if the body be examined immediately after death, no trace of bacterial life will be found.

6. The Doctor then goes on to give accurate descriptions of the condition of the viscera of guinea-pigs after death by what he considers yellow fever; but surely these are not the appearances found in the human body after death from that disease. "Grey colour of brain," "swollen and blackish liver," "full bladder," "stomach full of food," &c., are not what one would expect to find in corpses dead of yellow fever. Albumen in the urine is certainly a constant symptom of fatal yellow fever, but it does not follow that albuminuria is yellow fever. On the whole, we are inclined to think that when Dr. Freire wrote his last letter to you he had not had our report translated correctly; at least, that seems the easiest way to account for some evident misunderstandings.

It is with regret that we find ourselves obliged to consider that Dr. Freire's experiments are still in need of verification, and this regret is deepened when we remember the difficulties that are thrown in the way of any attempt of ours to help to elucidate this most interesting question. It will scarcely be believed, but it is nevertheless a fact, that during the absence in England of the Governor-in-Chief, at whose request our inquiry was instituted, the officer temporarily administering the Government, supported by the opinion of some gentlemen of the Army Medical Department and others, which he requested, formally prohibited any further prosecution of our work on some such grounds as that such inquiry was valueless and dangerous to the public health, the work we were at the time engaged on being an examination of the toxic properties of various media cultivated at a high temperature and impregnated by exposure to the open air or by garden mould; and, further, an inquiry as to how far fresh lime might be depended on as destructive of bacterial germs in earth, no grave having been touched by us for about a twelvemonth. Obstacles have been put in our way also by other means, and when it is remembered that we undertook the inquiry only when everyone else in the West Indies had declined to have anything to do with it, and at the request of the authorities it will, we think, be admitted that we have some ground for complaint.

Before closing we would beg to remark that a healthy guinea-pig that had been inoculated with a weakened culture, and seemed proof against fresh inoculation afterwards, as mentioned in our report, succumbed some months ago to an inoculation by soup impregnated by the open air. We should wish, on our part, to ask Dr. Freire, with reference to his recent statement to the Académie des Sciences, as to his pigs dying in numbers of yellow fever on exposure to the impregnated air of his laboratory, how is it that such animals do not die *outside* his laboratory during the prevalence of an epidemic of yellow fever?

We are, Sir, your most obedient servants,
J. H. SUTTON MOXLEY, B.A., &c., &c.
J. B. HARRISON, B.A., Island Professor of Chemistry.

Barbadoes, Jan. 28th, 1885.

COCAINE IN CHRONIC CYSTITIS AND IRRITABLE BLADDER.

To the Editor of THE LANCET.

SIR,—Mr. Bellamy's note on the above in THE LANCET of the 14th inst. determines me to send you a confirmatory observation, though used in one case only.

I have been treating a gentleman, over sixty-eight years of age, for chronic cystitis, bladder sacculated, dependent on prostatic disease; latterly the symptoms have been much aggravated, micturition every few minutes, with intense pain at the neck of the bladder, thick muco-purulent discharge when the bladder is washed out (twice daily with boroglyceride), and diarrhœa. Almost every remedy has been used—by mouth, injections, suppositories—all fruitlessly. A fortnight ago I injected into the bladder one-third of a grain of hydrochlorate of cocaine in four or five ounces of tepid water, and retained for ten minutes. Next morning I was pleased to find he had been perfectly free from pain, and the diarrhœa soon ceased. I have since used it four times, the freedom from pain lasting from twenty-four to thirty hours, but the frequency of micturition and quantity of sediment remain unaltered. The last few days he has complained of similar pain along the urethra, and I intend using the gelatine bougies medicated with cocaine as suggested by Mr. Bellamy. I am, Sir, yours, &c.,

Seaforth, Liverpool, Feb. 1885. F. F. GERMAN.

THE TREATMENT OF GONORRHŒA, ETC., BY A NEW DRUG.

To the Editor of THE LANCET.

SIR,—I wish to draw the notice of the profession to the therapeutic action of the Jacaranda lancifoliata. This plant is indigenous to Columbia, South America, and was brought over to this country by an acquaintance, who, whilst travelling in the above State, found that the drug was used by the natives as a remedy in venereal diseases. Some of it was placed in the hands of my partner, Dr. Murray Smith, and myself to see what effect it had; and we were very much gratified by its influence in gonorrhœa, acute and chronic, and in vesical affections attended with purulent and muco-purulent urine. The drug acts specially on the genito-urinary mucous membrane, and appears to have no deleterious effect in any way; whilst it is taken without nausea, contrasting very favourably with most drugs given internally for these affections. As a remedy for gonorrhœa, I believe it will, when known, take the place of all other drugs used internally for this disease. In my hands, it has proved most efficacious in diminishing pain and stopping discharge in acute cases; and in cases of gleet I have found it most valuable, having succeeded in effecting a speedy cure by its use in several cases which had resisted previous treatment, both local and general. A liquid extract is made from the leaf, and may be given in doses of twenty minims or half a drachm three or four times daily. The introducer of the drug is prepared to send a small supply free of charge, prior to its being placed in the market, to any medical man who will try it and report his opinion to him. It is to be obtained of Mr. E. H. Lawton, 38, Trinity-square, Tower-hill, E.C. I am, Sir, yours truly,

Romford, Feb. 10th, 1885. ALFRED WRIGHT.

REVACCINATION.

To the Editor of THE LANCET.

SIR,—I herewith send you a copy of a memorial praying for further encouragement and facilities for the revaccination of adults, which I have this day forwarded to the President of the Local Government Board.

I am, Sir, yours truly,
FRANCIS VACHER, Hon. Sec.

Office of North-Western Association of Medical Officers of Health, Feb. 25th, 1885.

MEMORIAL PRAYING FOR FURTHER ENCOURAGEMENT AND FACILITIES FOR THE REVACCINATION OF ADULTS.

To the Right Hon. Charles Wentworth Dilke, Bart., M.P., President of the Local Government Board.

The memorial of the North-Western Association of Medical Officers of Health respectfully sheweth,—

1. That your memorialists are a body of medical officers of health practising in the counties of Lancaster, Chester, and Derby, and the West Riding of the county of York.

2. That there is still a considerable annual mortality from small pox in some of the districts served by your memorialists and in many districts throughout the kingdom.

3. That efficient vaccination of infants and revaccination of adults would prevent this mortality.

4. That while fairly satisfactory regulations obtain for securing the efficient vaccination of infants, no adequate steps have yet been taken to secure the revaccination of adults.

5. That the usefulness and expediency of the revaccination of adults is already recognised by many Government departments, inasmuch as military and naval recruits, post-office employés, &c., are required to submit to the operation.

6. That the principle thus admitted is capable of legitimate extension, by making proof of vaccination a qualification for all Government employment, and by making revaccination compulsory on all adults residing in premises which may become infected with the contagion of small-pox, and on all adult applicants for poor-law relief.

7. That the fee at present allowed for successful revaccination is not sufficient to excite any interest in the performance of the duty on the part of the public vaccinator, and does not fairly repay him for his expenditure of time and trouble.

8. That efficient revaccination would be promoted and encouraged by furnishing to all legally qualified medical practitioners, on request, an ample supply of calf and humanised lymph.

9. That your memorialists trust your honourable Board will consider the slight encouragement at present given for the promotion of revaccination and the propositions respectfully submitted by your memorialists, and will take such steps as your honourable Board may deem desirable for increasing and furthering the practice of revaccination.

And your memorialists will ever pray.

(signed on behalf of the North-Western Association of Medical Officers of Health),

EDWIN RAYNER, M.D., F.R.C.S., President,
FRANCIS VACHER, Hon. Sec.

16 King-street, Manchester, Feb. 23rd, 1885.

EXAMINATION OF DRINKING WATER.

To the Editor of THE LANCET.

SIR,—I should be glad to have an opinion of the value of Horsley's pyrogallic acid test in the determination of the presence of nitrates and nitrites in water. Wanklyn's method is no doubt the best, but takes too much money and time in rural districts, where every other house has its own well, and sanitary pay is small. If there are any grave objections to Horsley's process, I should be thankful to be informed where I can get a description of any other simple process of water examination which will supplement the silver test and the microscope.

I am, Sir, your obedient servant,

Feb. 21st, 1885. RURAL HEALTH OFFICER.

*** We have never used the method above referred to, nor doubt its trustworthiness. Of satisfactory processes, the simplest is the brucine process, described in *The Analyst*, vol. vi. It must be remembered that the presence of nitrates and chlorine is a very fallacious guide. The determination of albuminoid ammonia cannot be dispensed with unless the much more difficult combustion process is used. It is a good plan to keep the water in a warm place, loosely covered, for several days. If bacteria and bacilli increase readily, there must be some suitable pabulum for them in the water.—ED. L.

LIVERPOOL.

(*From our own Correspondent.*)

THE LIVERPOOL MEDICAL INSTITUTION.

THE members of the profession in this city are fortunate in the possession of their medical institution. Formed in 1857 by the amalgamation of the Medical Society and the Medical Library, it now numbers 185 members, 24 associates, and 4 honorary members. It has its own buildings, erected in 1873 on a central and very convenient site granted by the Corporation, who also gave £1000 towards the building, the remainder being provided by the donations of members and their friends. The meetings are held on alternate Tuesdays during the winter months, and are well attended. In a large a city as this, with its numerous hospitals and dispensaries, furnishes an unlimited amount of material for interesting papers, cases, and discussions, while the numerous pathological specimens shown by members form an additional feature of interest. The microscopical section of the institution, which was formed some years ago, meets on alternate Fridays, and has proved a most valuable adjunct to it. At the annual meeting held last month it was resolved to admit at a reduced subscription members of the profession residing beyond a radius of ten miles. It is believed that this will enhance greatly the benefits of the institution, and its members present and prospective. The library contains nine thousand volumes.

HYDROPHOBIA.

Recently there have been several cases of persons having been bitten by dogs, apparently mad, in the streets. One case, that of a boy, terminated fatally with all the symptoms of hydrophobia. There would in all probability have been more fatal cases had it not been for the bravery of a police constable, who pursued and killed the savage animal, and was warmly commended for his courageous conduct by the county coroner and jury at the inquest. In the course of a year several cases of police officers bitten by dogs came under the notice of the police surgeons. The danger is a very real one, and it is very important that means should be taken to prevent it.

DEATHS OF CHILDREN FROM OVERLAYING.

This city has an unenviable notoriety for the large number of children who are annually suffocated while in bed with their parents, one or both of whom have gone to sleep in a more or less drunken condition. The majority of these cases occur on Saturday and Sunday nights, days which are still devoted to drinking by too many of the lower orders, notwithstanding the advance of temperance among all classes. Many efforts have been made to prevent this wholesale slaughter of children, but without avail. Fifteen years ago a jury, acting under the guidance of the borough coroner (Mr. Clarke Aspinall), returned a verdict of manslaughter against the parents of a child who was found dead in bed with them. The case was a very aggravated one, it being proved that the parents, who were both intoxicated, went to bed in the afternoon, and, though remonstrated with, insisted upon having the child with them. They were committed for trial upon the coroner's warrant, but the grand jury threw out the bill. More recently, in a case little if any less shocking, the parents were committed for trial by both the coroner and the stipendiary magistrate. A true bill was found, but the case ended in an acquittal. It is clearly impossible to draw the line between crime and accident in these cases in the present state of the law.

THE LOCK HOSPITAL.

The clinical lectures delivered by Dr. Bernard during the first part of the winter session were resumed by Mr. F. W. Lowndes after the Christmas recess. They have now been replaced by clinical demonstrations in the male wards, which are given every Saturday at 12.15 P.M., and are greatly appreciated by the students. The wards have been very full lately, and both surgeons have excellent opportunities of pointing out to the clinical class all the various appearances in primary and secondary syphilis. Cases of tertiary syphilis are much more rare than they were in this hospital twenty years ago, when it was not uncommon to see several cases at a time in a very severe form, both in the male and female wards. A case of sloughing ulcer, involving the whole of the prepuce, was recently admitted under Dr. Bernard, and has done remarkably well. Iodoform in fine powder was found very useful in this as in previous cases, partly to promote healing and also as a deodoriser.

THE EYE AND EAR INFIRMARY.

The retirement of Mr. Stradford Walker from the acting to the consulting staff, and the resignation of Mr. Stone, the senior assistant surgeon, have made great changes in the surgical staff of this important charity. Mr. Edgar Browne, well and favourably known as a successful oculist, as well as for his work on the ophthalmoscope, becomes senior surgeon. His colleagues are Mr. Richard Williams, who has for some years done very useful work, first as assistant-surgeon, and subsequently as surgeon; and Mr. Charles George Lee, who has for seven years worked as assistant-surgeon. Mr. Shears, the late house-surgeon, now becomes senior assistant-surgeon, and the committee are inviting candidates to apply for the vacant office of assistant-surgeon. It is much to be regretted that the infirmary has lost the services of Mr. Stone, who has served it faithfully for some years as assistant-surgeon. The ophthalmoscopic demonstrations,

which were commenced at the hospital by Mr. Browne some time ago, have been resumed, and are well attended by local practitioners. Mr. Liptrot succeeded Mr. Shears as house-surgeon.

THE DISPENSARIES.

Some idea of the enormous amount of medical relief afforded by the North, South, and East Dispensaries of this city may be formed from the following details given at the annual meeting held on the 24th inst.: Total number of patients treated during the year 1884, 69,754; total attendances, 151,807. This work was done at a cost of £4506.

Liverpool, Feb. 25th.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

SUNDERLAND HOSPITAL SUNDAY.

THE twenty-first annual collection on behalf of the Sunderland hospitals was taken on the 15th inst. The past year witnessed the largest number of in-patients the infirmary has ever received, 1482 having been treated in the wards, and the number of out-patients was 1665. The collections last year amounted to £729, and this was the largest amount ever contributed on Hospital Sunday. I regret to hear that the present commercial distress in the North has seriously affected the income of the infirmary, which is stated to be £4000 in debt. I trust this is exceptional, as the Sunderland Infirmary is well deserving of public support, being conducted on the free system, and thus a boon to the suffering poor of the borough.

DURHAM COUNTY HOSPITAL.

The annual meeting has been held of the Durham County Hospital, and the report shows that 1566 cases were treated during the year, being an increase of 285 over the number treated last year. The Durham Hospital Sunday Collections are considerably less than last year; but, on the other hand, it is gratifying to read in the report that the Hospital Saturday Collection shows a very marked increase. The excess of expenditure for the year is to be accounted for by the increase of patients, as well as the unfortunate illness of several members of the hospital staff, involving considerable expense in the way of providing substitutes, the complete rectification of the drainage of the hospital, and the preparation for building a new wing, towards which the munificent donation of £2000 has been presented by John Eden, Esq., Beamish-park.

GATESHEAD DISPENSARY.

At the annual meeting of the Gateshead Dispensary, Dr. Robert Purdie presented the medical report, which shows that the number of patients treated by letter during the year was 2815, as compared with 2873 in the previous year; the number of casuals was 10,003, as compared with 14,966 in the previous year. The diminution in the work done was accounted for by the healthier state of the town during the past twelve months, which was most satisfactory, considering the depression in trade and the distress which had existed. The report of the committee refers to the want of hospital accommodation at Gateshead. Indeed, this want is felt and admitted on all sides. At the same time, they say that the matter should be left to the town at large to be dealt with; but it is to be feared that if it is left to "the town at large," there it will rest. It is a long time now since Dr. Newcombe and others drew attention to this want, and yet here is a prosperous town of 70,000 inhabitants without even a cottage hospital. The sick poor of Gateshead flock to the Newcastle Infirmary and to the special hospitals of our city. Dr. Newcombe, at the same meeting, when returning thanks for the complimentary vote passed to the honorary medical staff, also animadverted very strongly on the practice of making even a small charge to the casuals at a time like the present, when so many were out of employment. Speaking from his own knowledge, he knew of cases where poor persons were prevented from seeking aid at the dispensary from the existence of this casual charge, but he also objected to it as having a bad tendency in the way of giving an idea of "cheap physic" to the working classes.

Newcastle-on-Tyne, Feb. 17th.

BELFAST.

(From our own Correspondent.)

THE THOMPSON MEMORIAL HOME, LISBURN.

THIS very handsome building is now completed and open for the reception of patients. It stands on an elevated piece of ground, about half a mile from Lisburn and eight miles from Belfast. Including the building site, the total area of the surrounding grounds is nine acres. The expenditure on the whole range of buildings, together with the fitting and furnishing of the patients' downstair- and day-rooms, as well as the apartments for the lady superintendent, the servants, and nurses, will be close on £25,000. In addition to this large sum, £35,000 has been placed by the founders in the hands of trustees, the annual interest of which will go to the support of the institution. I understand that, according to the trust deed, the home is to be devoted to the reception and support, as well as to the medical and surgical treatment, of respectable poor persons suffering from incurable diseases. Applicants for admission must be able to show that they have resided for five years in some one or more of the counties of Antrim, Armagh, Derry, Down, Monaghan, and Tyrone. The Thompson Memorial Home has been founded by the widow of the famous medical practitioner, the late Dr. Thompson of Lisburn, his daughter, Mrs. Bruce, and his son-in-law, Mr. James Bruce, D.L., of Thorndale House, Belfast. Mr. Ferguson, son of Dr. Ferguson of Belfast, is the architect; and Dr. H. George of Lisburn has been appointed medical attendant. There can be no doubt that this home, to the building and endowing of which one family has given the large sum of £60,000, will be an immense boon to many incurables in Ulster.

THE BELFAST ROYAL HOSPITAL.

It is very gratifying to find by the report read at the quarterly meeting of the Board of Management on Monday that the financial position of this excellent charity has greatly improved. At the last quarterly meeting the hospital was over £2000 in debt. Now all this is paid, and a substantial balance is in the hands of the treasurer. The bazaar yielded the net sum of £2839 1s. 10d., besides £355 contributed specially to create life governors, thus benefiting the hospital to the extent of £3294 1s. 10d. By these means the hospital is freed of debt. The report states that in continuation of the good work going on of putting the wards of the hospital into most efficient condition, the Sinclair Ward has been completed by the members of the Sinclair family. Two small wards for the use of the extern patients connected with the gynæcological department have been thoroughly fitted up and furnished by Mrs. Dunville, and Mr. Dunville is proceeding with the work of completing the remaining wards in the body of the hospital.

THE QUEEN'S COLLEGES COMMISSION.

The Commissioners have just handed in their report, and, as I anticipated in a previous letter, they are divided. The two Roman Catholic Commissioners (Rev. Dr. Molloy and Mr. Carton, Q.C.) report on the low arts standards in Cork and Galway contrasted with the Intermediate and Royal University examinations, the inadequate medical education in Galway, the absence of Roman Catholic students in both colleges owing to religious considerations, and the justice of Roman Catholics obtaining a share of State endowment for collegiate education. The majority of the Commissioners (Dr. J. J. Stoney, secretary to the late Queen's University, Dr. Jack, Glasgow University, and Deputy-Surgeon-General Marston) are satisfied with the arts standard, praise the arts professors, and suggest increased equipment. All the Commissioners agree as to the efficiency of Queen's College, Belfast. Among the recommendations of the majority of the Commissioners are:—"That funds should be provided for the payment of a limited number of assistants to professors who require them for the more efficient teaching of their classes. That provision should be made for the erection of a suitable laboratory for practical chemistry, and for the improvement of the chemical buildings in Belfast. That the medical professors who are not prohibited from private practice be entitled to retiring pension. That the chairs of Anatomy and Physiology and Histology in Queen's College, Belfast, and in Queen's College, Cork, be separated; that in view of this separation compensation be given to the present occupants, and sufficient salaries provided for these chairs."

Belfast, Feb. 25th.

PARIS.

(From our Paris Correspondent.)

COLLECTIVE INVESTIGATION.

At a recent meeting of the Société Médicale des Hôpitaux it was decided that a Collective Investigation on the Contagiousness of Tuberculosis should be instituted, and that printed instructions should be forwarded to all the medical *men* practising on French territory. Although this decision was almost unanimously adopted by the members present, yet there are some misgivings as to the success of the undertaking after what has been experienced from the results obtained in England and other countries where the *practice* has been introduced. A writer in *La Semaine Médicale* makes out that from 23,000 medical men in England to whom questions on a certain subject were recently forwarded only 1500 replies were received, and of this figure, which is very small, several hundreds were considered worthless, as the cases brought forward did not seem to be founded on precise personal observation. In Germany, according to a report recently read by Dr. S. Guttmann before the Medical Society of Berlin, the results obtained by a collective investigation were still less satisfactory; it was with great difficulty that the committee could collect 200 replies of any value out of those from 16,000 medical men practising in the country. It has therefore been decided to address to the medical practitioners in Germany a more simple form of questions. In Italy it is nearly the same as in Germany, and in France it is anticipated that matters will not be any better. But whatever form of inquiry be adopted on the present occasion—that is, on the contagiousness or non-contagiousness of tuberculosis,—it would be equivalent to a medical "plebiscite," and the writer referred to alleges that, however useful figures may be in other cases, they are of little or no value in scientific questions, and cannot therefore be made law. The greater or smaller number of replies, favourable or unfavourable to the contagiousness of this malady, will only prove that this contagion exists or does not exist in reality. It will therefore simply be a document which may *contribute* in some measure to the solution of the question, but this solution may be obtained by the adoption of other means, which, however, the writer has omitted to mention.

CREMATION IN FRANCE.

Cremation is gradually being introduced into this country, and will soon become recognised as a legal mode of disposing of the dead. At the last meeting of the Council of Hygiene, Professor Brouardel, who was charged to report on the measure, proposed to establish a crematory at Père la Chaise, to be employed as a commencement for the incineration of bodies that have been used for anatomical purposes. The following is a summary of Dr. Brouardel's report on the subject: 1. As regards salubrity, the establishment of a crematory apparatus in the cemetery of Père la Chaise would present no danger. 2. Three apparatus working for eight hours would be sufficient to destroy the debris of corpses. 3. It will be necessary to establish a separate mortuary room, so as to prevent any delay in the prompt disappearance of the débris.

PARISIAN VITAL STATISTICS.

In the statistical report which has just been published by the Prefect of the Seine for the year 1884, it is shown that there have been in Paris 63,060 births, 20,424 marriages, and 55,555 deaths, 5746 of which were caused by zymotic diseases, 10,653 by pulmonary phthisis, 5105 by bronchitis and pneumonia, and 34,051 by other causes. In short, the number of deaths was 56,616, or 1061 more than that of last year. Population, 2,239,928.

Paris, Feb. 25th.

MACCLESFIELD GENERAL INFIRMARY.—At the twelfth annual meeting of the subscribers to this institution, which was held on the 19th inst., it was decided that the engagement of the house-surgeon should be terminable by one month's notice, instead of by three as heretofore, and it was also resolved that the matron shall superintend the establishment in conjunction with the house-surgeon, an office hitherto filled by the latter official alone.

MAHOMED MEMORIAL FUND.

THE following additional subscriptions have been received or promised:—

	£	s.	d.
Sir Thomas Acland, Bart.	10	0	0
R. T. Bedford, Esq.	1	1	0
W. Crosbie, Esq.	1	1	0
E. Montague Day, Esq. ...	1	1	0
Dr. Walter Edmunds ...	2	2	0
Dr. A. L. Galabin	5	5	0
Dr. Longstaffe	2	0	0
F. G. Larkin, Esq.	1	1	0
Henry Moon, Esq.	15	15	0
Dr. T. Morton	2	2	0
R. J. Pye-Smith, Esq. ...	1	1	0
Dr. H. Sutherland	1	1	0
Frederick Wallace, Esq. ...	1	1	0

The treasurer or hon. secretaries would be glad to receive the names of any who still wish to contribute to the fund, inasmuch as a meeting of the committee will shortly be held, at which it is desirable to present as full a statement as possible.

ARTHUR E. DURHAM, Treasurer.
JAMES F. GOODHART, } Secretaries.
W. H. A. JACOBSON, }

MEDICAL NOTES IN PARLIAMENT.

Scarlet Fever in a Training Ship.

IN the House of Commons on the 23rd inst., Mr. Caine, in reply to Mr. Halsey, stated, with respect to the outbreak of scarlet fever in the *Britannia*, that the number of cadets in the hospital at Dartmouth was twenty-four. All were doing well. Every investigation was being made as to the cause of the outbreak, which was of a very mild character.

Small-pox and Vaccination.

On Thursday, Mr. G. Russell, replying to Mr. Picton, said he was aware that in Leicester, Keighley, Dewsbury, and other towns, there is a large number of persons who are in default under the Vaccination Acts on account of non-vaccination of their children. In these towns, and in some three or four others where there has been no recent experience of small-pox epidemics, there is no doubt that a strong anti-vaccination feeling exists; but although these places have for some years past been practically free from small-pox, the same may be said of many other towns. London had suffered from severe epidemics, and small-pox had been prevalent in Birmingham, but in London especially epidemics were dependent on a number of conditions besides the universality of infantile vaccination. More to the purpose than a proposal to compare small-pox incidence in particular towns is a comparison between the incidence of small-pox upon the vaccinated and upon the unvaccinated, when small-pox became epidemic in a town. He had no evidence of any general increase of a feeling of resistance to the Vaccination Acts. The last returns showed no falling-off as regarded the proportion of children vaccinated, less than five per cent. of the children born being reported as unaccounted for. The whole subject had been fully considered by a Select Committee of the House in 1871, and he did not think there would be any advantage at the present time in a further inquiry being instituted by a commission or committee of the House.

The Medical Act Amendment Bill.

Mr. Mundella, in reply to Mr. O'Connor, said he was unable to make any definite statement with regard to his intentions with reference to the Medical Act Amendment Bill, but the matter was still under consideration.

Lunacy Law.

Mr. R. H. Fowler, in reply to Mr. Corbett, said the Lord Chancellor was about to bring in a Bill for the reform of the Lunacy Law, which would deal with the whole question, and the Government did not think, considering the extent to which the subject had been dealt with by committees, that it was necessary another committee should be appointed.

Dispensary Doctors as Land Agents.

Mr. Campbell-Bannerman, in reply to Mr. Henry, said that, as a medical officer of a district is not bound to give his whole time to the duties of his office, it would not be illegal, although it was not usual, for him to act as a land agent. If, however, it was shown that a medical officer undertook work of any kind which interfered with his official duties, the Irish Local Government Board would take such steps as it deemed necessary to secure due attention to the sick poor.

Medical News.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on the 19th inst.:—

Botham, Richard Henry, King's College.
Cherry, George A., Toronto, Canada.
Hocken, James Preston, Charing-cross Hospital.

DR. CECIL WESTROPP has been placed on the Commission of the Peace for the county of Fermanagh.

THE salary of Mr. J. Gray, assistant medical officer of Islington Workhouse, has been increased from £100 to £110 per annum.

A DRAMATIC performance was given on the 20th inst. at St. George's Hall, Langham-place, in aid of the funds of the North-West London Hospital.

A SMALL hospital for Jewish children has been opened by Dr. Young in the Ghetto at Rome, in connexion with the medical mission he conducts in that quarter.

A NEGRO has confessed that he set fire to the lunatic asylum in Philadelphia at the instigation of one of the attendants, who had quarrelled with the superintendent.

DR. SULLIVAN of Kingston, Ontario, who was last year president of the Canada Medical Association, has been appointed by the Government a Life Senator of the Dominion of Canada.

ROYAL INSTITUTION.—Professor Arthur Gamgee, M.D., F.R.S., Fullerian Professor of Physiology, R.I., will on Tuesday next, March 3rd, begin a course of twelve lectures on Digestion and Nutrition.

OLD EPSOMIANS will hear with deep regret of the death of Sergeant Daniel Gough, who from 1858 to 1885 occupied the post of drill instructor at the Royal Medical College, Epsom.

WESTMINSTER HOSPITAL.—The Duke of Westminster will lay the corner stone of the new medical school now being erected in Caxton-street, Westminster, at three o'clock to-day (Saturday).

PRESENTATION.—Dr. Atkinson, late assistant medical officer to the Kensington Infirmary and Workhouse, was on the 19th inst. presented with a clock and bronzes by the nurses of the institution and others.

SHARMAN AND OTHERS *v.* GILLIES.—The arbitrator to whom this matter was referred to ascertain the damages sustained by Messrs. Sharman, Harris, and Clark, has assessed them at £300, and directed Mr. Gillies to pay this sum together with the costs of the reference.

A CONCERT was held at the London Temperance Hospital, Hampstead-road, on the 16th inst., the object of the gathering being to increase the public interest in the National Temperance Bazaar to be held in May next, in aid of the funds for the completion of the new wing of the institution.

NATIONAL AID SOCIETY.—The above Society is sending out more medical aid for the wounded, in connexion with the Egyptian expedition. Mr. W. Lake and Mr. F. C. Piggott left in the *Ganges* on the 26th inst.; Mr. C. H. Newby, F.R.C.S., sails in a day or two; and Dr. Squire will leave for the same destination, Suakim, in a few days.

VICTORIA HOSPITAL FOR CHILDREN.—The Committee of Management of this institution, prevented hitherto by lack of funds, have at length resolved to erect a new out-patient wing, on land already the freehold property of the charity, at a cost of £6550, of which £3000 have already been subscribed. The memorial stone will be laid by H.R.H. the Princess Louise, and the ceremony will take place in June.

ROYAL HOSPITAL FOR CHILDREN AND WOMEN.—On the 20th inst., at the annual general court of governors of this hospital, it was stated that there had during the past year been a considerable increase in the out-patient department, and an increase in the number of in-patients, and also in that of home visits to sick children. It having become necessary to entirely reconstruct the sanitary arrangements and drainage of the hospital, at a cost of £300, the committee appeal to the public for funds, both for this work and to clear off the present deficit of £400.

UNIVERSITY COLLEGE, LONDON.—At the annual general meeting of members of the College the following gentlemen were admitted as Life Governors: Rev. Henry Allon, D.D.; Prof. Cassal, LL.D.; Prof. Berkeley Hill, M.B.; Prof. Lodge, D.Sc.; George Palmer, Esq., M.P.; R. S. Poole, Esq., LL.D; Prof. G. Croome Robertson, M.A.; Prof. Schurman, D.Sc.; Right Hon. G. O. Trevelyan, M.P.; and R. Wormell, Esq., D.Sc.

THE DARENTH CAMP HOSPITAL.—At a meeting of the St. Pancras vestry on the 18th inst., a resolution to the effect that, having regard to the unsatisfactory statements prevailing relative to the management of hospitals and other institutions under the Metropolitan Asylums Board, the vestry respectfully urges upon the Local Government Board the necessity of immediately holding an inquiry into such management, was unanimously adopted.

ROYAL COLLEGE OF SURGEONS.—Professor Charles Stewart, M.R.C.S., will commence his course of three lectures on the "Structure and Life History of the Hydrozoa," in the theatre of the College, on Monday next, the 2nd prox.; and on the following Monday he will be succeeded by Prof. Alex. Hill, M.B., M.R.C.S., who will deliver the first of three lectures on the "Grey Masses of the Cerebro-Spinal System, their relations to one another and to the Peripheral Nerves." These lectures will be delivered on Mondays, Wednesdays, and Fridays, at four o'clock each day.

DEATH FROM HURRY AND EXHAUSTION.—On Saturday last Dr. Danford Thomas held an inquiry respecting the death of Professor Thomas Croxon Archer, aged sixty-nine, Director of the Museum of Science and Art, St. Margaret's, Edinburgh. The Professor, who was staying at the Midland Hotel, St. Pancras, was hurrying to catch a train, and when in the act of kissing one of his daughters fell backwards on the floor and expired. Dr. John J. Hartnett, surgeon to the hotel, was called in, and found the patient quite dead. From a history of rheumatic fever and a well-marked arcus senilis, Professor Archer must have suffered from a weak and fatty heart, and the excitement of the moment brought on the syncope which proved fatal. Attention to the warning given in our last issue might in this case have saved a valuable life.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

CLAYTON, WILLIAM KITSON, L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer for the Inkberrow District of the Alcester Union, vice Green, resigned.

COCKS, HORACE, M.B., C.M.Edin., has been appointed Junior Assistant Medical Officer to the Norfolk County Asylum, Thorpe, near Norwich.

DAVIES, D. REES, M.B. & C.M.Ed., has been appointed Medical Officer of Health for the Borough of Aberystwith.

DAVIES, MORGAN, M.D., C.M.Aber., L.R.C.P.L., M.R.C.S., has been appointed Assistant Medical Officer to the Infirmary of the Whitechapel Union, vice Voss, resigned.

GOSTLING, THOMAS PRESTON, L.R.C.P.Lond., M.R.C.S., L.S.A.Lond., late House-Surgeon and Senior Obstetric Assistant to University College Hospital, has been appointed House-Physician.

HERSCHELL, GEORGE, M.D.Lond., has been appointed Honorary Physician to the Farringdon General Dispensary.

HURLEY, JAMES, M.D., M.Ch. Q.U.I., has been appointed Medical Officer for the Queen Camel District, Wincanton Union, vice M'Clure, resigned.

KERR, ELIAS W., M.B., M.Ch.T.C.D., L.M.K.Q.C.P.I., has been appointed Medical Officer for the Fourth District of the Cerne Union, vice Greenwood, resigned.

LIDDELL, JOHN, M.B., C.M.Ed., has been appointed Medical Officer for the First (A) District of the New Winchester Union, vice England, resigned.

LOCKWOOD, HARRY, M.R.C.S., L.S.A.Lond., Senior Assistant House-Surgeon to the Sheffield Public Hospital and Dispensary, has been appointed House-Surgeon, vice Sinclair White, M.D., F.R.C.S., appointed Medical Officer of Health to the Borough of Sheffield.

MAURICE, WILLIAM JAMES, B.A.Oxon., M.R.C.S., L.R.C.P.Lond., has been appointed Surgeon to the Reading Dispensary.

PARSLOE, HENRY HEATH, L.R.C.P.Ed., M.R.C.S., has been appointed Medical Officer for the Shibbear District of the Torrington Union, vice Jones, resigned.

ROCH, SAMPSON, Deputy Surgeon-General, M.R.C.S., has been appointed Medical Officer of Health for the Cheltenham Urban Sanitary District.

SYMONS, J. GEO. RENNY, L.R.C.P.Ed., M.R.C.S., has been appointed Medical Officer to the Workhouse, Holsworthy Union, vice Pearce, deceased.

Births, Marriages, and Deaths.

BIRTHS.

BERRY.—On the 20th inst., at Queen's-road, Watford, the wife of F. Haycraft Berry, M.B., of a daughter.

COBBETT.—On the 23rd inst., at Auckland, New Zealand, the wife of Dr. Charles Newberry Cobbett, of a daughter.

HOUGHTON.—On the 16th inst., at Amersham, Bucks, the wife of Lambert Houghton, L.R.C.P. &c., of a son.

MARRIAGES.

BARNES—WATKINS.—On the 5th inst., at All Saints, Malabar Hill, Bombay, by the Rev. F. L. Sharpin, M.A., Surgeon Raglan W. Barnes, Her Majesty's Medical Staff, only son of J. Wickham Barnes, Esq., F.R.C.S., of Gower-street and Stanwell Moor, Middlesex, to Ethel Bretwalda, second daughter of G. Watkins, Esq., of Richmond, Surrey.

CARTER—BEAUMONT.—On the 12th inst., at Chudleigh, Devon, by the Rev. Walter Moyle, M.A., cousin of the bride, assisted by the Rev. Theophilus Bennett, M.A., T. E. Carter, Esq., M.B.Lond., of Stamford, Lincolnshire, to Edith Cecilia, youngest daughter of the late Col. Wm. Beaumont, of Her Majesty's Indian Army, and of Fairfield, Chudleigh, Devon.

DANE—YATE.—On the 27th ult., at Morar, Central India, Arthur H. C. Dane, M.D., son of Surgeon-Gen. Dane, C.B., to Isabella Francis, second daughter of the late Rev. Charles Yate, Rector of Holme, Yorkshire.

GREEN—HAWKINS.—On the 16th inst., at Holy Trinity Church, Bournemouth, J. Lardner Green, M.R.C.S., of Salisbury, to Eliza Ann, daughter of Francis Hawkins, Esq., of Palmerston Lodge, Bournemouth, and formerly of Tintinhull Court, near Yeovil, Somerset.

MUIRHEAD—WAGON.—On the 16th inst., at St. Peter's Church, Aylesford, Islay B. Muirhead, M.A., M.B., second son of the late John Wm. Muirhead, solicitor, Glasgow, to Edith Caroline, second daughter of Silas Wagon, merchant, Forstal, Aylesford.

STIRLING—RUNDER.—On the 16th Dec., at St. Peter's Church, Brighton, W. Boughton Stirling, M.D., to Mary Jane Runder, of Buckhurst-hill, Essex, and Brighton.

DEATH.

BARNETT.—On the 4th ult., at Tintilara, Australia, Dr. J. K. Barnett, second son of the late Horatio Barnett, of Bescot Hall, Staffordshire.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

Monday, March 2.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M. each day, and at the same hour.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M. each day, and at the same hour.
ST. MARK'S HOSPITAL.—Operations, 2 P.M., and on Tuesdays at the same hour.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
ROYAL INSTITUTION.—5 P.M. General Monthly Meeting.
ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.—8 P.M. Casual communications by Messrs. Oakley Coles, W. St George Elliott, W. Hern, W. A. Hunt, Alexander Cartwright, and Newland Pedley.—Mr. E. Charlesworth: Fossil Teeth of Extinct Animals in the Museum of the Odontological Society.
MEDICAL SOCIETY OF LONDON.—8 P.M. General Meeting. Election of Officers and Council, the ballot closing at 9 P.M.—8.30 P.M. Dr. Allchin: The Diet of the Febrile State.
ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—8.30 P.M. Annual Meeting. Election of Officers and Council. President's Address.

Tuesday, March 3.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 P.M., and Thursdays at 2 P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M., and on Fridays at 2 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ROYAL INSTITUTION.—3 P.M. Prof. Gamgee: Digestion and Nutrition.
PATHOLOGICAL SOCIETY OF LONDON.—8.30 P.M. Dr. Semon and Dr. Payne: Rhino-scleroma.—Mr. Eve: (1) Lympho-sarcoma of Bladder; (2) Enchondroma of Pelvis (card).—Dr. Hobson: Congenital Obstruction of Intestine.—Dr. Turner: (1) Neuro-sarcoma of Brain; (2) Aneurism of Aora opening into Œsophagus (card); (3) Necrosis of Renal Pelvis (card).—Mr. Lane: Unusual form of Pott's Fracture.—Dr. Silcock: Intercular Pyo-Salpinx.—Dr. Hale White: (1) A case of Renal Disease; (2) A Cryptorchid diving.—Mr. D'Arcy Power: Synovial Cysts in connexion with Joint Disease.—Mr. John Poland: Ununited Fracture of Internal Condyle of Humerus (card); Mr. Jonathan Hutchinson, jun.: Lupus Lymphaticus (card).—Dr. Beevor: Nerve Tissues Stained by Weipert's New Method (card).—Mr. M. Sheild: Tumour of Humerus (card).—Mr. C. Gross: Œsophagus and Parts from Fatal Case of Sword Swallowing.—Mr. Bruce-Clarke: (1) Unilateral Distribution of Warts (living); (2) Croupous Enteritis of Ileum (card).

Wednesday, March 4.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M., and on Saturday at the same hour.—Ophthalmic Operations on Tuesdays and Thursdays at 1.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Skin Department: 9.30 A.M., on Tuesdays and Fridays.
ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M., and on Saturday at the same hour.
LONDON HOSPITAL.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.
GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M., and on Saturday at the same hour. Skin Department: 1.45 P.M., and on Saturday at 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M.
KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.
OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Specimens will be shown by Dr. Herman, Dr. Horrocks, Mr. W. S. Griffith, and others.—The President (Dr. Potter) will deliver the Inaugural Address.—Adjourned Discussion on Dr. Wm. A. Duncan's paper on Extirpation of the Uterus, to be opened by Sir Spencer Wells, Bart.—Dr. Murphy: Sequel to a case of Ovariotomy.

Thursday, March 5.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Surgical Consultations, 1.30 P.M.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.
NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ROYAL INSTITUTION.—3 P.M. Prof. Dewar: The New Chemistry.
HARVEIAN SOCIETY OF LONDON.—8.30 P.M. Mr. T. W. Carmalt Jones will show an Instrument for the Transfusion of Defibrinated Blood.—Dr. C. Y. Biss: Notes of a Case of Pleuro-pneumonia in a Child, with an unusual course and symptoms.—Dr. C. J. Hare: Emetics, their Present Neglect in the Treatment of Disease.

Friday, March 6.

ST. GEORGE'S HOSPITAL.—Ophthalmic Operations, 1.30 P.M.
ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.
KING'S COLLEGE HOSPITAL.—Operations, 2 P.M.
WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—8 P.M. Mr. Percy Dunn: Morbid Specimens.—Mr. Menzies: Various Clinical Cases.—Dr. Thorowgood: A case of Enteric Fever followed by Abdominal Abscess, with Double Perforation of the Diaphragm and Discharge of Pus through both Lungs.—Dr. Herringham: A case of Descending Lateral Sclerosis in a Child, probably from lesion of right crus cerebri.
ROYAL INSTITUTION.—9 P.M. Mr. C. T. Newton: German Discoveries at Pergamus.

Saturday, March 7.

KING'S COLLEGE HOSPITAL.—Operations, 1 P.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M.
ROYAL INSTITUTION.—3 P.M. Mr. C. Armbruster: Richard Wagner.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe, or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

DEATH CERTIFICATES AND CASES OF INJURY.

Inquisitor.—The Registration Act of 1874 requires every registered medical practitioner to certify the cause of the death of any person attended by him during his last illness according "to the best of his knowledge and belief." The law does not *require* the medical practitioner to report any case of violence to the coroner, but it is undoubtedly expedient, in the interest alike of the public and the profession, when a deceased person has recently suffered from any kind of injury, that this fact should be stated in the medical certificate, even if in the opinion of the certifying practitioner it did not contribute to the death. The suppression of such a fact might be misunderstood by the coroner, in case an inquest were subsequently held. It would be the duty of the registrar, on being applied to to register the death, if he heard of the supposed injury, to report the case to the coroner, even if the fact of such injury was not stated in the certificate.

Mr. C. H.—It would, we think, be a great mistake to give such a reviewer greater publicity by inserting his note and impertinent proposal in THE LANCET.

Dr. J. Oliver.—Probably next week.

TREATMENT OF SPINAL INJURY BY EXTENSION.

To the Editor of THE LANCET.

SIR,—It gives me much pleasure to find that the treatment of spinal injury by extension under chloroform has been equally successful when adopted by Mr. Thomas Jones in the Manchester Infirmary, described in your last issue, as in a somewhat similar case of Dr. Wollaston's, which occurred during my house-surgeoncy at the Southern Hospital, Liverpool, about sixteen years ago (see THE LANCET, Jan. 23rd, 1869). It has always been a pet case of mine, as I found and helped to haul up the man from the river bed after a fall from the pier, a distance of 40 ft.

I am, Sir, yours truly,

Piccadilly, Manchester, Feb. 21th, 1885. W. R. DAMBRILL-DAVIES.

COFFEE ROASTING.

A DISCUSSION is now taking place in the pages of the *Grocer* on the best means for retail grocers to roast their own coffee. As a rule, they buy it roasted, as the usual process requires expensive apparatus and considerable skill. They are, however, beginning to be alive to the fact that their customers will not drink much coffee unless they can get it really freshly roasted. In this way the "Stores" and large dealers are generally able to out-do the small retailers, who, we should be glad to know, had found a satisfactory solution of the problem.

T. W.—We do not prescribe.

Mr. P. Ness.—The suggestion would certainly not be favourably received by the profession.

PROTECTION AGAINST SUNSTROKE.

AT the Japanese Village, Albert-gate, there is now being made by order of Government a most ingenious contrivance, which will, it is hoped, effectually protect the soldiers at present serving in the Soudan from the rays of the sun, and render an attack of sunstroke almost impossible. It is formed of light bamboo and paper, and may be thus described: On each shoulder is fixed a piece of bamboo bent in the form of an arch; in the centre of each arch a piece of bamboo somewhat resembling an umbrella-stick, eighteen inches in height, is securely fixed, and these sticks support a light awning two feet in length by eighteen inches in breadth; the frame of the awning is composed of bamboo, and the covering of paper painted green inside; the weight will scarcely be felt, and the wearer will enjoy all the comforts of a large umbrella without experiencing the inconvenience of holding it up, and his hands will be left entirely free to carry his rifle or other articles.

Dr. J. T. Shepherd (New York).—We know nothing of the ointment named.

CAFFEINE IN BRIGHT'S DISEASE.

To the Editor of THE LANCET.

SIR,—I am glad to bring before the profession an instance (among many) of the beneficial effects of caffeine and its salts in certain cases of "water-logging."

I have had a case of subacute Bright's disease (following presumably on an acute attack) under my care for some two months, with scanty, highly albuminous urine, and gradually increasing ascites and œdema of the lower part of the body and lower limbs. The only treatment which had benefited the patient in the least was the milk diet; but, in spite of a temporary improvement on this account, symptoms of approaching uræmia and the inefficacy of any medicinal treatment or hot-air baths, &c., rendered the case an anxious one. I then tried caffeine in the two forms supplied by Messrs. Burroughs, Wellcome, and Co. for use at this hospital. First the effervescent citrate of caffeine, an elegant and agreeable preparation, but which only contains a grain to a drachm, and is therefore hardly as convenient as the Wyeth's tablets, each of which contains a grain; being readily soluble, they constitute a very convenient method of administration. The result of three or four days' treatment at the rate of fifteen grains a day in three doses was to increase the flow of urine from half a pint to between three and four pints of clear urine, though still slightly albuminous. The epigastric and lumbar pains disappeared, together with the cerebral and visual troubles, and the condition of the patient has uninterruptedly improved ever since, and she has left the hospital quite convalescent.

I am, Sir, your obedient servant,

ALFRED S. GUBB, M.R.C.S., L.R.C.P.Lond.

Hôpital Français, Leicester-square, W.C., Feb. 23rd, 1885.

"AN EASY METHOD OF APPLYING THE FORCEPS."

DR. JAMES MILLAR in a letter to us describes the method he adopts as follows:—"The patient is brought conveniently near the edge of the bed, not laid across the bed, but in the usual position, or at an angle of 45°, which is preferable for various reasons. The patient's thighs being flexed on the abdomen and the lower blade introduced in the usual way, I then, leaning well over the edge of the bed, get the flexed elbow of the right arm between the patient's knees or thighs, and thus raise the upper thigh without the aid of an assistant or the patient herself. The wrist being free, the handle of the upper blade is brought well up towards the abdomen, and held lightly, like a fiddlestick, between the thumb and two fingers; the point of the blade is introduced in the axis of the outlet and along the curve of the sacrum, as described by Dr. Lewis, bearing in mind that one of the elementary principles in the employment of the forceps is that no force must be used."

Hospital, Vincent.—The hon. secretary is R. G. Salmond, Esq., 73, Cheapside, E.C.

"PRURITUS VULVÆ."

To the Editor of THE LANCET.

SIR,—Allow me to mention for the information of "M.D.," and also with reference to the remark that pruritus vulvæ associated with diabetes might be relieved by half-grain doses of codeia, that a case of diabetes mellitus has been under my treatment with grain doses of codeia for the last three months; and last week, while still taking this drug, the patient suffered from a most distressing attack of this troublesome complaint, but was completely relieved by fomentations of hot water.

I am, Sir, yours faithfully,

J. G. W. BULLOCK, L.R.C.P.Ed.

Stradbroke, Wickham Market, Feb. 21th, 1885.

GLYCERINE AS A SOLVENT FOR PODOPHYLLUM RESIN.

To the Editor of THE LANCET.

SIR,—On making some experiments a short time ago on the solubility of podophyllum resin, I found that glycerine formed a good solvent, and an unirritable vehicle for its administration. Four grains of podophyllum resin added to one ounce of glycerine gently heated till the resin dissolves, produces a clear solution, and makes a pleasant preparation.

I am, Sir, yours obediently,

Liverpool, Feb. 25th, 1885. C. J. S. THOMPSON.

PHYSIOLOGICAL EFFECTS OF MAGNETISM.

DR. OCHOROWICZ publishes in a French scientific journal some observations on the effect of a magnet on different persons. His instrument is an incomplete tube of steel, about an inch and a half in diameter and two inches and a half in length, strongly magnetised, the edges of the slit being the poles. The forefinger of the person to be examined is introduced into the instrument, so that it is in contact with both poles. It is allowed to remain for two minutes, and is then removed and observations taken of the phenomena produced. In 30 to 37 per cent. only of average persons is anything observed, 20 per cent. having itching and formication, 17 per cent. sensation of heat or of a cold blast, 8 per cent. painful sensations, 5 per cent. sensation of inflation of the skin, 2 per cent. sense of weight in the finger or arm. In addition to these subjective sensations, objective phenomena are observed—analgesia, anæsthesia, motor paralysis, rigidity of muscles, and rarely involuntary movements. Dr. Ochorowicz finds that sensitiveness to the magnet exists in the persons who have a capacity for being affected by hypnotism, which, he says, depends upon peculiar reflex relations between the cerebro-spinal and ganglionic systems, and especially between the brain and the vaso-motor nerves, this special aptitude being for the most part innate and unconnected with any disease whatever—hysteria, epilepsy, neurasthenia, or anæmia.

"THE ADMISSION OF PATIENTS SUFFERING FROM FITS TO ASYLUMS FOR IDIOTS."

To the Editor of THE LANCET.

SIR,—Referring to Earlswood Asylum in your issue of the 21st inst., Dr. J. R. White writes: "The majority of the patients in that asylum are subject to fits." This statement calls for correction from me. Of 579 patients at present in this asylum, 143 (rather less than 25 per cent.) are subject to epilepsy. We have no hard-and-fast rule rendering epileptics ineligible, but the circumstances of each case are carefully considered by the Board of Management. Recent and possibly curable epilepsy would not be regarded as a disqualification, but confirmed epilepsy usually renders its victim incapable of improvement under the system of education and industrial training, the due carrying out of which was the primary object of the founders of the charity. Every patient thus afflicted who is maintained here fills a bed which might be occupied by an educable patient capable of profiting by the instructions of our large educational staff. Epilepsy leads often to maniacal attacks, and usually, sooner or later, to dementia. Patients suffering from these mental conditions are ill suited for treatment in idiot asylums, the domestic arrangements of which are rather those of large training schools or industrial homes than those of asylums for the insane. The managers of the younger idiot asylums, recognising the above facts and wishing to reserve the benefits of their institutions for improvable and educable cases, regard epilepsy as a disqualification for admission; but a few mild cases occasionally creep in. At the Metropolitan District Schools at Darenth, idiotic and imbecile children, whether epileptic or not, are received upon the order of the Poor-law Guardians of the Metropolitan Unions. Epileptic idiots and imbeciles whose friends are able to pay remunerative rates for their maintenance are sometimes received at Earlswood and other idiot asylums, but an enhanced rate of payment is usually required, owing to the extra care and attention which is necessary when epilepsy exists as a complication. For epileptic idiot children of the poorer classes (with the exception only of the metropolitan area) no suitable accommodation exists, that provided in workhouses and public lunatic asylums not being adapted to the requirements of the patients. I am, Sir, yours faithfully,

C. S. W. COBBOLD, M.D.,
Medical Superintendent, Earlswood Asylum.

Red Hill, Feb. 23rd, 1885.

"DISREPUTABLE ADVERTISEMENTS IN METHODIST PAPERS."

DR. COLEY of Newcastle-on-Tyne writes a most excellent letter to the Editor of the *Methodist Times* on the above subject. He congratulates himself that the new Methodist paper is free from the great scandal which disgraces many religious periodicals—the admission of disreputable advertisements, but says that the publications of the denomination are by no means free from reproach. Dr. Coley denounces all advertisements of sham things, whether sham jewellery or sham physic, in religious newspapers as specially discreditable; and all those who believe in "whatsoever things are true" will agree with him.

Dr. James Gairdner.—It is not our custom to enter into written communication with those whose professional conduct is impugned. We endeavour to remember and to allow for any incompleteness in the version of the facts, and to form the best judgment we can. We see no essential difference between ourselves and Mr. Styrap.

ALCOHOLISM.

To the Editor of THE LANCET.

SIR,—I am anxious to obtain all the information available on the subject of leg and other pains due to alcoholism. Could you or any of your readers kindly direct me to the best and latest authorities, English or foreign? I am, Sir, yours faithfully,

Feb. 23rd, 1885. ENQUIRER.

THE LATE MR. CÆSAR HAWKINS.

A CORRESPONDENT calls our attention to a few errors in the brief sketch of the life of the late Mr. Cæsar Hawkins included in the Hunterian oration published in our last number. Mr. Cæsar Hawkins was not the grandson of Mr. Charles Hawkins, but his nephew; he was the grandson of Sir Cæsar Hawkins, the first baronet in the family. He was never assistant-surgeon to St. George's Hospital. The statement that he was partially trained in the school of Great Windmill-street is inaccurate, as that was his only school; and he lectured there, not "late in life," but at the age of twenty-eight. Then, again, he was not the last of his family in the profession; the Roll of the College of Surgeons still contains a Cæsar Hawkins, a descendant of the first Sir Cæsar Hawkins (see the obituary notice of Mr. Cæsar Hawkins in THE LANCET of July 26th, 1881).

Country Surgeons' question is too vague to admit of a definite reply. What is meant by a "poor person?" and what was the reason assigned for the refusal of an order?

Mr. R. T. Smith (University College).—The matter is engaging our attention. We hope ere long to examine a series of the preparations mentioned, and shall be able to utilise the experiments of our correspondent.

SCHOOLS FOR IMBECILES.

To the Editor of THE LANCET.

SIR,—In reply to "F. F. G.'s" query in your last issue, may I be allowed to suggest that the child to whom he refers might probably derive benefit from training in one of the special institutions for imbeciles, which are, in fact, schools for children of peculiar and defective mental constitution. The Royal Albert Asylum at Lancaster (which has special accommodation for payment cases) is within easy range of your correspondent's address, and he would receive full information as to terms of admission on application to the secretary.

I am, Sir, yours faithfully,

Feb. 24th, 1885. M.D.

DEATHS FROM LIGHTNING IN FRANCE.

THE bulletin of the Association Scientifique de France says: "Lightning has killed 4609 persons in France alone since 1835. An equal number have been seriously, though not fatally, wounded, and five times as many struck. The hot years were the most fatal, and these are remarkable as having been the best wine seasons. There has not been a single death from lightning in Paris or the Department of the Seine since 1884, though there have been many violent storms there during that time.

H. C. has not enclosed his card.

Mr. G. E. Walker.—We shall be glad to receive the paper.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Mr. A. T. Norton, London; Sir J. Fayrer; Dr. Bristowe; Mr. Rushton Parker, Liverpool; Dr. Glaister, Glasgow; Dr. R. J. Lee, London; Dr. R. Sinclair, Dundee; Mr. Reginald Harrison, Liverpool; Dr. Osler, London; Dr. S. Cobbold, London; Dr. Herbert Stowers, London; Mr. Dambrill Davies, Manchester; Mr. Whitefoord, London; Mr. E. S. Pearse, Brierley Hill; Mr. Patrick Ness, London; Mr. B. Thorpe, Middleton; Dr. Ewart, London; Mr. Campbell Hyslop, Church Stretton; Mr. Bullock, Stradbrooke; Dr. Longshore Potts; Dr. Doyle, Christchurch, N.Z.; Dr. Campbell Pope, London; Dr. Allchin, London; Lady John Manners; Mr. Hawkins-Ambler, Leeds; Mr. Hestor, London; Dr. J. Millar; Messrs. H. B. Amerling and Son, Williamsport; Mr. Buhicrosan, London; Mr. C. Day, London; Mr. G. R. Walker, Liverpool; Messrs. Christy and Co., London; Mr. W. Brown, Carlisle; Dr. T. R. Lewis, Bywood; Mr. Mackie, London; Mr. Alfred Wright, Romford; Mr. Birchall, Liverpool; Mr. Davies; Mr. Fry, Swindon; Mr. Hutton; Mr. Fleming, Rotherham; Messrs. Wood and Co., New York; Mr. Scott, Westray; Mr. Weymouth, London; Messrs. Newman and Co., London; Mr. Fox, Bristol; Dr. Campbell Black, Glasgow; Messrs. Gulstonian Lectures
ON
MALIGNANT ENDOCARDITIS.

Delivered at the Royal College of Physicians.

BY WILLIAM OSLER, M.D.,
PROFESSOR OF CLINICAL MEDICINE AT THE UNIVERSITY OF PENNSYLVANIA, PHILADELPHIA.

LECTURE I.

MR. PRESIDENT AND GENTLEMEN, — It is of use from time to time to take stock, so to speak, of our knowledge of a particular disease, to see exactly where we stand in regard to it, to inquire to what conclusions the accumulated facts seem to point, and to ascertain in what direction we may look for fruitful investigations in the future. With your permission, Sir, I propose to do this in the case of that most interesting disease generally known as ulcerative endocarditis, a disease the phenomena of which were first clearly explained by the late Dr. Kirkes, from whose investigations in 1851-52 we date our accurate knowledge of the affection. Some of those who listen to me to-day can doubtless recall, and recall with pleasure, the Gulstonian Lectures of 1851, in which Dr. Ormerod dealt so fully and so ably with valvular affections of the heart; but a reference to them will show how much the past twenty-five years have done to widen our view of cardiac disease, more particularly in regard to the effects of emboli and the association of valvular inflammation with grave constitutional disorder, and the probable connexion of the disease with the presence of micro-organisms. By the labours of Drs. Ogle, Wilks, Simpson, Moxon, Bristowe, and others in this country, of Charcot, Vulpian, and Lancereaux in France, and of Virchow and a host of observers in Germany, a large amount of material has been accumulated, and we may assume that the etiological, clinical, and anatomical characters of the disease have been fairly well ascertained, and that we have got about as far towards a full knowledge of the affection as the ordinary means at our disposal will permit. The inquiry now enters upon another stage, and it remains for experimental investigation to determine, if possible, the relation of the endocarditis to those diseases with which it is most frequently associated. This being the case, the present time has seemed to me a favourable opportunity to summarise our knowledge to date, and for this purpose I have reviewed the records of over two hundred cases, which, from the description of the symptoms and lesions, were evidently of the type of malignant endocarditis; and these, with the considerable experience I have had at the General Hospital at Montreal, may perhaps enable me to give a somewhat more comprehensive account, in some respects, than has yet been attempted.

In discussing the subject of endocarditis we are met at the outset by difficulties of nomenclature and classification. The designation *acute* may be used to indicate those forms which are accompanied by proliferation of and exudation upon the endocardial surface, with or without loss of substance, as opposed to *chronic*, in which there are sclerotic changes without vegetations. Subdivisions of the acute form have been arranged on an anatomical basis as the terms *plastic*, *papillary*, *verrucose*, *fungous*, *ulcerative*, indicate. On the other hand, from an etiological point of view, the forms of endocarditis are as numerous as the diseases in which it occurs, and we constantly hear the expressions *puerperal*, *rheumatic*, *scarlatinal*, &c. Some speak of primary and secondary forms, while from a clinical standpoint they are arranged in two classes, simple and grave. Anatomically there appear to be no very essential differences in the various forms of acute endocarditis. Between the small papillary excrescence and the huge fungating vegetation with destructive changes all gradations can be traced, and the last may be the direct outcome of the first; the two extremes indeed may be present in the same valve. They represent different degrees of intensity of one and the same process. A classification of cases based on the ordinary macroscopic characters of the inflammatory products into warty or verrucose and ulcerative will in many instances group together cases widely different in their clinical aspects, and, contrariwise, a clinical subdivision into cases of simple and cases of malignant endocarditis by no means of necessity implies that the lesions in the former case are all of the plastic or warty variety, and in the latter of the ulcerative or destructive. The term *ulcerative* has come into very general use to describe the grave form, and it expresses well an anatomical feature present in a large proportion of cases; but in others it is very inapplicable, as there may be no actual loss of substance, and no more destruction than occurs in the verrucose form; and, on the other hand, there may be great destruction and ulceration from causes of an entirely different nature. The numerous other terms employed, *septic*, *infectious*, *diphtheritic*, *mycosis endocardii*, *arterial pyæmia*, while each expressing some special feature, and so far suitable, have never come into very general use. On the whole, it seems to me that the names *simple* and *malignant*, which we use so often to separate the milder and severe forms of many diseases, might appropriately be employed in describing the cases of acute endocarditis; the *simple* being those with few or slight symptoms, and which run a favourable course; the *malignant* the cases with severe constitutional disturbance and extensive valve lesions, whether ulcerative or vegetative, the term being more clinical than anatomical.

Malignant endocarditis occurs under the following conditions:—1. As a primary disease of the lining membrane of the heart or its valves, either attacking persons in previous good health or more often attacking the debilitated and dissipated or those with old valve lesions. 2. As a secondary affection in connexion with many diseases, particularly rheumatic fever, pneumonia, scarlet fever, diphtheria, ague, &c. 3. As an associated condition in septic processes, traumatic or puerperal. We shall discuss first the anatomical characters, then the clinical features, and lastly the etiological and pathological relations.

The lesions of malignant endocarditis are by no means uniform, and may be vegetative, ulcerative, or suppurative; and these various forms may occur alone or in combination. The belief that there is always ulceration has led to some confusion; and we must recognise that there are cases with the clinical history of the malignant form in which, post mortem, the valvular condition has been that of a severe vegetative or verrucose endocarditis. Such a case was a lad aged eleven, a patient of Dr. Molson's, from whom I obtained the specimen which I pass round. He had chorea in July, 1880, the second attack. Rapid improvement and recovery under Fowler's solution, five minims every four hours hypodermically, took place. There was a slight murmurish condition of the first sound. When seen again on March 3rd, 1881, the chorea had returned, having begun ten days before. The patient improved until the 10th, when he began to get feverish; had exacerbations each evening; temperature rising to 104° F. He became unconscious. There was slight paresis of the left side, and death took place on the 16th. The temperature on the 15th was nearly 106°. There were irregular, soft, greyish-white vegetations on the mitral valve, infarcts in spleen and kidneys, and a small spot of red softening in the right corpus striatum. These photographs from a case of Dr. Musser's illustrate a more advanced condition of the same kind; the vegetations were larger, more abundant, and some were a little irregular and soft on the surface, but unless a mass was removed no actual loss of substance was seen. Even in the smallest vegetation there is some destruction of endocardial itssue, if only of the endothelium and superficial layer, while the larger outgrowths are more deeply set in the valve, or may involve the entire thickness. More commonly with or without vegetations there is ulceration, the frequency of the occurrence of which has given the name most often attached to this form of endocarditis. The loss of substance may be superficial, involving only the endocardium, or it may be deep and destructive, leading to perforation of a valve, of the septum, or of the heart itself. On the valves extensive outgrowths usually accompany the process, and may conceal the ulcer or project as fungating masses from its edge, as is well illustrated by this coloured drawing. In many instances the process appears simply ulcerative, without any vegetations to speak of. In the slightest form only a superficial abrasion exists, perhaps scarcely recognisable, in others a process of erosion may go on by which half a valve may be destroyed, or there may be (as shown in this drawing) a deep excavation extending beyond the valves and destroying the muscle substance of the heart, leading to

perforation of the septum or of the wall of the ventricle. These are well-known features, however, upon which I need not dwell. In two instances I have seen superficial necrotic changes without ulceration or vegetations, circumscribed patches, the size of a sixpence, opaque yellow-white in colour, resembling the necrotic pleura, over a pyæmic infarct of the lung or portion of dead peritoneum at the base of a deep typhoid ulcer. Doubtless these would in time have formed ulcers. I find this condition noted by one or two observers. Lastly, the process may be suppurative, in which case the deeper tissues of the valve appear first involved and the endocardium only implicated by contiguity. The occurrence of small abscesses at the base of extensive vegetations is not uncommon, but there are also instances in which the suppuration seems the initial step. The combination of ulcerative and fungating outgrowths is perhaps the most common condition. The vegetations vary a good deal in appearance and consistence. Soft greyish-white masses with roughened friable surfaces, to which thin blood-clot adheres, are numerous; or there may be large cauliflower excrescences with deep jagged fissures; or, again, long pendulous stalactitic masses. In the latter form we often see, as Dr. Moxon pointed out, the effects of friction, and such a long vegetation from an aortic cusp may produce by contact a whole series of smaller outgrowths along the ventricular wall. The pressure of the valves against each other and the action of the blood tends to loosen and break the vegetations, and one can sometimes see where masses have been torn off either entire or by a gradual process of disintegration. Considering the force with which the valves come together it is curious that the soft vegetations, occupying as they generally do the lines of closure, can resist the constant compression to which they are subjected. Some vegetations present a remarkable greenish-grey or greenish-yellow colour. Changes in a conservative direction may go on when the disease is much prolonged. Fibroid induration may take place in the deeper parts, while the superficial portions remain unchanged and necrotic, perhaps also getting a little harder and shrinking. Such a process can be seen in this specimen of endocarditis from an ox, in which there were most extensive vegetative and destructive changes. Not unfrequently the vegetations are gritty from the deposit of lime salts, which may take place in very acute cases, and is not necessarily an indication of age. It is interesting to note how often inorganic material is deposited in the neighbourhood of micro-organisms, as here on the endocardial outgrowths, in the tonsillar crypts, and about the tufts of actinomyces. Two conditions must be distinguished from the lesions of malignant (mycotic) endocarditis: the atheromatous degeneration in sclerotic valves, which leads to ulceration and extensive destruction of segments; a process which has nothing in common, except in its effects upon the valves, with the acute ulcerative changes above described, but is similar to the atheromatous processes in the aorta. It must not be forgotten, however, that an acute mycotic process may be engrafted, and indeed often is, upon old sclerotic valves, the seat of atheromatous changes. The firm white globular thrombi of the auricular appendices and of the interstices of the columnæ carneæ of the ventricles have sometimes an appearance closely resembling endocardial outgrowths, and when softened in the centre and ruptured the resemblance may be very close indeed. It is possible that the granular débris of an atheromatous abscess or a softened thrombus may possess irritating properties when discharged into the blood.

Histological characters.—The study of a small fresh endocardial vegetation shows it to be made up of cells derived from the subendothelial layer, round and fusiform, which by their proliferation have produced a small nodular projection on the surface of the endocardium. Varying with the rapidity of the growth, the mass will present the characters of a soft granulation tissue or a tolerably firm fibrous outgrowth. Usually the round cells predominate, but there may be many elongated, spindle-formed cells with three or four processes. What part the endothelium plays in this growth has not been determined. Tiny outgrowths may be seen in which the process appears to be entirely subendothelial, but usually before the mass attains any size the smooth surface is lost, and there is deposited upon it a cap of fibrine in the form of a granular, sometimes stratified, material, of variable thickness. Though this resembles an ordinary coagulable exudation, it is probably deposited directly from the blood, and is of the nature of a thrombus. Upon and in this layer may be found, sometimes in large numbers, those remarkable little bodies which have so long been known, when collected together, as Schultze's granule masses, and which have of late become so prominent as the blood-plates of Bizzozero and the hæmatoblasts of Hayem. Occasionally they are very abundant, and I have seen soft warty vegetations composed (superficially) in great part of them. As their connexion with endocardial and endarterial outgrowths has not, so far as I know, been referred to, I may be permitted to call attention to these two drawings, which further illustrate this point. The first represents the aorta from an old man dead of carcinoma, in which just above the bifurcation three irregular masses are shown, one nearly an inch in length, which projected fully a quarter of an inch from the intima of the vessel. They were attached to atheromatous ulcers, were soft greyish-white in colour, and were composed exclusively of the elements of Schultze's granule masses, with fibrine fibrils, and here and there a few white corpuscles. The second drawing illustrates a small aneurysm of the aorta, which has perforated the œsophagus. On the wall of the sac the artist has represented a number of irregular whitish lines, which were narrow elevated ridges, also made up microscopically of these small discoid elements, the connexion of which with fibrine formation has been so strongly insisted upon by Bizzozero. Scattered in and beneath the fibrinous exudation are numerous small granular bodies, which have the appearance and reaction of micrococci.

The larger vegetations, more characteristic of malignant endocarditis, consist of a granular material composed of altered and dead tissue elements, fibrinous exudation, and colonies of micrococci; the deeper parts present the appearance of a granulation tissue, while at the attachment in the valve there is always more or less infiltration and increase of the cell elements. The granular substance is structureless, and resembles diphtheritic exudation, the resemblance at times being so close that one can readily understand the application of the term "diphtheritic" to the inflammation. It may be distinctly laminated, and with a high power fine filaments can be seen, though usually the granules conceal all appearance of structure. Strands of translucent material may occur throughout the mass, as if portions had undergone a sort of hyaline transformation. In some instances this is very marked. Pale spheres filled with granules also occur, and may be very abundant. They have been described as colonies of micrococci, but some regard them as altered endothelial elements. I have seen them too numerous to be explained on this view. At the attachment of the vegetation there is a zone of tissue deeply infiltrated with leucocytes, and deeper still the tissue elements of the valve present an increase of nuclei and cells. The destruction of tissue appears to result in two ways: first, a gradual extension inwards of the necrotic process, doubtless induced by the micrococci; secondly, the softening and separation of valve tissue caused by the rapid development of leucocytes at the base of the vegetation.

The micrococci are constant elements in the vegetations. All granules of a uniform size met with in the sections are not micro-organisms, nor, indeed, are all which stain by some methods recommended for the detection of these bodies. By far the most satisfactory method is that of Gramm,[1] in which the section, after staining in gentian violet, is transferred for a few minutes to a dilute solution of iodine and iodide of potassium, and then to the alcohol, when it is found that the colour has been extracted from all tissue elements and nuclei, leaving only the micro-organisms stained. They vary a good deal in number and arrangement, and may be scattered singly in the granular substance or arranged in groups. They are usually very numerous at the deeper part of the vegetations, just where the structureless material joins the granulation tissue, and they may penetrate deeply into the substance of the valve. Sometimes the smaller vegetations seem made up exclusively of them. Several of my specimens appear to confirm the view of Klebs,[2] that the micrococci lodge first on the endocardium and penetrate into the substance, often as distinct columns. In their immediate vicinity there is a zone of necrosis, and beyond this an accumulation of leucocytes and signs of reactive inflammation. The micro-organisms found in connexion with the malignant endocarditis are not all of the same kind. Klebs distinguishes two forms, one met with in

[1] Fortschritte der Medicin. Berlin, Bd. i.
[2] Archiv. f. Experiment. Pathologie, Bd. vi.

septic, and the other in rheumatic, cases. In some instances the micrococci are all arranged in zoogloea-like masses, in others, particularly the septic cases, they are in chaplets. Some present distinct capsules. Small elongated bacilli have also been found; I have seen them in one instance—short, stout rods often joined in pairs. Delafield and Prudden[3] have recently noted the presence of bacilli in the vegetations of a very acute case of malignant endocarditis. Cornil, in a recent lecture,[4] stated that the bacillus tuberculosis had been found in the vegetations on the valves in cases of phthisis, and expressed the opinion that before long we should have accurate knowledge of a variety of micro-organisms in endocarditis depending upon the nature of the primary disease. By culture experiments alone can we hope to have the question settled.

The following figures give an approximate estimate of frequency with which different parts of the heart are affected. The aortic and mitral valves were affected together in forty-one cases, the aortic valves alone in fifty-three, the mitral alone in seventy-seven, the tricuspid in nineteen, the pulmonary valves in fifteen, and the heart-wall in thirty-three. The right heart is rarely affected alone, in only nine instances, in which five the tricuspid and four the pulmonary valves were involved. The valves are most often attacked along the lines of closure, as in the simple endocarditis, the auricular faces of the mitral flaps and the ventricular surfaces of the aortic cusps suffering most severely. Mural endocarditis is most often seen at the upper part of the septum of the left ventricle, just below the aortic ring, in which situation some of the most extensive and deep cardiac ulcers occur, leading to perforation of the septum. Next in order is the endocardium of the left auricle on the postero-external wall, as noted by Lepine.[5]

The local effects of the ulcerative changes are important. Perforation of a valve segment is extremely common, sometimes there is a clean-cut punched-out hole with scarcely any irregularity of the edges; more frequently, however, there are great fungous vegetations which completely close and conceal the perforation. Erosion of the chordæ tendineæ is frequently met with, and an entire group passing to the papilla may be destroyed, the ends curled and encrusted with vegetations. Ulceration of the heart muscle leading to perforation of the septum or of the wall of a chamber is a much less frequent occurrence. I have collected notes of eleven instances; three of the septum close to the aortic ring. Ulcers at the aortic ring perforated the left auricle in three instances, the right auricle in one and the right ventricle in one. In a remarkable case of Dr. Stephen Mackenzie[6] the left ventricle was perforated by an ulcer at the apex. In a case of Dr. Curnow[7] the ulceration extended between the coats of the aorta, and then perforated into the lumen of the vessel, and in one of the Montreal cases there was perforation of an aneurysm of the aorta by ulceration, an instance of extensive ulcerative endarteritis with the production of multiple aneurysms. Another common result of ulceration is the production of valvular aneurysm. The anterior flap of the mitral is most frequently affected, and then the aortic cusps. In the records of the cases which I have reviewed I was surprised not to find this condition noted oftener, only in about 12 per cent. of the cases; but in very many cases the record of the anatomical condition was meagre. I shall not refer further to this interesting point, as Dr. Legg has dealt with it very fully in a recent lecture at this College.[8] I may observe, however, that the atheromatous ulceration is also a frequent cause of aneurysm of the valves.

It was Sir James Paget,[9] I think, who first referred to the frequency with which sclerotic and malformed valves are attacked by acute disease. Chronic valvulitis is met with in a large number of cases of malignant endocarditis. The records which I have examined give only a percentage of about twenty-five, but the condition of the valves, except as regards ulceration, was often omitted, and this represents a very much smaller percentage than actually occurs. In more than three-fourths of the Montreal cases sclerotic changes were present, and Dr. Goodhart found[10] in a series of sixty-nine cases that sixty-one presented old thickening of the valves. In very many of the cases the condition of fusion of two of the aortic cusps was present. This abnormality is almost invariably accompanied by sclerotic changes, and to the existence of these is probably due the frequency with which they are attacked by ulceration. In seventeen instances of fusion of two of the aortic cusps of which I have notes there were ulcerative changes in eight, in two or three of an atheromatous nature.

In a few instances the aorta is involved with the heart. The most frequent site is the sinuses of Valsalva, the vegetations growing through the segments spread on to the aortic wall, or it is affected by friction. It is rare for the vegetations to extend into the arch. I have met with one remarkable instance of ulcerative endocarditis in which there was also ulcerative endarteritis, involving the arch and producing multiple aneurysms. The specimen which I here demonstrate was taken from a man aged about thirty, who had been the subject of syphilis and was known to have had aortic incompetency for some time. He was admitted to the General Hospital, Montreal, on June 4th, 1880, with diarrhœa, chills, headache, cough, and fever. Temperature 104°. There were signs of pneumonia at the left base. He became delirious, a low typhoid condition supervened with chills at intervals, and death took place on July 1st. The aortic valves were curled and hard, and presented extensive recent vegetations, the arch of the aorta presented four aneurysms, three small, not larger than cherries, and one the size of a billiard ball. The small ones were not noticeable as aneurysms from the internal surface, but presented the appearance of fresh fungous vegetations, on separating which little slits could be seen leading to saccular dilatations of the middle and outer coats. The large aneurysm was thin-walled with no laminated fibrine, and presented at the edges of the orifice and over the whole lining membrane of the sac many greyish-green vegetations, some of which had perforated the sac and caused a rupture into the pericardium. It may be presumed that in this instance the ulcerations led directly to the production of the aneurysms, certainly in the case of the smaller ones; and the larger sac presented a condition of mycotic endarteritis unique in my experience of aortic aneurysms.

Of associated pathological changes we have, in the first place, those connected with some primary disease, to which the endocarditis is in the majority of cases secondary. Thus, in the endocarditis of septic processes there is the local lesion, a suppurating wound, a phlegmonous inflammation, or puerperal processes of a septic nature. In a very considerable proportion of cases there is evidence of recent pneumonia, in others rheumatic affections of joints, and in a few diphtheritic processes. In the group of primary cases the lesions are entirely those of endocarditis, local and general. In the second place, there are the extensive pathological changes due to embolism, and these constitute interesting features in the disease, and may produce a very great variety of lesions in every portion of the body. I do not propose to deal very fully with these, but to call attention only to some special points. The cases may be divided into those without any embolic processes, cases in which the infarcts are simple, not suppurative, those in which there are innumerable suppurative infarcts, and cases in which some of the infarcts are simple and some suppurative. It is remarkable how variable these embolic features are. They may be entirely absent in well-marked malignant cases. They are not necessarily associated with suppuration; indeed, in a very considerable number of cases they present the characters of ordinary hæmorrhagic infarcts, but in the traumatic and puerperal cases the infarcts are invariably septic. They may be few in number, only one or two perhaps in the spleen or kidney, or they may be in thousands throughout the various organs of the body. When suppurative, micrococci, in my experience, are always present; but the micrococci may exist in the vessels without inducing this change. In severe forms of the disease hæmorrhages are very frequent upon the skin, serous and mucous surfaces. The cutaneous ones will be referred to again in connexion with the symptomatology. They appear, in many instances, to be due to the effect of the poison, just as in other infectious diseases; in others they are undoubtedly embolic, and a minute necrotic or suppurative centre can sometimes be seen. In the membranes of the brain I have twice met with extensive superficial extravasation. Litten[11] has called attention to the frequency of retinal hæmorrhages, particularly in the endocarditis of puerperal sepsis. In some instances, there are innumerable miliary

[11] Charité Annalen, iii., Berlin.

abscesses, more particularly in the heart and kidneys. They are often associated with hæmorrhage, and the smaller ones look like little extravasations, but the presence of micrococci and suppuration can be easily determined in stained sections. The spleen is most often the seat of infarction, and next in order the kidneys. The lungs are usually affected when the endocarditis is on the right side, and there may be suppuration or even extensive gangrene, but even with destructive lesions of the pulmonary valves there may be no suppurative infarcts in the lungs, as in a case of Dr. Church.[12] Or again, as in a case of Dr. Moxon's,[13] there may be with aortic valvulitis suppurative infarcts in the lungs, and simple ones in the other organs. The gastro-intestinal canal may present very remarkable changes, due to the presence of numerous infarctions, from the size of a pin's head to a split pea. They are slightly elevated, greyish-yellow in colour, often surrounded by a zone of deep congestion or extravasation, and on section may show a suppurative centre. Micrococci are present as in other miliary abscesses, and in several instances I was able to find small embolic plugs in the arteries of the submucosa. The abscesses may discharge and leave a small ulcerated surface. In the stomach there may be similar minute infarcts, and occasionally larger ones. Carrington[14] has described a remarkable case in which there was a gastric ulcer, apparently due to embolic process, in a case of severe endocarditis; and Magill,[15] a case in which the stomach was intensely inflamed, the mucous membrane at the greater curvature being black, almost gangrenous. The liver may present minute abscesses, and in a number of cases in which there has been jaundice degeneration of the cells has been observed.[16] The serous surfaces are often inflamed, pleurisy and pericarditis being not uncommon complications. The pericardium is most frequently affected in rheumatic cases in which endocarditis and pericarditis may occur simultaneously. Pleurisy is met with chiefly in connexion with the traumatic and puerperal cases, and also with pneumonia, which, as I shall show, plays such an important part in the history of this form of endocarditis. The cerebral lesions are of the substance and of the membranes. Embolic softening, simple or suppurative, is extremely common, and in very many cases head symptoms supervene and there is paralysis of one side or the other. There may be a single embolus, producing extensive suppuration or red softening, or there may be multiple infarcts in various regions.

The meningeal complications of endocarditis have not received much attention. Considering the frequency with which it has occurred in the Montreal cases, five instances out of twenty-three, I was quite prepared to find such a large number as twenty-five cases—i.e., somewhat over 12 per cent. In the majority of these cases it occurred in connexion with pneumonia. It is almost always cortical, but many extend to the base and involve the nerves, leading in one case, which I saw with Dr. Ross at the Montreal Hospital, to strabismus, and also to ulceration of the cornea from involvement of the fifth nerve. In rare instances the spinal meninges are involved, and the clinical picture may be that of an acute cerebro-spinal meningitis.[17] Acute suppurative parotitis was noted in three cases.

THE DIET OF THE FEBRILE STATE.[1]

BY W. H. ALLCHIN, M.B., F.R.C.P.,
PHYSICIAN TO THE WESTMINSTER HOSPITAL.

THE search for a perfect diet has been an object of solicitude and study from the earliest times, to the physician and the quack, to the learned and the empiric. From the resulting mass of crude suggestion and ignorant assertion it may not be said that we have gained no positive knowledge, but we should still be far from stating that the principles of dietetics have been reduced to a certainty. To the already vast literature of this subject, the dietetics of health, I have no present intention of adding, but I propose to direct attention to the question of the fitting diet for the febrile state, a morbid condition of the body which is of the commonest occurrence, and which, as affecting the system generally, may be placed in contrast to that other general state of body we denominate "health."

The problem to the solution of which I am desirous of contributing is that we should aim as far as possible at formulating some general scheme for a febrile diet, to be modified as special cases—e.g., enteric fever—may demand, just as the usual diet of health is modified in certain persons. Clearly, to lay down such a scheme, the principles of a normal diet no less than the nature of the febrile state should be first considered.

Regarding the diet of the healthy state, though much still remains *sub judice*, the profession has succeeded in ascertaining a very definite and useful series of data, that we are accustomed, and I believe with good reason, to accept as true. The one that mainly concerns us is that the essentials of a healthy diet must correspond with the component materials of the body, or, in other words, that the alimentary principles of food must correspond with the proximate principles of the human tissues; and further, that, speaking generally, they should be combined in the following proportions:—

Proteids	4½ ounces	Free from water.
Hydrocarbons ...	3 "	
Carbohydrates ...	14 "	
Salts	1 "	
Water	100 fluid ounces.	

That is to say, for an average adult with average exercise of mind and body. We have further learned that we cannot sacrifice *one* of these substances without doing harm; all must be present, and though of course it would be practically impossible to maintain existence on these crude principles, they nevertheless are the important essential components of the various articles of diet that form the food of mankind. Since no single article of diet contains the necessary alimentary principles in the proportions required for an adult, they have to be distributed among the various food stuffs in such a way as to furnish the desired amount. Doubtless we are in the habit of exceeding the absolutely necessary quantity, and the effect and destination of our surplus ingesta is a question of the greatest interest, both in health and disease, though apart somewhat from the present subject. It is further significant that a monotonous adherence to a diet, however complete, is insupportable, and results in starvation, though some articles of food are capable of being longer tolerated than others. It is interesting and pertinent to the question to note how these data were arrived at. The quantity and quality of the alimentary principles may be said to have been determined partly by the experience of mankind based upon instinct, but more recently by the accurate methods of tissue analysis, which demonstrates the structures which have to be repaired, and the excreta analysis, which equally shows what has to be supplied to make good the deficit and maintain the balance. I shall have occasion to consider how these methods are further applicable, or indeed have been applied to the subject in hand. But, however exact we may in time come to be in our results, however accurately we may demonstrate the nature and source of the excreta, and thence with equal certainty define the requisite ingesta, there will still remain a factor with which we must cope, and which has been termed "idiosyncrasy." There can be no doubt that a very considerable difference exists between what may be termed a theoretically perfect diet and the diet which best suits a given individual; and I think Dr. Austin Flint has done good service in drawing attention to the harm that may be done from a too rigid adherence to a presumed scientific dietary based on chemical analysis, to the exclusion of what appetite, experience, both personal and general, and common sense would dictate.

A further consideration preliminary to my subject is the destination of such a diet as I have mentioned; in short, the need for the food, or the object of its ingestion. That the energies manifested by a living being are the resultant of an alteration in the physico-chemical condition of some of the materials of its structure is now regarded as an axiom; and it necessarily follows therefore that, if the manifestation continue, the material, to changes in which it is due, must be as continually renewed. Hence, we are in the habit of saying that our need for food is to repair the tissue consumed in the production of living energy. The distinctive forms of energy that characterise living beings, and that in

our present state of knowledge are not regarded as correlated to the physical forms of force, however much they may come to be shown to be but "modes of motion," are muscular force or contractility, nervous irritability, and gland force. An arrangement of tissues and organs that liberates these is undoubtedly living and probably an animal. But be it observed that in addition to these, heat and electricity are evolved at the same time, and these are precisely identical in nature with the same named forces that we can develop from non-living material. The exact relationship of animal heat to the producing organism needs to be set forth. It is well-known that the tissue metabolism underlying the manifestation of the vital energies above mentioned is invariably accompanied by a rise of temperature; the contractions of the muscles are associated with heat production, the secretion of glands the same to a less extent, the activity of nervous tissue to a still less degree, and an infinitely small amount of heat is liberated by the slight changes in the protoplasmic constituents of the connective tissues. Observations and analysis have shown that muscular contractility, and almost as certainly nervous energy, are not produced at the expense of the actual nitrogenous constituents of muscle and nerve cell, since the resulting nitrogenous waste is not proportioned to the work done; but in all probability they are due to the oxidation of some hydrocarbon material intimately involved and incorporated with the protoplasmic substance, the latter suffering a wear and tear (also in the nature of oxidation) comparable to that of the bars of a furnace, the fuel contents of which are the actual source of the heat produced. In accordance with this view the oxidation of the hydrocarbon included in the muscular fibre results in the liberation of a form of energy which, under the influence of the complex, unstable, nitrogenous protoplasm, is translated into what we call "muscular contractility;" but at the same time there is evolved a certain amount of heat, also due to the oxidation of the same material. The heat, then, is an accompaniment, or bye-product, of the same process, and may be produced at the expense of so much muscular energy, just as in mechanical arrangements heat is developed by friction in the operation of the various parts, often at a positive detriment to the total result, and certainly not being the object for which the machine is worked. The other aspect of the relationship of the animal heat to the body is that for the manifestation of the activities of the living tissues a certain temperature is necessary, since many chemical decompositions will only take place under the influence of heat. This obviously is, if I may so say, the necessity for the body temperature, and the question at once arises whether the total quantity of heat requisite for this purpose is derived from the metabolism of muscular, glandular, and nervous tissue (including therein the extremely small increment derived from the oxidation of the protoplasmic structure); or whether there be any special combustion of certain of the ingesta for heat-production only, and if so where may this take place? The general opinion would seem to be that the heat under conditions of health is derived entirely from the tissue disintegration accompanying the liberation of the specific vital energies. There is not much doubt that the destination of the various fat, sugar, and starch ingesta is to maintain the supply of the hydrocarbon material by the oxidation of which the living energies and the heat of the body are produced. There is good reason to suppose that the carbohydrates ultimately reach the site of their combustion as hydrocarbons, although the exact chemical steps of the conversion are as yet unknown. Nor are these thought to be the sole sources of the fuel. It is very generally believed that only a small portion of the total nitrogenous ingesta is ultimately concerned in the restitution of the protoplasmic waste; in fact, that far more proteid material is taken as food than is actually required to make good the proteid decomposition, although on grounds of experience, and for other reasons, such an amount as that above stated is found most suitable. The excess of such substances in all probability undergoes a decomposition, perhaps in the liver, which results in the formation of some carbohydrate (glycogen) or fat, leaving a nitrogenous residue akin to urea, which is excreted, the other directly or indirectly helping to furnish that hydrocarbon which is oxidised in association with the living tissue. Among the many interesting questions which surround this part of the subject, I might mention the value of the nitrogenous ingesta apart from their constructive function, as seen in the influence they exert over fat accumulation, and the exceedingly important inquiry as to the existence and conditions of the "reserve pabulum." With such a conception of the relation of the energies produced to the tissues of the body, it only remains for me say that calculated upon the waste resulting from the disintegration of these tissues, as excreted by kidneys, lungs, skin, and bowels, is the quantity and quality of the diet that experience also shows is most consistent with a healthy existence.

Turning now to the state of fever, although we must admit our knowledge of its intimate pathology to be deficient, we are nevertheless in a position to affirm that it is a general morbid state characterised by a marked perversion of function, and associated with an equally marked alteration in the quality and quantity of the excreta, itself a material index of abnormal tissue change, the actual existence of which within certain limits the microscope reveals to us. The most prominent and obvious functional perversion is an elevation of temperature, and I think it worthy of notice that whilst this, the most characteristic feature, is excessive production of a by no means peculiarly vital force, but on the contrary of the most widespread form of energy known to us, those more distinctly characteristic features of living tissue—contractility, nervous irritability, and gland force—are all diminished in their manifestation. The muscular power of the febrile patient is deficient, his nervous energy is impaired, and the secretions are diminished. Whatever doubts one may entertain as to the seat of origin of pyrexia, whether the fever consists in disorder of the nervous centres whereby there is a diminished loss of heat from the body, with a consequent retention, and so elevation of temperature, or whether the process commences in the protoplasmic tissues generally, and only secondarily brings about the systematic disturbances, the broad fact remains that there is an undue consumption of material. We recognise this in the wasting and loss of body weight; adipose tissue, muscles, and even the bones suffer. Nor is the evidence of loss confined merely to gross alterations that may be measured by the scales. Analysis of the excreta shows the extensive disintegration of tissue that accompanies the pyrexia, and at the same time indicating the proximate principles of the tissues, the combustion of which liberates the heat, suggests the food that is demanded for their supply, just as we infer the materials of a normal diet from the nature of the excreta in health.

There is a general agreement that the nitrogenous waste represented by urea, which is the most important (although equally true of uric acid and creatinin), is considerably increased, commencing even before the elevation of temperature and continuing throughout the whole febrile course. In so much as we shall see it is only in rare cases that the febrile state is not accompanied by a diminished nitrogenous ingesta, it must follow that the urea excreted must be drawn from the proteid tissues of the body, which undergo a more extensive disintegration than in health, and this should be remembered in reference to those cases where the total nitrogenous waste is absolutely less than that of health with ordinary diet, but is absolutely greater when the same healthy person is put upon a fever diet, which is invariably deficient in proteid alimentary principles. Respecting the amount of CO_2 in fever, much difference of opinion exists. The experiments of Senator on dogs would at least render it doubtful whether there be an increased formation of it, though there may be an increased elimination, since in fever such circumstances as quickened respiration are favourable to excretion; but the observations of Leyden on febrile patients would seem to show that there is an excessive formation. It is noteworthy, however, that there is by no means the marked considerable excess as is the case with urea, and also with water, which is largely increased in the amount lost (not by the urine, where it is diminished, but) by the skin and lungs. Indeed, the loss of body weight is mainly to be attributed to the loss of water. The elimination of salts in fever affects chiefly those of potash, which are excreted in far greater abundance than in health, even to sevenfold; whilst those of soda are, on the contrary, much diminished in amount, and may even be suppressed. Concerning the acids, whilst hydrochloric acid is certainly diminished, phosphoric and sulphuric acids would seem not to be increased. The urinary pigments are largely increased in amount. Of the hydrocarbons usually excreted in the fæces and by the skin, nothing is known in the febrile state. From such general conclusions as to the excreta of the pyrexial condition, conclusions which I have

not attempted to express in figures, we gather that whilst the increased excretion of water may be regarded as a withdrawal of that fluid from the tissues generally, and is but very partially the result of tissue metamorphosis, it is the nitrogenous tissues of the body that give the most positive evidence of excessive disintregation; the increased elimination of urea and uric acid and of potash salts unmistakably indicates an excessive wear and tear of the protoplasmic tissues of the body, nerve, muscle, and gland, as well as the blood-corpuscles. Remembering, as we have seen, that the main source of heat in health is the oxidation of hydrocarbon material, which is intimately associated with the protoplasm, and that only a very small increment of the total quantity of heat produced is derived from the oxidation of the machine itself, it would seem at first sight that in fever we have a reversal of the process, and that we are in face of an excessive oxidation of the nitrogenous material of the tissues ("tissue albumen" of Voit), as indicated by the excreta, whilst the hydrocarbon suffers but little if any increased consumption—that is, if we are justified in estimating the CO_2 formation as being but slightly increased, this gas being one of the chief products of hydrocarbon combustion. In this way we might be inclined to expect the nitrogenous excreta would be a measure of the heat production; were that so, the maximum temperature should coincide with the period of greatest nitrogen formation, and both should correspond. But it is doubtful if this be so, for preceding the period of elevation of temperature the urea excreted is in excess of normal, and the same excess continues for some time after the defervescence. The latter may be in part explained by the continued removal of what had been produced in the body during the period of fever, but this will not account for the prefebrile excess. If, then, in fever we are to base the quality and quantity of our ingesta upon the character of the excreta, as has been done in regard to the healthy body, the nitrogenous alimentary principles should obviously be administered in excess over the normal requirements, whilst there is no very positive indication for an increase in the hydrocarbon or carbohydrate food-stuffs, or, at all events, not to anything like the same extent.

Now, let us consider how far experience, or at least practice, supports this conclusion. The dietetics of fever, like many other principles based upon insufficient data, have had their fashions, and opinion has swayed now to starving, now to feeding; we pride ourselves, perhaps, at the present day on maintaining a wise medium. I think I may be fairly stating the case if I say that a patient suffering from any febrile disease is put upon a diet consisting of two to three pints of milk, and one to two pints of beef-tea. It is worth for a moment considering what this really represents in terms of alimentary principles. Taking the milk in round numbers at fifty fluid ounces, that would contain about two ounces of proteids, the same quantity of fats, rather more of sugar, and about half an ounce of salts. In regard to the beef-tea it is well at once to recognise that as a nutriment it holds a very inferior position. Supposing the meat from which it is prepared to contain about 20 per cent. of nitrogenous matter, certainly not more than 1 to 1½ per cent. of the proteids will be extracted by any ordinary process of cooking, but with them there will be as much again, or even more, of the meat extractives, such as creatin, creatinin, &c., which although nitrogenous are not nutritious (i.e., are unable to repair protoplasmic waste) and are members of the large group of bodies vaguely known as stimulants. A very variable amount of fat dependent on the quality of the meat used, and about one-half per cent. of salts, make up the 5 per cent. of solids which ordinary beef-tea contains. Such a diet therefore represents, as compared with the minimum requirements of a healthy adult in ordinary work, about half the proteids and fats, a third of the carbohydrates, and rather less than the necessary salts. This is clearly not in accordance with what we should consider to be called for in the febrile state, did we make the excreta the basis of our calculations; and yet we are accustomed to consider that such a diet is most suitable for the general disturbance of nutrition that fever indicates. Obviously, therefore, some other circumstance has to be considered, and that is the capacity for digestion exhibited by the fever patient. It is one thing to calculate on paper that such and such should be the diet, but it comes to be quite another thing when we are brought face to face with digestive organs that are as a consequence of the existing pyrexia greatly disturbed in their functional capability. The process of digestion essentially consists in effecting in the ingesta a series of changes of a physico-chemical character which shall enable them to be absorbed into the vessels. By mastication and the movements of the alimentary canal, and by the solvent and fermentative action of the various digestive juices this is brought about. Except with some gastro-intestinal lesions, fever usually tends to constipation, to be explained in part by the diminished power which the muscular coat of the bowel manifests in common with the muscular system generally. It is rarely, however, that this becomes a serious symptom. But with respect to the chemical process of digestion the case is different; here we meet with conditions which are very far from the normal. I need not mention the various parts played by the secretions of the digestive glands, or how the food-stuffs are reduced to a diffusible condition; but it is desirable briefly to consider the changes that have been recognised as taking place in these secretions when produced in a febrile state of body.

It may at once be said that observations distinctly indicate that they are all diminished in quantity—that is to say, the saliva and the gastric and pancreatic juices. The bile occupies a place apart, and of the intestinal juice in pyrexia I am not aware that any observations have been made. The secretion of saliva is so decreased that in many cases it can have practically no effect as a solvent of starch, and even when present, as shown by Mosler, it is far short of the normal juice in fermentative power, not unfrequently being of an acid reaction. Its absence also removes one of the stimuli to the secretion of the gastric juice, a secondary effect that it is regarded as producing when swallowed into the stomach. The recent experiments of Eringer (1882) do not confirm those of Manassein (1871), which went to show that the acid of the gastric juice is markedly deficient in fever. The former observer, however, asserts the contrary to be the case. But whichever be the truth, the digestive power of the secretion as a whole is far inferior to that of the healthy state; and owing to irregular decomposition induced in the ingesta, decompositions which tend to a putrefactive character rather than to the formation of normal peptones, certain irritant materials are liberated, to which I believe in great part may be attributed the gastritis so frequently accompanying the condition of fever. The pancreatic juice has been made the subject of special study by Dr. Stolinkow,[2] who by establishing a pancreatic fistula in a dog ascertained the characters of the normal secretion, which he compared with the juice after inducing fever in the animal. A temporary increase both of the fluid and its ferments occurred at first, soon followed, however, by a more prolonged decrease in amount, and impaired proteolytic and amylolytic power. Even admitting that our knowledge of the nature of the digestive juices in fever is very deficient, enough is known to justify the assertion that their capability in one direction or another is seriously deteriorated, affording thereby an opportunity for the formation of decomposition products, many of which are of a most noxious character. The obvious indications under such circumstances are to give aliment that requires the minimum digestion, to prevent as far as possible the delay of the food in the gastro-intestinal tract, and supplementing where we can the deficiencies of the secretions by artificially prepared ferments, acids, and alkalies. Heat, as we have seen, is one of the force manifestations of tissue change, as urea, carbonic acid, and water are some of the material expressions of the same. In fever the heat, the tissue changes, and the excreta are all increased. The demand for increased food is therefore obvious, provided it can be digested or can be administered in such a diffusible form as to require but little digestive change. With secretions that have suffered such considerable alterations as I have described, the digestion of the ordinary articles of diet is impossible, and experience dictates a departure from the usual meals.

I have already criticised what may be called a typical fever diet of milk and beef-tea, and a reference to the general rules laid down and followed by those who are entitled to speak with authority on these points shows a remarkably large proportion of the proteid alimentary principles in the permitted diet relatively to the fats and starches. Such would be quite in accordance with the indications afforded by the excreta, as I have shown; but I rather think the real ground for such exclusion of hydrocarbon and carbohydrate principles (materials which, be it observed, form by far the greatest proportion of the solid

[2] Virch. Archiv, 1882.

ingesta in a normal diet) is a widespread belief in the incapacity for their digestion by the febrile patient, and the injurious effect of the lactic and butyric acid fermentations that take place in the stomach from the improper fermentation of the amyloids. Some writers are very emphatic on this point, and doubtless with good reason. Quite recently the experiments of Dr. Tchernoff have demonstrated that there is an average of 7·2 per cent. less absorption of fats in a fever patient than in the same person in health, when from 80 to 90 per cent. of that ingested obtains entrance into the vessels, a marked exception to this occurring in the case of enteric fever, where the large increase of leucocytes in the mucosa is regarded as effecting an increased transfer of fat granules from the epithelial surface into the lacteals. But if these fats and starches are to be forbidden, and still more if the heat products of pyrexia be but slightly due to their combustion, one can see good reason for the larger relative share that nitrogenous material should take in the total aliment. But, notwithstanding this, I am doubtful whether there is not a flaw somewhere in the reasoning, and am justified by no less an authority than the late Dr. Parkes, who, in his memorable Croonian lectures on the Elimination of Nitrogen in 1871, spoke on this point as follows:—"Can we foretell from our present knowledge of the chemistry of fever what should be the treatment by diet? I do not think our knowledge is sufficiently precise for this, and practice alone can rightly guide us. Still, some suggestions present themselves. There is in fever a waste of albuminous tissues; it would, therefore, at first sight appear an indication to feed those tissues with nitrogenous food. But it may be questioned whether they can be fed. Some of Huppert's observations indicate that they cannot be, and that the nitrogen is eliminated without being used by the wasting parts. And if so, what becomes of the albuminous food? It must be disposed of by the the glandular elements, and add to the work already thrown on those organs. May it not be that, in the height of pyrexia, partial abstinence from nitrogen should be the rule, while the succeeding period of apyrexia is that in which it should be given, when the body retains it, and thus makes up the standard it had lost?" Continuing, the same writer expresses a belief, founded on experience, "that the almost exclusively animal diet sometimes given in fevers is not so useful in sustaining the strength as is supposed, and that if it were not for the loss of appetite which limits the supply, we should perceive more clearly the bad effects," and he has thought that "the vast deposit of urates which sometimes marks the end of fevers might be really caused by excessive animal food," and that he has actually seen "gouty attacks brought on by that system of feeding." Referring to fats and carbohydrates, Dr. Parkes observed "a supply of fat to meet the disappearance of the same from the body is rarely attempted in practice, and yet there is no doubt that if digestible fats are given to fever patients the degree of emaciation is much less, and at the end of the fever the body seems more speedily to recover itself. The fats are often considered hurtful, and are sometimes excluded from fever diets, so that with the large supply of animal food, the patients are brought almost into a state of Bantingism. The starches and sugars are generally given in fevers, and it cannot be doubted that this is right, though probably the amount given is usually far too small. An eminent physician desired for his epitaph the words, 'He fed fevers.' His pride in his treatment was legitimate; but it may be still a question with what they should be fed."

I do not know that we can honestly say we have reached a point much beyond this, even after the lapse of fourteen years: our knowledge is "not yet precise enough," and I am not sure that practice has guided us very far, it having preferred to pursue the old track without much question. I cannot help thinking that the strong objection held to the administration of amyloid food in fever is exaggerated. I am in the habit of insisting upon a fair share of it in the treatment of my patients, and I have not yet seen reason to attribute any ill effects to the proceeding. In the artificially digested foods that we have at our disposal now, I believe we possess alimentary principles that, in the form of partially digested proteids and amyloids, are quickly absorbed, and hence diminish the opportunities for butyric and allied fermentation, and also make less demand upon the digestive secretions. It cannot be too carefully remembered that one object to be aimed at in laying down a diet for fever is to prevent delay of the ingesta in the alimentary canal. Even the blandest and most nutritious aliment may become a source of noxious decomposition product when acted upon by juices secreted in the pyrexial state, but in reference to this the question of absorption has to be taken into account, and of the effect of fever on that I have no knowledge beyond what I have said respecting fats.

I think I need not further urge the importance of this subject, for clearly to know how to sustain our febrile patients, and, what is of equal consequence, to shorten thereby their period of convalescence, during which the tissues are getting back into their normal condition, would be of extreme value, and although exact information on many of these questions is still wanting, I have endeavoured without seeking to be original, though perhaps suggestive, to give a brief and coherent account of the state of existing views, to indicate what we know and what we do not, to formulate our ignorance no less than our knowledge, and to offer thereby the opportunity for a rational plan of further inquiry.

ONE HUNDRED AND ELEVEN CASES OF LITHOLAPAXY.

BY P. J. FREYER, M.A., M.D., M.CH.,
SURGEON, H.M.'S BENGAL ARMY; CIVIL SURGEON, BAREILLY, N.-W. PROVINCES.

(*Continued from page 378.*)

CASE 24.—A Mahomedan male, aged forty-eight, was admitted on Jan. 9th, 1883, with retention of urine which had existed thirty-six hours. He had suffered from symptoms of stone for nine months, being much exhausted, with pinched, anxious expression. On passing a full-sized catheter a small calculus was detected at the neck of the bladder, blocking up the urethral passage. This was pushed back with some force and the retention of urine relieved. The patient was at once anæsthetised and litholapaxy performed. The operation lasted only eight minutes; the débris weighed twenty grains.—10th: Passed very little urine since yesterday. Pain in region of the bladder. Catheter passed and a small quantity of urine drawn off. Hot fomentations and hot poultices to the hypogastrium were ordered; also one grain of opium internally every three hours. — 11th: Well-marked peritonitis present. Temperature 102° F.; respiration 44 per minute; urine scanty. The catheter was used twice daily.—13th: No pain. Great distension of abdomen; patient very weak; passing a little urine. He died quietly in the evening.

Post-mortem examination. — On opening the abdominal cavity it was found distended with clear serous fluid. The bladder was embedded in a mass of amber-coloured gelatinous lymph, which broke like cold jelly on application of the fingers; congestion of the cellular tissue at the base and neck of the bladder; mucous membrane of the urethra near the neck of the bladder highly inflamed; no congestion of the bladder or kidneys.

CASE 44.—A Hindoo, aged forty-five, was admitted on May 23rd, 1883, with symptoms of stone, the most prominent of which were agonising pain in the region of the bladder and passing of blood and pus in the urine. The symptoms had existed eight years, and the patient was in a very weak state. A large calculus was detected by the sound. On the 25th I performed litholapaxy. Considerable difficulty was experienced owing to the large size and hardness of the calculus, and the operation progressed very slowly, fourteen drachms being removed in seventy-five minutes. No more fragments could be felt by the lithotrite, but on passing the sound a large fragment was detected high up at the fundus of the bladder. As the patient was very much exhausted, I was afraid to keep him longer under chloroform, so I had unwillingly to postpone the completion of the operation to another day.—24th: He had great pain in the region of the bladder the whole of yesterday, which was controlled by one grain of opium administered every three hours. Urine scanty and blood-stained. Temperature 104° F.; great thirst. Fever mixture ordered and opium continued.—27th: Had a severe rigor last night; fever continued all night; patient anxious and depressed. Ten grains of quinine were ordered, and to be repeated in the evening. No pain in the abdomen, but great pain in the left hip.—28th: Abscess forming in the

left hip. All the symptoms of blood-poisoning present. Carbonate of ammonia and bark mixture ordered. The patient died at 10 P.M.

Post-mortem examination.—The walls of the bladder were greatly thickened, sacculated, and contracted; in the bladder were a large fragment of calculus (about one ounce in weight) in a sacculum at the fundus, several small patches of inflammation of the mucous membrane in the vicinity of the fragment of stone, and some milky urine. The tissues of the left gluteal region and round the left hip-joint were swollen and infiltrated with dark-red fluid. Cause of death pyæmia.

CASE 97.—A Mahomedan male, aged twenty-six, was admitted into the Bareilly Civil Hospital on August 12th, 1884, suffering from the usual symptoms of stone, which had existed six years. During the last three years the symptoms became much aggravated. On admission micturition was extremely painful and difficult, and the urine was mixed with pus and blood. The patient was in extremely bad health; very thin and anæmic; scarcely able to stand. On August 14th I performed litholapaxy. Chloroform was given by Dr. Corbett, Royal Medical Service, by means of Junker's inhaler. The calculus was a large hard one, weighing three ounces and a drachm a half, and consisted of oxalate of lime. The operation lasted fifty-two minutes. After slitting the floor of the meatus slightly a large lithotrite was passed, but, owing to the contraction of the walls of the bladder on the stone, it could not be grasped. The lithotrite was withdrawn and four or five ounces of water injected by the aspirator, and then the calculus was easily grasped after a little manipulation. I had to use all the force I was capable of before the stone gave way. The fragments were then disposed of one by one, great force being necessary in dealing with even the smallest fragment. The lithotrite had to be introduced six or seven times, and the evacuator as often, before the whole of the calculus was disposed of. My new large lithotrite did great execution amongst the fragments, the glass receiver of the aspirator being nearly filled each time after withdrawal of the lithotrite. Two or three times during the operation the patient was very faint and almost ceased breathing, and after the operation the pulse was extremely weak. Artificial breathing had to be maintained, occasionally, for an hour after the operation. Evening: Passed urine freely during the day, the earlier portions were blood-stained, the later clear; no sand or fragments passed; no pain in the bladder, but tenderness along the course of the urethra. Pulse 90 (very weak).—15th: Patient very weak; passed three loose stools during the night; urine passing freely, and quite clear; vomited twice this morning; pulse almost imperceptible; hands and feet cold; drowsy and restless; wanders in his conversation at times. During the course of the day the patient revived a little, but he grew weaker towards evening, and died at 9 P.M.

Post-mortem examination.—Bladder empty (not a trace of sand was present), contracted, and its walls much thickened; mucous coat was corrugated and slightly sacculated; urethra congested along its whole length; ureters dilated along their whole length, so that the tip of the little finger could be passed into them from the bladder; kidneys extensively diseased; the calyces were much dilated, and the medullary portions had almost disappeared; the cortical portions were hard and pale; pericardium distended with clear straw-coloured fluid.

The patient in Case 7 was almost moribund on admission to hospital. There was complete atony of the bladder, and the condition of the mucous membrane of the bladder may be imagined from the fetid state of the urine. The man was so weak and exhausted that I could not entertain the idea of performing lithotomy, so I gave him the only prospect of recovery in performing litholapaxy. In Case 24 death resulted from peritonitis, evidently produced by extension of inflammation from the neck of the bladder. It is difficult to say if this was due to the operation or to impaction of the calculus at the neck of the bladder, and the force necessary to displace it. I am inclined to think the latter was the cause. There was no difficulty whatever in performing the operation; the stone was very small, and the operation lasted only eight minutes. The bladder was healthy except at the neck, where the calculus had lain impacted for two days. The kidneys also were healthy. It is probable that the calculus, forced on by the accumulation of urine and efforts at micturition, acted as an irritant to the mucous membrane, and that the force necessary to push back the stone into the bladder increased the irritation, thereby producing inflammation. In Case 44 the cause of death was pyæmia, the result of cystitis supervening on the operation, and caused by the irritation of a large fragment, which it was found impossible to dispose of at the first sitting, owing to the exhausted state of the patient. Death in Case 97 resulted apparently from the shock of the operation and exhaustion produced by the chloroform, acting on a constitution worn out by the painful nature of the malady and extensive disease of the bladder, ureters, and kidneys. Emboldened by having previously removed a larger calculus successfully in Case 16—the details of which will subsequently appear—and by a long-continued series of successful cases, from Case 45 to Case 96 inclusive, in many of them the calculi being very large, I had no hesitation in attacking the stone in this case, and I feel confident the patient would have recovered but for the extensive disease of the kidneys which existed, and from which the patient must have succumbed to any operation. The large and powerful lithotrite sent me lately by Weiss worked admirably in this case. The manner in which a large oxalate of lime calculus, weighing over three ounces, and as hard as flint, was crushed to atoms and completely removed by the aspirator in fifty-two minutes, without the necessity of any dilatation of the urethra or injury to the urinary passage, shows what can be done by the new operation. Though the crushing power of this instrument is very great and the strength of the steel enormous, it was noticed both by the surgeons who honoured me with their presence during the operation and by myself that when dealing with a large and hard stone of this kind the leverage in the instrument is deficient. This might be easily remedied by having long knobs to the wheel-shaped handle of the male blade, and by the addition of a light crossbar to the cylindrical handle of the female blade, both the knobs and crossbar being removable, so that they might be applied only when large calculi are dealt with. With the exception of the four deaths above referred to all the cases made excellent recoveries. Cystitis, which so frequently followed on the old operation of lithotrity, and which often left the patients in almost as bad a condition as they were before the operation, seldom occurs after litholapaxy; and when it does occur, or had existed previous to the operation, it is very amenable to treatment.

The 111 operations were performed on 109 different individuals, the disease having only twice recurred. In one of these cases the patient, aged sixty-five, was suffering from enlargement of the prostate. Six months after the first operation, in which four drachms of a soft phosphatic calculus were removed, he returned and had a similar calculus weighing eighty-five grains removed. In old patients of this kind, with enlarged prostate, the disease frequently recurs, owing to the fact that the bladder is never completely emptied of urine during micturition. In the other case several small calculi, varying in size from that of a pea to that of an almond, and weighing in all one ounce, were removed, and the patient left the hospital quite well. A month afterwards he returned with symptoms of stone. At first I imagined that a fragment had been left behind at the first operation, but on applying the cannula and aspirator I removed twenty-seven minute calculi, weighing half a drachm in all. I then found that in the interval the patient had suffered from severe kidney colic, and that the minute calculi, each of which consisted of a uric-acid nucleus with phosphatic deposit, were the result of a shower of uric-acid particles from the kidney. The calculi removed varied in weight from five grains to three and a quarter ounces. There were fifty weighing half an ounce and upwards, twenty-seven one ounce and more, seven two ounces and upwards, and two over three ounces. The following are the details of the case in which the largest stone was removed, to which I wish to call especial attention:—

CASE 16.—Illaki Buksh, a Mahomedan aged sixty, was admitted into the Moradabad Civil Hospital on Dec. 3rd, 1882, with all the symptoms of stone in the bladder, which had existed eleven years. On admission the patient could only pass urine in drops continuously throughout the day and night, and the passage of urine was attended with great pain. His penis and foreskin were hypertrophied from the patient's constantly rubbing the organ to relieve the pain and irritation. A urethral calculus was felt in the fossa navicularis. When the patient tried to pass urine he had to rub and pull the penis, and in this way push the urine past the calculus in the urethra. The urine was mixed with pus and blood. The fæces passed were ribbon-shaped, due to pressure of the stone in the rectum. On passing the

finger into the rectum a large stone could be felt in the bladder. The patient's health was very bad. He was pale, thin, weak, and anæmic, and he had a pinched, anxious expression, the result of long suffering. On Dec. 5th I performed litholapaxy, the urethral calculus having first been removed after slitting the floor of the urethra slightly. The operation lasted sixty-six minutes, and the débris weighed three ounces and a quarter, the calculus being a hard uric-acid one. Considerable trouble was first experienced in grasping the stone, owing to the contraction of the walls of the bladder on it. This was obviated by injecting water into the bladder. The lithotrite was introduced at least a dozen times, and after each crushing a large quantity of débris was washed out through a No. 18 cannula. With the exception of slight pain in micturition during the first day or two the patient had no after-trouble. He made a rapid recovery, and on Dec. 15th, when discharged from the hospital, the following entry in my note-book describes his condition:—"Patient now rid of all bladder symptoms. Urine quite clear; bladder retains a large quantity at a time. Has grown fat and strong. Says he has not been so well for several years. This man was a miserable creature on admission to hospital ten days ago, and now leaves it in excellent health." This is, as far as I am aware, the largest calculus that has ever been removed from the bladder by the crushing operation at one sitting. The amount of manual labour required in crushing a large and hard stone of this kind is something excessive. I felt completely exhausted after the operation. My hands were blistered from the *lithotrite*, and the muscles of my arms ached for two or three days subsequently. I cannot too strongly advocate the desirability of removing the whole of the calculus at one *sitting*. This is the essential principle of the operation. This fact seems to be lost sight of by some surgeons, for I have noticed that in some of their recorded cases a second, and even third, operation was necessary. An operation prolonged over several sittings in this way involves all the dangers of the old operation of lithotrity and ceases to be litholapaxy in my acceptation of the term. Male patients of all ages, from sixteen to ninety-six years, were operated on. The average age was forty-seven years and a half. Several patients of eighty years and over had large calculi removed successfully; and in one case I removed a hard uric-acid stone weighing nine drachms and a half from a patient aged ninety-six, the operation lasting one hour. The details of the case are interesting, so I give them.

CASE 69.—This was a case in private practice. The patient, a Mahomedan of Moradabad, stated that he was close on 100 years of age, and by calculation he appeared to be ninety-six. He was a dried-up, withered creature, without a tooth in his head, and consisting almost of skin and bone only. Several of his sons were living, and one of them looked seventy years of age. Till about a month before coming under my treatment he had enjoyed good health, and used to walk about the bazaar daily. He was suffering from well-marked symptoms of stone, especially great pain in passing urine. He was very weak and unable to leave his bed. On October 28th, 1883, I performed litholapaxy, the débris weighing nine drachms and a half, and the operation lasting one hour. The patient made a rapid recovery and was able to walk about on November 13th. Five months afterwards I had the pleasure of showing this old gentleman to Surgeon-General W. Walker. He was then in excellent health, so much so that Dr. Walker writing of him at the time amusingly says: "He must certainly be ninety, and looks as if he might live for thirty years now, and then do service as an old rail."

My experience is that old patients bear the operation much better than young men, and in them it is less likely to be attended by urethral fever. The explanation of this is to be found, I have no doubt, in the fact that the mucous membrane of the bladder and urethra gets less sensitive as life advances, and also that the urethra is more capacious in old than in young men. In several instances very small calculi were removed. The diagnosis of such calculi by the sound is often a matter of extreme difficulty; and experience teaches us that a patient is often sent away from hospital with a stone in his bladder after an opinion to the contrary has been expressed. I cannot speak in terms of too high praise of Sir Henry Thompson's sound. Any sound will detect a large or moderate-sized stone; but when I have failed with all other sounds in detecting a small calculus, Sir Henry Thompson's sound has brought it to light. I find from experience, however, that, even with Sir Henry Thompson's sound, a small calculus lying in some peculiar position in the bladder may evade detection. In the *Indian Medical Gazette* of March last I called attention to a new method of diagnosis for small calculi by means of the aspirator. The method of employing it is indicated in Case 54.

(To be concluded.)

TWO CASES OF HYDROCELE IN THE FEMALE.

BY SAMUEL OSBORN, F.R.C.S. ENG.

HYDROCELE in the female subject is of sufficient rarity to warrant the following two cases being put on record. Both were admitted as out-patients to the Hospital for Women, Soho-square, within a few weeks of each other, and were sent to me as supposed cases of irreducible hernia. The first case is one of hydrocele of the femoral canal, and of greater rarity than the second, which is one of the canal of Nuck. The first is very similar to a case that was reported in THE LANCET on April 5th, 1879. It is, however, in a younger woman, and both are of especial interest, in showing, equally with hydrocele in the male subject, that if it is desirable to effect a permanent cure, simple tapping is not sufficient. I mean tapping and subsequently allowing the patient to return home, walking or travelling some distance to get there. I am of opinion that if, instead of treating these cases as out-patients, I had simply tapped them, manipulated the two sides of the sac by rubbing them together to set up superficial inflammation, and subsequently applied an ice-bag and kept the patients in bed, I should have succeeded in curing them at the first operation, in the same way as I was successful in the case previously reported. The diagnosis of these cases is not easy; the difficulty of examining them by transmitted light is great. An ordinary stethoscope is the best instrument to use for the purpose, but with this care must be taken, as it is very easy to direct the vision against the inner side of the tube and not directly to its opposite end. An absence of impulse on coughing, and sometimes fluctuation, are the diagnostic signs to aid us, but that of transparency by transmitted light is the only trustworthy one.

CASE 1.—Eliza W——, aged thirty, a married woman, first noticed a lump in the right thigh seven or eight weeks before she came under observation, which gradually increased in size until it became as large as an ordinary hen's egg. The tumour was exactly in the situation of a femoral hernia, for which she was sent by her medical man. It was soft, with no impulse on coughing; there was indistinct fluctuation, and, although transparent by transmitted light, it was somewhat difficult to obtain this means of diagnosis by reason of its situation. On July 9th the swelling was tapped, and a clear yellow fluid evacuated. A femoral truss was applied to keep up pressure upon the walls of the cyst, after they had been well rubbed together; and the patient returned to her home in Essex, and kept to her bed for a week. Three weeks from the date of the tapping the cyst refilled, and became the same size as at first. On Oct. 10th, the patient being in bed, the cyst was tapped, and, the walls having been thoroughly manipulated, tincture of iodine was injected. This occasioned momentarily great pain, and the cyst was allowed to empty itself of the injected fluid. An ice-bag was applied, and kept on continually for three days. Slight inflammatory swelling took place, but this soon subsided, and she got up after ten days, wearing her femoral truss; the swelling had entirely disappeared. On Dec. 4th there was no return of the swelling, and the use of the truss was discontinued.

CASE 2.—Jane P——, aged thirty-five, single, had noticed a lump in the right groin for seven years, which had gradually increased in size. She had never worn a truss, but had used a bandage, which was discontinued on account of its occasioning discomfort. The swelling was the shape and size of a large pear, with the stalk pointing downwards to the labia; it was transparent by transmitted light, with no impulse on coughing, and no alteration in size when lying down or after a night's rest. On Sept. 11th the cyst was tapped and rather more than half a pint of canary-coloured fluid withdrawn. A few movable glands were felt after the evacua-

tion of the fluid, but the cyst collapsed completely. The walls of the cyst were well manipulated by rubbing the two internal surfaces together. An ice-bag was applied for some four or five hours; and, a right scrotal truss having been applied, she was allowed to return home and ordered to keep her bed for three days. This she did, but immediately she commenced to go about the swelling returned, and became as large as ever. On Nov. 6th the patient was admitted into hospital, and, the cyst having been tapped, about forty minims of Morton's solution were injected. On the 7th she complained of much pain in the lower part of the abdomen and in the cyst. A considerable quantity of clear fluid came from the puncture during the night, soiling the linen and rendering it quite stiff. By the 9th the swelling had increased in size, being tense and red, although the pain was less. A trocar was inserted and about four ounces of clear claret-coloured fluid were evacuated. On the following day the patient felt much relieved; a considerable quantity of fluid had escaped during the night. On the 18th the cyst was nearly the same size. It was again tapped, and the fluid, which came away with difficulty, necessitated the cyst being well squeezed to thoroughly empty it. A certain portion of the swelling remained, as if partially solidified. About half a drachm of tincture of iodine was then injected, and a flannel spica bandage put on and an ice-bag. The next day the patient felt comfortable, experiencing no pain. On the 22nd an ice-bag, which had been kept on night and day, was discontinued. Swelling still present, but about half the size it was originally; no fluctuation, and apparently solid; pad and firm pressure applied. On the 27th the swelling was much less; pressure was still kept up by means of a spica bandage, and a small piece of mercurial ointment was placed on the swelling previous to the bandage. She left the hospital on Dec. 11th, quite cured; no sign of the swelling remained.

Maddox-street, W.

ACUTE PERFORATING ULCER OF THE ASCENDING COLON.

BY JAMES OLIVER, M.B. EDIN., M.R.C.P. LOND.

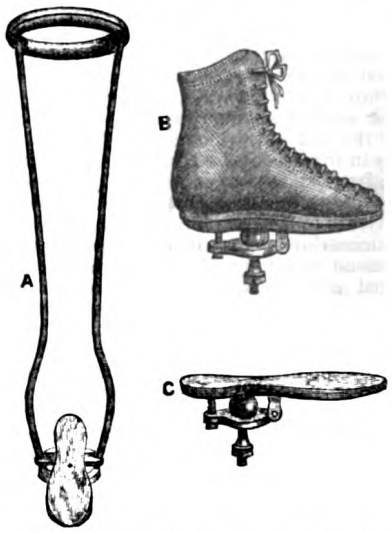
IT has been asserted, and doubtless correctly, that perforating ulcers—leaving out of consideration typhoid, tubercular, and such allies—may, and do, occur throughout the gastro-intestinal canal. The stomach and duodenum are, however, apparently the situations preferred. Few cases are on record where the colon itself has been the seat of perforation. Duodenal ulcer has frequently been noted in connexion with extensive burns of the body; the causation, however, must still remain a mystery. Simple inflammation of the gut rarely gives rise to perforation. Considering how common, comparatively speaking, inflammatory changes in and around the cæcum occur, it is somewhat astonishing that complete ulceration so seldom results. In the case which forms the basis of the few remarks I have to make the ascending colon was the seat of perforation. Two ulcers were discovered side by side longitudinally in the large intestine, two inches and a half above the ileo-cæcal valve. The larger was about half an inch in diameter, whilst the other was only large enough to admit the tip of a goose-quill. The surrounding tissue was apparently healthy, as well as that intervening between the two openings. Both perforations were round in shape, their margins being perfectly regular. The various coats of the bowel had necrosed to an equal extent throughout; the muscular, however, had retracted, and a partial prolapse, so to speak, of the apparently redundant mucous membrane had resulted. The larger opening from the outside gave the appearance of an artificial anus, whilst the smaller was barely to be detected because of the recoil of the elastic tissue of the gut. The position of the ulcers was as nearly as possible the middle of the posterior surface of the ascending colon. Posteriorly this part of the colon, deriving no covering from the peritoneum, is attached by connective tissue to the fascia covering the quadratus lumborum and the front of the right kidney. Gradually by necrosis, the bowel having become tunnelled, fæcal matter escaped into the areolar tissue, separating by degrees the colon and right kidney from the underlying structures. The peritoneum showed but little sign of inflammatory change, the lower margin of the liver alone betraying any sign of fibrinous exudation, and this but limited. The etiology of perforating ulcer is still a debatable question. It is more than likely, however, that thrombosis is a probable cause, the change resulting being comparable with that occurring under similar circumstances in the brain and spinal cord. Complete occlusion of the small blood channels brings about a gradual death of the part by staying effectually its nutrition. It is doubtful whether the gastric or intestinal secretions ever aid in its production.

Montague-street, W.C.

A NEW SPLINT FOR THE TREATMENT OF TALIPES.

BY F. T. PAUL, F.R.C.S.,
SURGEON TO THE ROYAL SOUTHERN HOSPITAL, LIVERPOOL.

IT has always appeared to me, as a general surgeon, that in our ordinary hospital practice cases of confirmed talipes frequently do not obtain the full amount of benefit that is possible—more frequently, I mean, than other varieties of remediable defects. I suppose that this might be explained, if it be really a fact, in different ways by different surgeons. The explanation that has occurred to me is simply that the mechanical treatment following any operative procedure needs to be so prolonged, and so assiduous during the whole time, that the careful patience of either the surgeon or the



patient often breaks down before the cure has been effectually and permanently established. I have been in the habit of using sheet iron side splints with a foot-piece, fixed on by first firmly strapping the foot to the foot-piece while the foot is in its deformed position, and then forcing the side splint to the leg, and so reducing the deformity. This plan answers well enough if the splint be refixed every few days for six or twelve months. In my own practice I observe that I keep up a pretty close supervision of the case for a month or two, then it gradually drops entirely into the hands of my house-surgeon; subsequently it falls to the care of the nurse, and lastly is lost sight of for a time, and when seen again is often as bad as when it first came under treatment. For a long time I have felt that if a surgeon had the time to undertake a complete supervision of his cases of talipes he could usually cure them by simple mechanical means, and it was owing to the unsatisfactory results that I constantly met with in the practice of my colleagues as well as myself that I attempted to devise a splint which would be so easy to manipulate that the surgeon could himself take in hand the treatment of his talipes cases without that loss of time which at present frequently causes us to relegate the duty to someone else. The splint (see figure) consists of the ordinary side rods and padded ring of a Thomas's knee splint (A). Joining the side rods at the bottom is a ring to walk upon and a cross-bar from one to the other. This latter has a slot in the

middle part of it, in which a strong steel ball can be fixed. The ball works in a socket attached to a plain wooden foot-piece (C). The foot-piece is screwed to the socket by three or four ordinary screws, which can at any time be taken out and a boot attached instead when the treatment is sufficiently advanced (B).

The method of applying the splint is as follows:—The foot-piece with the ball-and-socket joint is taken out of the splint, the joint unscrewed, and the ball removed, so that strapping can pass under the foot-piece anywhere. The child's foot is then very carefully strapped to the foot-piece in such a manner that it will not require to be renewed for some time. The ball is then replaced and loosely screwed up, and the foot-piece with the limb fixed to the splint. It is unnecessary as a rule to put on more than a couple of straps round the leg and splint, but when inversion is marked a better fixation of the limb will be required in order to be able to evert the foot. All that is left to be done is to gently force the foot into a somewhat improved position and screw up the ball-and-socket joint. At the next visit this is loosened and refixed in a still better position; and as it is only the work of a minute, it can be undertaken by the surgeon as he makes his daily rounds. Children walk about easily in these splints, and so far I have met with very good success in using them. If only one leg is affected, a high sole should be made to the opposite boot to avoid obliquity of the pelvis.

The drawback for hospital use is the cost. There is a good deal of work in the splint, and it must be well done or the joint will not remain fixed when in active use. Mr. Critchley of Liverpool has taken great pains to carry out my instructions in making the splint, and has succeeded very well. He supplies them to the hospital at a sovereign each.

Liverpool.

A RARE CASE OF SPINA BIFIDA.

By W. T. CREW, F.R.C.S. Eng.

THE following case seems to me worthy of record in the pages of THE LANCET.

A full term, well-nourished infant, a day old, the first child of a mother aged twenty-one, was brought to me early in December of last year. Over the lumbar spine in the middle line was a sessile tumour measuring about one inch and a third longitudinally, and slightly less transversely, and raised five-eighths or three-quarters of an inch above the integumentary surface. Its appearance exactly resembled a blister, with two exceptions—namely, first, that a few minute bloodvessels could be detected on its surface; and, secondly, about its centre, over a circular area, the diameter of which was about half an inch, the spinal cord, or rather the cauda equina, was bare, and presented somewhat the appearance of an ulcer, from which a clear fluid exuded. By transmitted light (daylight was quite sufficient), the cauda equina could be clearly seen leading up to this spot. The tumour appeared to swell out as the child cried. For further examination I oiled my fingers, as I feared the sac would burst by rough manipulation. On slight pressure the edges of the fissure in the spinal canal could be easily defined, small buttresses of bone being distinctly felt all round the base of the sac, which I regarded as the edges of the deficient vertebral laminæ. On examining the head the fontanelles were unusually large, and the sutures between the various bones were excessively wide, and during violent expiratory efforts the meninges became very prominent. At the junction of the frontal and nasal bones was a rounded meningocele, and on the left side, through a large Wormian bone in the parietal region, was another meningocele the size of a large marble or small walnut. Several large Wormian bones were present in the frontal and parietal bones, and one in the occipital. Both thighs were tightly flexed on the abdomen, and both legs flexed on the thighs. The right foot was in a condition of severe talipes calcaneus, the left less so. The toes of the left foot were strongly flexed; the arms and fingers appeared to move naturally; there were no convulsions, and the child, otherwise well, took kindly to the breast. On the second day after birth the cerebro-spinal fluid began to escape through a small aperture which had formed in the sac, and continued to do so. On the fifth day the sac began to feel firmer at its base; the integument appeared to be spreading over the tumour. The clear fluid now became turbid, and on the ninth day the whole sac was much thicker and less translucent, partly owing to the cutaneous overgrowth, and partly to the deposit of inflammatory materials in its interior. Four weeks after birth the tumour was smaller; its surface resembled normal skin, except for bluish, almost nævoid congestion. Pus now came away freely from the aperture. That portion where the spinal nerves had been bare had now become covered over with skin. The meningoceles disappeared; but the protrusions of the cerebral membranes were more distinct between the various sutures, which showed no signs of contracting. The distortions of the lower extremities became more pronounced, and the child wasted. At the end of the fifth week slight convulsive seizures began, and in the sixth week the patient died. On opening the spinal canal after death, there was exposed a fissure in the whole of the lumbar region of the spine an inch and a half long and three-quarters of an inch wide. The bodies of the vertebræ appeared normal. Spinal meningitis was well marked, and the sac was filled with lymph and pus. The head was not interfered with.

Although it was impossible to verify it post mortem, I believe the sac was originally formed of the spinal arachnoid only, the bluish-white appearance said to result when the spinal dura mater is exposed being entirely absent. I may say that the mother, in describing its primary appearance, spoke of it as "like a water-bleb," which I thought very apt. The other point in the case which I thought remarkable was the long period (nearly six weeks) which elapsed before the fatal termination; and it was interesting to note the failure of development of the cranial bones in conjunction with those of the spine.

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas at morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

ST. THOMAS'S HOSPITAL.

THREE CASES OF SARCOMA OF THE TESTIS; CASTRATION; RECOVERY.

(Under the care of Mr. SYDNEY JONES.)

THE importance of diagnosis in cases of enlargement of the testis is very great, for *early* removal of malignant disease is a large factor in the ultimate result aimed at—namely, complete cure. It is, however, difficult in the early stage of enlargement of a testis to give a decided opinion, and in many cases even the best authorities can give no definite diagnosis until various remedies have been tried and the tumour punctured; the latter with a view of examining the fluid withdrawn and any growth brought away in the cannula. Our readers will recollect that the chief difficulty at the commencement is to diagnose the disease from chronic inflammation of the body of the testis, and later from chronic hydrocele and from hæmatocele; and this task is rendered more difficult when the attention of the patient has been first directed to the diseased organ by a blow or other injury, as in two of the cases recorded by Mr. Sydney Jones. A progressive solid enlargement of the body of the testis, without evidence of inflammation, the surface being of unequal consistency, with dilatation of the scrotal veins, should always be looked upon with suspicion, more especially if treatment prove of no avail in arresting the increase of the growth.

CASE 1.—G. S——, aged twenty-one, a potter, was admitted under the care of Mr. Sydney Jones, Jan. 22nd, and left, apparently cured, March 5th, 1884. The family history was good, and the patient had enjoyed excellent health until four months and a half before admission; he had never suffered from any venereal complaint. Eight or nine months before admission he noticed a small hard lump about the size of a pea on the outer and upper side of the right testicle,

which slowly increased in size, but which was at first freely movable. Four months and a half ago he knocked his right testis against a table, and the injury was followed by rapid swelling; so much so that it was the size of the patient's fist on the following morning. It was quite soft and doughy at first, and diminished in size somewhat after the application of ice; but in a few days became quite hard, and had since grown slowly. The pain caused by the injury was not severe, and there had been no pain since. After the accident he could feel the small swelling which had existed previously in the middle of the soft swelling, it being then about the size of a walnut, but when the swelling became quite hard it could no longer be felt. When admitted he was complaining of the swelling of his right testicle, and appeared somewhat anæmic, pale, and was rather thin. On examination, there was an oblong, somewhat pyriform swelling occupying the right half of the scrotum and bulging into the left half. It was hard and elastic, and no decided fluctuation could be felt. It extended into the highest point of the scrotum, and could be traced as high as the external abdominal ring. Underneath the tumour a projection from it, like an enlarged testicle, could be made out, but no pain was felt on pressure, either over this or any other part of the tumour. There was no testicular sensation. There was no impulse on coughing, and the size of the growth did not vary. The superficial veins of the scrotum were enlarged on the right side. The glands in the groins were not enlarged, and no enlargement could be felt in the glands of the abdomen. The patient was otherwise apparently healthy. There was no albuminuria.

Jan. 22nd.—The tumour, which had been punctured in the out-patient department before admission, was again punctured, and, as on the former occasion, only bright blood flowed through the cannula; examined microscopically, this showed no evidence of new growth. From above downwards the growth measured 11¾ in., and the greatest circumference 8¾ in.

30th.—There had been no diminution in size under the application of ice, ordered on the 26th, and Mr. Sydney Jones decided to examine, and, if necessary, remove the tumour. The parts having been shaved and washed with 1 in 40 carbolic solution (the patient being under the influence of ether), a vertical incision was made, about an inch to the right of the raphe, through the scrotal tissues down to the tumour, which was found to be of sarcomatous nature; an elliptical incision was then carried from the external ring to the lowermost portion of the growth and back to the starting-point; the tumour was then rapidly dissected out, the numerous vessels being caught with clamp forceps; the cord was then seized with a stout pair of clamp forceps, the tumour being cut off below. Numerous ligatures were required to arrest the general bleeding, and the cord was ligatured. The edges of the wound were carefully adapted by means of silk and catgut sutures, a drainage-tube was placed from the highest point of the wound, and, after the parts had been thoroughly washed with carbolic solution, the ordinary antiseptic dressing was applied under the spray, which had been employed during the operation. When the growth was incised, the cut surfaces bulged out and presented a gelatinous structure, which appeared to have grown from the upper part of the testis; but this organ could not be distinguished. Microscopically the growth was sarcomatous, and consisted chiefly of small round cells. There was some clear fluid in the tunica vaginalis, into which small bosses of new growth projected. The patient vomited after the administration of the ether. At night the temperature was 98·8°.

31st.—At 2 A.M. the temperature was 100·2°; at midday 101·8°; at 8 P.M. 99·8°. There was no pain, and he had slept well.

Feb. 4th.—Wound dressed. Some purulent discharge from the upper part of the wound on pressure. Wound somewhat offensive in smell. Two stitches removed. The temperature has varied from 99° in the morning to 100·4° in the evening. No pain whatever.

6th.—Wound redressed; a good deal of pus came from the wound, especially from the upper part; edges of wound slightly red and tense. Carbolic dressings discontinued and boracic acid substituted. The temperature has varied from 98·4° to 100·2°. The bowels were freely open after enema on the 5th.

After the 6th the temperature became normal or subnormal, not reaching 100°, excepting during an attack of follicular tonsillitis, which lasted from the 14th to the 17th, when it rose to 102·6°. There was discharge from the wound, chiefly from the situation of the cord, until nearly the end of the month, when the wound had perfectly healed. There was some slight swelling over the canal in the position of the stump of the cord when the patient left.

On leaving the hospital the patient went to a convalescent home, where he remained for three weeks, resuming work as a potter on his return to London. He was readmitted into St. Thomas's on Oct. 7th, under the care of Dr. Ord, and died on Oct. 29th. It appeared that about three months before he had suffered from constipation, and had also had some vomiting; these symptoms passed off for a time, and he does not appear to have paid much attention to them until he found a lump in his abdomen during a more severe attack, three days before admission. When under care the symptoms were constipation, vomiting, distension of the abdomen, and the presence of a large tumour in the right side and in the iliac fossa. He died from exhaustion. There was a small growth in the inguinal canal, measuring about three-quarters of an inch in diameter, a growth as large as an orange over the iliac vessels on the right side, several tumours under the ascending colon on the same side, evidently of glandular origin, and another growth behind the duodenum, adherent to it about four inches from the pyloric end of the stomach; and on examination of the mucous membrane of the duodenum it was found that the growth had produced an ulcer about two inches long. The growths on section closely resembled each other, presenting a gelatinous appearance, some being more vascular than others. These secondary growths much resembled the original one.

CASE 2.—G. G——, aged fifty-one, a sawyer, was admitted into the Albert ward under the care of Mr. Sydney Jones, April 7th, and left cured April 28th, 1884. There was no family history of tumours. The patient, a strong, healthy-looking man, had had no severe illnesses; he had not had syphilis. The patient stated that between five and six years ago he had received a severe blow from a log of wood on his right testicle; this caused considerable pain, but he was able to return to work in about half an hour. The next morning he noticed some swelling on the right side, which became considerable in about three days, and the scrotum very red. He went to Guy's Hospital, where they wished him to remain as an in-patient, but he refused. He was unable to work for about a fortnight, because of severe aching pain in the testicle. The pain then ceased, but the swelling did not diminish, and remained about the same size until a year or eighteen months ago, when it commenced to steadily increase, and that without pain, excepting from its weight, which produced aching in the loins. On examination the scrotum was found to be occupied by a large pyriform tumour, measuring from above downwards ten inches. It occupied the whole of the right side of the scrotum, and the testicle on that side could not be discovered. The left testicle was normal, and could be easily separated. The tumour was very heavy, elastic, almost fluctuating in some parts, in others hard; the swelling was not translucent. It did not involve the cord to any extent, as this could be traced into the upper part of the tumour and presented no evidence of enlargement. The superficial veins of the scrotum were much dilated. No enlargement of glands could be discovered. General health good. Sp. gr. of urine 1010; no albumen.

April 9th.—Ether having been administered, and the parts washed with carbolic solution and shaved, two curved incisions were made from above downwards, including an oval piece of the skin, and meeting at the bottom of the scrotum; the remainder of the scrotum was then dissected off the tumour and the cord freed, clamped, and the tumour removed; the cord was ligatured. The vessels, which had been secured by clamp forceps as they presented themselves in the wound, were ligatured; a drainage-tube was introduced; the edges of the wound brought together with silk and catgut, and antiseptic dressing applied; the spray was used throughout the operation. On section of the tumour the cut surface was undoubtedly of a sarcomatous character; there was some fluid, especially in the tunica vaginalis, where some nodulated growths were found in its wall, projecting from the principal one. Examination of the growth some time later proved it to be sarcomatous, chiefly small round cells. The abdomen was carefully examined whilst the man was under ether, but no enlargement of the lumbar glands could be felt.

10th.—The patient had slept fairly during the night and

was without pain. Pulse 108. The temperature on the evening of the 9th was 98·4°. The wound was redressed antiseptically; there was very little discharge. On the 10th the temperature rose to 100·6° in the morning, and to 100·8° on the 11th, but fell again next day, becoming on the 13th and after the 15th subnormal, continuing so for the remainder of his residence (it had been normal before the operation). On the 16th carbolic oil was used instead of the antiseptic dressing, and warm water dressing was substituted for this on the 18th. The wound was healed when he left the hospital, nineteen days after operation.

CASE 3.—W. W——, aged thirty-six, a labourer, was admitted, under the care of Mr. Sydney Jones, on Sept. 22nd, and left, cured, on Oct. 8th, 1884. The family history was good; there was no history of any tumour. He had had no serious illness, and had never suffered from syphilis. He first noticed that the left testicle was enlarged a short time before Christmas, 1883; the swelling began at the lower part of the testicle, and had gradually increased in size. The growth had been unattended by pain, and had only caused inconvenience from its size. There was no history of injury. When admitted the patient was a strong, healthy-looking man, complaining only of enlargement of his left testicle; this enlargement was considerable, the swelling being very hard and lobulated at its posterior part and irregular on the surface. The hardness was almost cartilaginous in character, there was no testicular sensation, and the outline of the testicle was lost. The cord on the left side appeared larger than that on the right; the superficial veins were enlarged on the left side of the scrotum. No enlargement of the glands could be detected in the abdomen. The internal organs appeared healthy. Urine normal; sp. gr. 1015.

Sept. 23rd.—The tumour was tapped, but nothing flowed through the cannula; a little clot which remained in the end, on withdrawal, when examined microscopically, showed only red and white blood-corpuscles.

24th.—Ether having been administered, Mr. Sydney Jones removed the testicle, antiseptic precautions being adopted throughout the operation, as in the other cases. Two curved incisions were made, including an oval piece of skin, the tumour dissected out from the scrotum, the cord cleared and clamped, and the growth removed below. After this the vessels, which had been secured by clamp forceps during the progress of the operation, were ligatured, and then the vessels of the cord itself were separately ligatured. The edges of the wound were brought together by alternate silk and catgut sutures after the insertion of a drainage-tube, and the wound dressed antiseptically. Examination of the tumour showed a nodulated mass with the naked-eye characters of a sarcoma. On section there were several small cysts; the growth appeared of more recent origin in parts, and in one part it appeared as if there was some remnant of the testicle. No record of the microscopical examination was kept.

24th.—Slept after an injection of morphia, and was in no pain. Pulse 96.

25th.—Wound redressed under the spray; looked healthy.

27th.—Wound redressed; a few stitches removed. The patient complained of headache, but was otherwise well.

30th.—The wound was redressed, and all the remaining stitches and the drainage-tube removed.

After the operation, the temperature in the evening rose to 100·8°, to 100° on the following day, and to 100·6° on the day after. It did not again exceed 99·6°, becoming and continuing normal until his discharge, thirteen days after operation.

STATION HOSPITAL, HULME.

ENLARGEMENT OF THE BURSA BENEATH THE SEMI-MEMBRANOSUS AFTER INJURY; SUPPURATION EXTENDING TO THE KNEE-JOINT; ASPIRATION; AMPUTATION; RECOVERY; REMARKS.

(Under the care of Surgeon-Major G. C. GRIBBON, M.B.)

CORPORAL C——, 3rd Dragoon Guards, aged twenty-seven years, was admitted on Jan. 21st, 1884, with an obscurely fluctuating swelling on the inner and upper part of the left calf about three inches below the joint. He was employed in the saddlery workshop. Six months prior to coming under treatment his horse fell with him, and rolled over on his left leg, giving rise to considerable bruising. This passed away without any apparent ill effects, and he was able to resume his usual occupation as a saddler. Latterly, however, he had felt the left knee stiff, especially after sitting any length of time at his work, and he had got an uneasy feeling in the calf. The patient was a delicate-looking man of very strumous appearance. The left popliteal space appeared somewhat full.

Five days after admission the swelling had become more prominent and fluctuation distinct. It was rather tender, and occasional shooting pains were felt down the leg. Exploration with a fine needle showed the contents to consist of oily matter, with a few opaque streaks. Under antiseptic precautions about an ounce of fluid was evacuated through a small incision, and after a few days, during which there was a little thin oily discharge, the opening closed up. He was able to resume work on Feb. 4th. On the 17th, however, the man returned to hospital with a feeling of tightness and stiffness at the back of the knee, and some pain down the leg. There was no swelling in the calf this time, but the lower part of the popliteal space appeared fuller than normal. His general health was not good.

During the following two days the swelling increased rapidly, and as it was tense, it was again emptied, and rest and pressure employed, but without effect, for reaccumulation occurred; it was therefore determined to make a free opening and use continued drainage. This was done on March 23rd. Antiseptic precautions were used throughout.

The patient progressed satisfactorily enough for the following four days. All his discomfort was relieved, and he felt so well that, disregarding instructions to remain in bed and at rest, he got up and walked about in the hospital yard. The day was cold and damp, and on returning to his ward he felt his knee very cold and numb, and soon afterwards pain set in. Acute synovitis of the knee supervened, the temperature ran up to 103°, the febrile symptoms were marked, and the discharge from the wound became more puriform. On the supervention of inflammatory symptoms immobility was secured placing the limb in a long back splint with heel-piece. Cold, leeches, &c., were used, but to no avail. The synovitis became evidently suppurative.

On April 18th the joint was aspirated, and 4 oz. of healthy pus removed. This procedure, it was intended, should be merely preliminary to freely opening the joint and securing free drainage; but the relief given was so great that the latter operation was postponed, in the hope that repeated aspiration might prove effectual. Mr. Heath, Senior Surgeon to the Royal Infirmary, Manchester, thought similarly. He informed Surgeon-Major G. C. Gribbon that in a case under his care of acute suppuration of the joint aspiration had resulted in complete recovery (THE LANCET, Sept. 4th, 1880, p. 379). After each aspiration relief was experienced, and the febrile symptoms were temporarily allayed. The joint looked a little puffy, but there was no pain, and but little tenderness present. After ten days, however, the symptoms, indicative of progressive inflammatory mischief, recurred with severity. Hectic became marked, and the patient was much reduced and exhausted. The joint became more painful, with startings on the slightest movement, and slight œdema of the thigh appeared. As suppuration was undoubtedly extending along it, amputation of the thigh was decided on, and performed on May 9th. The patient made an excellent recovery. Examination of the joint presented the usual features of a destructive inflammatory process. The synovial membrane was thickened and softened, and the articular surfaces were eroded circumferentially. Subchondral caries allowed of easy removal of what remained, which was soft and discoloured. The periarticular tissues were swollen and infiltrated, and collections of pus were found extending along the muscles of the thigh. The opening made early in the case behind the joint could only be traced for an inch inwards. No communication through it with the joint could be made out.

Remarks by Surgeon-Major GRIBBON.—Cases of enlargement of the bursa under the semi-membranosus are not uncommon, but one of so active a kind as in the present case is, I think, exceptional. That the swelling first observed on the calf and afterwards in the lower part of the popliteal space was from inflammation of this bursa is hardly doubtful. In the place where it first showed itself—i.e., the calf—the case resembles some of those published by Mr. Morrant Baker in the thirteenth volume of St. Bartholomew's Hospital Reports under the title of "Synovial Cysts

of the Leg in connexion with Disease of the Knee-joint," but his are all connected with chronic disease and a result of it, whereas in this the swelling preceded the joint affection and became the predisposing cause. Perhaps the most interesting point in the case is whether there was any communication between the bursal swelling and the joint. Such a communication is said to exist in one out of every five cases. Here it was impossible to say, for though none could be detected on examination of the limb after amputation, it is far from improbable that it might have existed, but got blocked by the inflammatory processes going on near it. It is clearly important that this communication should be borne in mind in the treatment of enlargements of bursæ in close relation to joints. The treatment by incisions, after the valvular method of Abernethy and with antiseptic precautions, proved safe but inadequate. The free opening of the sac promised well until the patient's indiscretion subjected him to the acute inflammatory attack which ultimately destroyed the entire joint.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Annual General Meeting.—President's Address.

THE annual general meeting of this Society, for the election of officers and other members of the Council for the ensuing year, was held on Monday last, Dr. George Johnson, F.R.S., President, in the chair. The list of officers for the ensuing year was given in our issue last week.

Dr. DOUGLAS POWELL read the report of the President and Council, which showed that fourteen Fellows had died during the past year, including Dr. Allen Thomson, an honorary Fellow, and Dr. Samuel Gross, a foreign honorary Fellow. During the past year thirty-one Fellows had been elected. The total number of Fellows at the present time was 731. The report showed further that the average attendances at the meetings of the Society compared very favourably with those of the past years. The number of works in the possession of the Society was 29,222. An endeavour had been made to increase the number of engravings in the possession of the Society. Dr. Blandford had kindly undertaken to edit a catalogue of the Society's large collection of engraved portraits of members of the medical profession.

Dr. ALTHAUS moved that the report of the President and Council, together with the balance-sheet of the treasurer, be received, printed, and adopted.

Dr. BERNARD O'CONNOR seconded the motion.

Mr. COOPER FORSTER, as treasurer, made a few explanations connected with the balance-sheet.

The PRESIDENT then read the annual address, which was chiefly composed of obituary notices of deceased Fellows—viz., six resident Fellows—Dr. Barclay, Mr. Fairlie Clark, Dr. B. Baxter, Dr. A. King, Sir Erasmus Wilson, and Mr. Cæsar Hawkins; and six non-resident Fellows—Dr. S. Denton, Mr. Arnold, Mr. J. S. Daniell, Dr. W. Corley, Dr. Lashmere, and Dr. Worthington, and two honorary Members, Dr. Allen Thomson and Dr. S. Gross, had been erased from the muster-roll of the Society by the hand of death. After giving very full accounts of the more eminent of the deceased Fellows, the President made a few retrospective and prospective remarks on the work of the Society, which showed clearly that the papers, and discourses thereon, were in no danger of falling off. Allusion was made to the improved state of the drainage of the Society's premises, and the President suggested that a more efficient method of ventilation might be adopted for the room in which the meetings were held.

Dr. WILSON FOX proposed and Dr. BUZZARD seconded a vote of thanks to the President for his address.

The vote of thanks to the retiring members of the Council was proposed by Dr. CHOLMELEY and seconded by Mr. VICTOR HORSLEY.

Dr. GERVIS and Dr. LEGG officiated in the vote of thanks to the retiring treasurer, Mr. COOPER FORSTER.

The vote of thanks to Mr. Berkeley Hill, the retiring secretary, was proposed by Dr. DYCE DUCKWORTH, seconded by Mr. R. W. PARKER, and carried with acclamation.

PATHOLOGICAL SOCIETY OF LONDON.

Rhino-scleroma.—Sarcomata of Bladder.—Congenital Obstruction of Intestine.—Adeno-sarcoma of Pineal Body.—Fractures of Hyoid Bone and Larynx.—Tubercular Pyo-Salpinx.—Peculiar form of Nephritis.

AN ordinary meeting of this Society was held on Tuesday last, Dr. J. S. Bristowe, F.R.S., President, in the chair.

Dr. PAYNE and Dr. SEMON read a conjoint paper on a case of Rhino-scleroma which they had shown to the Society on Oct. 21st. 1884. Drawings and microscopical specimens were also shown. The patient was a Guatemalan, aged eighteen, who had suffered for four years. The disease began insidiously. Two rounded, reddish, firm swellings, each about the size of half a hazel nut, ulcerated on the surface, were situate below the nostrils; both nostrils were filled with similar masses. The bridge of the nose was considerably broadened, and on pressing it below the bones gave a sensation of stony hardness. Galvano-cauterisation was said to have caused the ulceration. The uvula had entirely disappeared. Upon the soft palate an irregular, raised, whitish, slightly ulcerated patch was seen. The palate had undergone considerable cicatricial contraction, fibrous bands running from the ulcerated patch in all directions, and greatly distorting the parts. Similar morbid changes were visible on the left tonsil and left lateral wall of the pharynx. The larynx and naso-pharyngeal cavity were unaffected. The patient was extremely anxious to have some operation performed, which should remove the external disfigurement and the impediment to breathing through the nostrils, although the impossibility of a radical cure, and the improbability of a lasting improvement, were strongly represented to him. Before proceeding to operative measures, energetic anti-syphilitic treatment was had recourse to, and continued for some months, but without any result. The day after he had been shown to the Society he was put under chloroform, the external tumours and the masses blocking the nostrils were radically scooped out with the sharp spoon, and the exposed surfaces on this and the following days freely cauterised with lunar caustic. In spite of these precautions, two months after the operation unmistakable signs of recurrence made their appearance. Further operative interference was declined, as apparently useless, and the patient was lost sight of. It was found that the greater part of the septum nasi had entirely disappeared. As no trace of bone was detected in any of the numerous sections which were made, it could only be assumed that the partition had been destroyed by the progress of the growth. The histological examination showed the skin and, in the upper parts, the mucous membrane to be invaded by a small-celled growth, resembling granulation tissue, with an admixture of some larger cells of a different form. The epidermis was also altered in a peculiar manner, producing concentric masses, with some resemblance to the "nests" of epithelioma. There were also firm masses of fibrous tissue. The whole structure was entirely different from epithelioma or sarcoma, or any other definite tumour formation, but formed a growth more resembling the granulation tumour, such as lupus, syphilis, tubercle, than anything else, though quite distinct from any of these. It was remarkable for the absence of any evidence of atrophy or degeneration. The histological appearances were, in the main, the same as have been observed in all cases of rhino-scleroma, though these appearances have been differently interpreted by different observers. This is believed to be the first case of this rare disease ever described in this country; and no other case but this has been described in France. In Germany (out of Austria) the disease is equally unknown, most of the reported cases having come from Vienna; a few had been seen in Italy.—Mr. BUTLIN asked whether any parasite had been found.—Dr. PAYNE replied that micro-parasites had been found, but not in the present case.

Mr. EVE showed two specimens of Sarcoma of the Bladder. The first specimen was a firm pale lympho-sarcoma, which occupied the anterior and upper walls of the bladder, which it fixed, except an elongated space, one inch in width, at its lower and posterior part. The greatest thickness of the tumour was three inches and a half; its free surface was not papillary. Microscopically, the tumour was composed of lymphoid-like round cells, forming ill-defined masses and groups in a scanty fibrous stroma, and

lying in the meshes of a reticulum of hyaline fibrils. The specimen was taken from a man aged sixty-eight, who suffered for two years from pain in the loins and slight hæmaturia. This bladder was several times sounded for stone. The second specimen was a mixed and probably myo-sarcoma of the bladder, forming a firm fibrous tumour, about an inch and a half in length, and situated within the left wall of the organ just above the ureter. It projected externally from the bladder wall, but the corresponding under-surface was unaltered, with the exception of a slight superficial erosion. Under the microscope, sections showed bundles of unstriped muscle fibre separated by tracts of connective tissue; the bundles were infiltrated with round and elongated nuclei, and with large spheroidal cells possessing a large nucleus, surrounded by a rim of clear protoplasm; the latter formed in parts small ill-defined groups in the muscular bundles, and in the connective-tissue, or were diffusely scattered. Indications of a new formation of unstriped muscle fibre from elongated nuclei were observed in many places. The bladder was taken from an elderly lady, but no clinical details of the case had been obtained.—Mr. H. T. BUTLIN agreed that the first specimen was one of lympho-sarcoma. With regard to the second specimen, he suggested that it might have originated from the prostate gland. He referred to a contribution by Dr. Coupland, which showed that true sarcoma of the bladder had been observed. He said that Mr. R. Williams had thought that sarcoma of the bladder was not so very uncommon, but that out of all the cases of vesical tumour recorded by Sir H. Thompson every tumour was found to be epithelioma or papillary tumour by Dr. Gibbes, and not one sarcoma.—Mr. BOWLBY said that he had seen at St. Bartholomew's Hospital recently two cases of sarcoma of the bladder, both of which had been under the care of Mr. Morrant Baker. Both occurred at about the age of forty. One case was that of a woman. The tumour was a mixed-celled sarcoma. The case of the man was first seen for dysuria. Though an operation was performed, yet extension of the growth and exhaustion led to death. The autopsy revealed the tumour in the bladder, which was of the mixed-celled variety. The growth did not affect the glands in either case, and he asked whether these structures were involved in Mr. Eve's cases.—Mr. EVE, in reply, said that he considered the second tumour could not have originated in the prostate. He had not made the autopsy and could not therefore answer Mr. Bowlby's question.

Dr. HOBSON showed a specimen of Congenital Obstruction of Intestine taken from a male infant less than three days old. The child was a seven months' one, and during life had vomited greenish coloured fluid. The rectum was imperforate. There was no evidence of recent peritonitis at the autopsy, but there were numerous delicate bands. The whole large intestine and lower sixteen inches of the small intestine resembled a solid tube a quarter of an inch in diameter, filled with semi-solid mucous matter; above this the bowel was dilated. A break in the continuity of the intestine occurred at a point just opposite to the occlusion, the mesentery being complete. The peritoneum, especially near the gap, was much pigmented. The mother stated that when five months pregnant she had had a violent fit of coughing which caused her great pain in the abdomen, and he thought that at this moment, either by the forcible bending of the fœtus itself or from some other cause, a rupture of the bowel had taken place, and that consequent inflammatory action had obliterated the gut at the opposite end of the loop.

Dr. CHARLEWOOD TURNER read a paper on a specimen of Adeno-sarcoma of Pineal Gland. The tumour had a nodulated and rounded flattened oval outline, and was about the size of a kidney. It filled and distended the left lateral ventricle, and the third ventricle, and had destroyed the corpus callosum. The tumour was found to have flattened the left optic thalamus, and to have pressed upon the corpora quadrigemina. A careful examination proved that the tumour had originated in the pineal body. The growth had extended forwards in the direction of least resistance into the third and lateral ventricles. The microscopical sections showed a lobulated structure separated by bands of fibrous tissue of loose structure, which contained elongated and angular cells, which stained with carmine. The lobulated portion showed a reticulum of spindle-celled sarcomatous structure, which was traversed by tracts of adenomatous growth. Cells having the character and arrangements of sarcoma and carcinoma were found distributed through the growth. Virchow had described hyperplasia of the pineal gland. Wilks and Moxon had described cystic tumours of this body. Dr. Turner dwelt at considerable length on the pathology of morbid growths. Dr. Hale White said that tumours of the pineal gland though rare had yet been found in every variety. A writer in Virchow's *Archiv.* had described cartilaginous and other kinds of tumours.

Mr. ARBUTHNOT LANE read a paper on Fracture of the Hyoid Bone and Larynx. He had seen nine instances out of 100 bodies examined in the dissecting-room. He said that Mr. Durham had collected seventy-five recorded cases of fractures of the larynx and hyoid bone, of which fifty-nine proved fatal. Fischer's statistics of fractures of the hyoid bone alone showed twelve deaths in twenty-three cases; so that out of a total of eighty-two cases of fracture of the larynx and of the hyoid bone, twenty-eight only recovered, or one-third of the total number. If the statistics given be correct, there must necessarily occur among every 100 people of the pauper class at least twenty-seven fatal cases, which proportion is absurd. Mr. Lane described (1) ununited fracture of the right great cornu of the hyoid bone (Pathological Society's Transactions, 1884); (2) fracture of the right great cornu, with ununited fracture of both superior cornua of the thyroid cartilage, with much separation of the fragments; partial dislocation of the lower cornu, deformity of cricoid cartilage, probably the result of fissuring (Pathological Society's Transactions, 1884); (3) fracture of the right upper cornu of the thyroid cartilage with bony union, and ununited fracture of the left upper cornu with much separation of the fragments; (4) fracture of the right upper cornu of the thyroid cartilage, no separation of fragments, fibrous union and probable fracture of the left upper cornu with bony union; (5) fracture of the right upper cornu of the thyroid cartilage with bony union; (6) fracture of the right cornu of the hyoid bone, chondritis of the thyroid cartilage, probably primary suppuration of both laryngeal glands; (7) fracture of the right upper cornu of the thyroid cartilage with much separation of fragments, fracture of the left upper cornu with fibrous union, no separation of fragments, cricord cartilage fractured in front to the right, considerable displacement of fragments with bony union, and fissure in front and to the left; (8) fracture of the left upper cornu of the thyroid cartilage with fibrous capsule; (9) fracture of the left upper cornu of the thyroid cartilage with fibrous union, no separation of fragments, and probable fracture of the left great cornu of the hyoid bone. Cricoid fractures are, as a rule, fatal. Gurlt found no difficulty in fracturing the thyroid cartilage in elderly subjects by backward pressure with both thumbs. Keiller, Cabasse, and Helwig had experimented on the subject with varying success in producing fracture; the age of the cartilage had something to do with the result. Mr. Lane found that fracture of the upper cornua of the thyroid can be produced with comparative ease by compressing the larynx by the hand and then exerting force backwards. If the perichondrium were torn, there was considerable separation of the fragments. He found that the cartilage of later adult life yielded more readily than that which had undergone ossific change.—Mr. BLACK asked whether there was any possibility of the fracture of the cornu of the thyroid cartilage being confounded with normal appearances, for there was normally a detached portion of cartilage in the thyro-hyoid ligament.—Dr. SEMON said that fractures of the larynx were supposed to be amongst the rarest affections of the larynx. If Mr. Lane's propositions were true, then we must alter our opinions of the fatality of fractures of the larynx. He (Dr. Semon) had recently collected cases of fracture of the larynx, and found that three-quarters of them were fatal.—Mr. LANE, in reply, said that most of the fractures occurred near the base of the thyroid cartilage, and he was well acquainted with the normal structures.—Mr. SHATTOCK said that not uncommonly the body of the hyoid bone articulated with the cornu by a false joint; in his opinion one of Mr. Lane's specimens of fracture was of this nature. The acromion articulated with the spine of the scapula by a kind of false joint at times, and this was a fact analogous to what was seen in the hyoid and its cornu.—A committee of Mr. Lane, Dr. Semon, Mr. Shattock, and Mr. Butlin was appointed, at the suggestion of the President, to inquire into the true nature of Mr. Lane's specimens.

Dr. QUARRY SILCOCK showed a specimen of Tubercular Pyo-salpinx taken from a female child aged five years, who was admitted into St. Mary's Hospital for tubercular

meningitis. At the autopsy the signs of a general tuberculosis were present which involved the cord and brain. The great omentum was adherent to the abdominal wall. There were signs of subsided peritonitis. Miliary bodies were scattered over the walls of the intestines. The Fallopian tubes and body of the uterus were distended with caseous matter; the distension was greatest near the fimbriated portion of the tubes, and was especially so on the right side. The uterus was adherent to the posterior wall of the bladder, and a condition of acute anteflexion seemed to be set up thereby. The cervix was healthy. The body of the uterus was largely distended with caseous matter. He showed the specimen as one of rarity in a child, though such cases were not uncommon in the adult. The uterine walls were hypertrophied, and this was possibly due to the efforts made to empty the cavity of its contents. There were no signs of vulvitis, and there was no history of such an affection.—Dr. GRAILY HEWITT concurred in the view Dr. Silcock had taken. The strong fibrous adhesions, no doubt, caused acute anteflexion, which had been of some standing. Had the patient lived this condition of anteflexion would have continued throughout life. With regard to the presence of distension of the body of the uterus, he thought such a condition might lead to distension of the Fallopian tubes, which was a subject that had received comparatively little attention. The state of the uterus might have been brought about by the obstruction to the outflow of the material owing to the strongly anteflexed condition of the organ.—Dr. A. MONEY had met with two specimens of caseous disease of the body of the uterus and Fallopian tubes in children aged about five years. These cases are recorded in the post-mortem records of the Hospital for Sick Children.—Dr. SEYMOUR SHARKEY questioned whether this condition was a rare one. He had seen several specimens in the adult. In a case of stricture of the intestines which he had shown to the Society there was caseous disease of one of the Fallopian tubes. Mr. EVE also said that he had recently seen two cases of this affection within a short space of time.—Dr. CARRINGTON said that the disease was not uncommon in the adult, though it might be rare in children.—Dr. HADDEN said that various degrees of the disease were to be met with in the adult, and Dr. K. Fowler had shown that the affection was by no means rare.—Mr. SHEILD said that some cases were not of a true tubercular nature, but were the result of disintegration of the caseous products of suppurative inflammation.—Dr. PERCY KIDD had seen only two cases of tubercular disease of the body of the uterus out of 200 autopsies on cases of phthisis in the adult. Disease of the Fallopian tubes was much more common.—Dr. GOODHART said that he had tabulated the results of an experience of ten years, and found that he had seen seven cases of tubercle of the Fallopian tubes; twelve cases of suppuration of these parts; eight of cystic disease, and seven of adhesions. The body of the uterus was but seldom affected by tubercular disease, and he had seen only two or three such cases. In his opinion suppurating cases had been mixed up with tubercular ones.—Dr. BRISTOWE said it was plain that the disease was relatively common, and he had recorded a few instances in the earlier volumes of the Transactions of the Society. He was perfectly certain that the disease might exist without giving rise to symptoms during life. Probably the organs were affected as a part of the general disease.—Dr. SILCOCK, in reply, said that he merely contended for the rarity of the disease in children. He had not been able to find the bacilli in the caseous matter of the organs affected, and Mr. Watson Cheyne had informed him that degeneration of the products might explain this want of success. Distension of the body of the uterus was not necessary to the production of a similar condition of the Fallopian tubes. In a post-morten examination of a case of abortion he had found pyo-salpinx without disease of the fundus of the uterus, so that the distension of the fundus was not necessary to the production of pyo-salpinx.

Dr. HALE WHITE showed specimens of a peculiar form of Acute Nephritis. The kidneys were taken from a man who was brought into Guy's Hospital in an unconscious condition. Twelve days before admission he had been knocked down by a cart, since then he had been ill; he was found in an unconscious state in the streets. On admission he was comatose, with stertorous breathing. There was no paralysis and no cardiac murmur. The urine was bloody. He soon died in the comatose state, during which an occasional convulsion was noticed. Croton oil and pilocarpin had no effect. At the autopsy there was no dropsy, sores, scars, or signs of injury, and no evidence of pyæmia. The bladder and urethra were healthy. The only abnormality of any importance was the condition of the kidney. The two were exactly alike, very bulky, firm, and weighed nineteen ounces together. The pyramids were very dark; there was no evidence of chronic Bright's disease. Projecting here and there on the surface were whitish patches, a little raised about the size of a split pea, and looking something like abscesses. Section of the kidney showed these patches to be most numerous in the medullary part. The largest was half an inch in diameter. Each had two zones, an outer crenated one of a pale yellowish-white colour with a greyish tint at its exterior, and an inner dark-brown zone, sometimes breaking down to pus. The kidney structure around each patch was red and inflamed; this inflamed part was sharply marked off from the healthy kidney substance. Those patches in the medulla were triangular with the apex towards the pyramid, and radiately striated in appearance. The diseased spots in the cortex were circular. The pelvis of kidney was normal. Microscopic examination showed that there was slight epithelial and interstitial nephritis. The part which to the naked eye was abnormal showed a large number of pus cells between and in the tubes; the whole had a broken-up appearance, bits of tubes being here and there visible among the pus cells; sometimes this process had extended far enough to form a definite abscess. The great rarity of this condition was pointed out. It was not scarlatinal, nor was there any history of scarlet fever; it could hardly be due to the injury; there was no evidence of pyæmia anywhere in the body, nor was there anything to suggest "surgical" kidney.

The following card specimens were shown:—Mr. Eve: Enchrondroma of Pelvis, and a recent specimen of Colloid Disease of Omentum. Dr. C. Turner: Necrosis of Renal Pelvis. Dr. Silcock: Croupous Enteritis of Ileum. Mr. John Poland: Ununited Fracture of Internal Condyle of Humerus. Mr. Jonathan Hutchinson, jun.: Lupus Lymphaticus. Dr. Beevor: Nerve Tissues stained by Weigert's new Method. Mr. Marmaduke Sheild: Tumour of Humerus. Mr. Gross: Œsophagus and Parts from a fatal case of Sword-swallowing. Dr. Hale White: A living specimen of a Cryptorchid.

CLINICAL SOCIETY OF LONDON.

Locomotor Ataxy without Disease of the Posterior Columns of the Spinal Cord.—Arrested Rickets.—Nephrolithotomy.

AN ordinary meeting of this Society was held on Feb. 27th, Mr. Thomas Bryant, F.R.C.S., President, in the chair. The first paper elicited considerable discussion, in which Dr. Wilks and Dr. Bristowe joined.

Dr. A. HUGHES BENNETT read notes of a case of Locomotor Ataxy, without Disease of the Posterior Columns of the Spinal Cord. The patient, a man aged forty-eight, suffered from all the usual symptoms of locomotor ataxy, including incoördination of movement, without loss of muscular power, a typical ataxic gait, Romberg's symptom, impaired and retarded sensibility of the lower extremities, lancinating pains, and loss of the knee-jerk phenomena. After death evidences of general acute cerebritis were found with patches of recent softening. In the medulla oblongata there was a mass of sarcomatous infiltration occupying its posterior and central aspects; with the exception of one anterior cornu in a limited portion of the lumbar region, the cord was perfectly normal throughout, as were also the posterior cornua and roots within the circle of the spinal membranes. Outside these the posterior roots in the dorsal and lumbar regions were found involved in a mass of sarcoma, which extended as far upwards as the cervical portion of the cord. In the lumbar region the anterior roots were implicated, but only to a very limited degree. Microscopical preparations and drawings illustrating these facts were shown at the meeting. In commenting on this fact special attention was directed to the pathological and clinical phenomena. It was pointed out that the patches of central softening were probably quite recent, and due to the acute cerebritis which supervened shortly before death. The sarcomatous growth in the medulla was stated to be a rare pathological condition; and the absence of pronounced bulbar symptoms was explained by the supposition that the morbid material had infiltrated the normal structure without

causing serious degeneration. Although one anterior horn was implicated, and some of the anterior roots slightly involved in the disease, it was evident that this had caused few symptoms during life, as the motor power was unimpared, there was no muscular wasting, and the reflex reactions were normal. The clinical point illustrated by this case, to which it was the object of the paper especially to direct attention, was the relation which existed between the spinal symptoms and the lesions in the posterior roots of the cord. It was pointed out that the patient during life suffered from all the prominent symptoms of tabes dorsalis, and presented a fairly typical clinical picture of what we understand of that disease. It was then stated that the universal belief is that the essential lesion of locomotor ataxy is sclerosis of the posterior root-zones of the cord. In the case under consideration there was no trace of disease of any portion of the posterior columns, proving that for the production of ataxy degeneration of the cord is not an essential factor. Reference was made to the cases published by M. Déjerine, in which there were all the symptoms of tabes, and after death only parenchymatous neuritis of the peripheral nerve-endings was found, the cord, roots, and nerves being intact. From this it was maintained that interruption of the different paths at the periphery was capable of causing ataxy in as characteristic a manner as when these tracts were diseased in the cord. The case under notice shows that lesion of a third locality may produce the same effects- namely, at the posterior spinal roots. It was asserted that this was a pathological confirmation of the experimental researches of Van Deen and Claude Bernard, who by dividing the posterior roots induced incoördination of movement without motor paralysis. It supported the view that those elements which convey the impulses regulating coördination are situated in the afferent paths of the nervous system. Whatever theory be advanced to explain the physiology of locomotor ataxy, this serves to show that the point at which, in the causation of the phenomena, the nervous path is interrupted, need not of necessity, as is generally asserted, be primarily situated in the posterior root zones of the spinal cord. Reflection on this fact suggests that we have not yet fathomed the anatomical substratum of that protean disorder which we at present recognise under the term "tabes dorsalis." This assemblage of symptoms probably consists of a combination of different pathological conditions, many of which are represented by phenomena common to all, and each of which may in time be differentiated. It is possible that a case such as the present may prove a link in the chain of discovery.—Dr. SAMUEL WILKS said that the case afforded another proof of the proposition that the pathology of the disease was still unknown. He had seen cases having many of the symptoms of locomotor ataxy end in recovery. With respect to the "classic lesion" of tabes dorsalis, he thought there had been but few cases brought forward corroborative of the dictum of Pierret, that the disease was limited to the posterior root columns of the cord. Cases of sclerosis of the whole of the posterior columns had been recorded in this and other countries. He thought that cases of tabes dorsalis were discussed too much from a physiological rather than clinical or pachological point of view, and he ventured to assert that we were not in a position to discuss the subject from this point of view. Many views had been held of the pathology of tabes dorsalis; cutaneous anæsthesia, loss of muscular sense, and other physiological disturbances had been put forward as the cause of locomotor ataxy. He considered that we had not yet got to the real source of the pathology of locomotor ataxy. He ventured to say that we were too apt to follow the French, and to accept their teachings without sufficient examination. He could not think that the pathological condition of sclerosis of the posterior root zones was sufficient to give rise to every possible symptom of nervous disease. There was not an organ in the body which could not be diseased in tabes dorsalis, and he did not think that such a protean affection could be due to disease of the posterior root columns.—Dr. ALTHAUS said that in general paralysis of the insane the pupils were unequal, whilst in locomotor ataxy the pupils are equal, with a very few exceptions. He considered that Dr. Bennett's case was one of an exceedingly rare condition, for sarcoma was said by Virchow to be of great rarity in the spinal cord. Much speculation had been made concerning the symptoms to be attributed to disease of the posterior roots, and he agreed with Dr. Wilks that we had still much to learn. The duration of Dr. Bennett's case was very brief; locomotor ataxy lasted even as long as twenty-five years, and then the patient died of a complication rather than of the disease itself. He could not follow Dr. Wilks in regard to the belief that cases of recovery from locomotor ataxy could not be due to sclerosis of the posterior columns. Such cases may recover from the clinical symptoms, whilst they continue to have the disease of the posterior columns. He referred to cases which had been recorded in which sclerosis of the entire extent of the posterior columns was found, the patient having died of another disease. He considered that a vicarious action of other parts of the spinal cord could supply the lost functions.—Dr. C. TURNER had made an autopsy and microscopical examination of a case which died at an early stage, which was probably one of commencing sclerosis. There was exudation in the central parts of the posterior columns between the columns of Goll and the root-zone. The serous or albuminous exudation was very extensive. The patient had had some symptoms of tabes dorsalis, such as ataxic phenomena and ocular symptoms. Death followed tracheotomy, which was performed for some laryngeal trouble. He had also seen a case somewhat similar to that of Dr. Bennett's. There was a growth in the fourth ventricle which encroached on the cerebellum; many tumours were disseminated down the spinal cord; in parts the new growths had invaded the posterior columns of the cord. There was loss of reflex action in this case, which occurred in a child. He thought that the occurrence of these exceptional cases did not throw any doubt on the ordinarily accepted views of the pathology of tabes dorsalis. Disease at any part of the course of the circle might give rise to similar groups of symptoms, so that there was nothing strange in the occurrence of the phenomena when the peripheral nerves were alone affected.—Dr. BEEVOR said that Dr. Bennett's case bore on the question whether the disease begins primarily in the nerve tubules or whether it begins in the neuroglia. The growth evidently began outside the nerve tubules, and these were secondarily damaged. In a specimen which he had examined the nerve tubules were seen to be surrounded by a very thick band of fibrous tissue. The pains were probably due to the nerve tubules being compressed by the sclerotic tissue. Cases had been recorded by Buzzard and Adamkiewicz in which the bloodvessels were the primary seats of disease.—Dr. HADDEN said that in cases of alcoholic paralysis symptoms of tabes dorsalis may be present. Dr. Wilks had described cases of alcoholic disease which were very like those of ataxy. He (Dr. Hadden) had reported two cases of alcoholic paraplegia in which there were very marked changes in the peripheral nerves, but none in the spinal cord. The paralysis of the third or sixth nerve could hardly be due to disease of the posterior root zones. He mentioned a case which he had lately seen in which locomotor ataxy was diagnosed by many physicians. At the autopsy sclerosis of the columns of Goll, and symmetrical sclerosis of the lateral columns, were the lesions found. Optic nerve atrophy was also present.—Dr. BRISTOWE thought that Dr. Bennett's case helped to throw a good deal of light on the pathology of tabes dorsalis, for it seemed to show that in the posterior roots there must be all those elements which entered into the formation of the postero-external columns of the cord. The pupils were unequal perhaps in the majority of cases of locomotor ataxy which he had observed. He had never seen recovery of a case of undoubted locomotor ataxy, though he had seen cases in which symptoms which might be mistaken for those of tabes dorsalis have disappeared. He narrated the case of a middle-aged woman who suffered from severe headache, giddiness, and double vision, with staggering gait; there were attacks of profound nausea without vomiting; paralysis of both external recti, of the right internal rectus, and of the portio dura was present. There was also paralysis and tingling of the right arm, with stiffness in the legs, the reflexes of which were exaggerated, and ankle clonus could be obtained. The patient also became colour blind, and there was contraction of the field of vision. The illness had lasted from three to four months, when gradually first one symptom and then another disappeared. Now this happened two years ago, and the patient was still well and performing her accustomed duties.—Dr. WILKS said that cases of organic disease of the central nervous system were treated by the usual remedies, and yet when one was cured, then we believed that the diagnosis was at fault.—Dr. BENNETT briefly replied.

Dr. SEYMOUR TAYLOR related the case of Arrested Rickets shown by him at the last meeting. The patient, aged six, came under notice in June, 1884. He is the twelfth child out of sixteen, and was born at term. His parents are healthy and temperate. His brothers and sisters enjoy good health, but two sisters are "knock-kneed." His mother dates his illness from a fall from his cot when a year and a half old. Subsequently he was treated by different practitioners for bronchitis and also "enlarged liver," and there was also at that time a history of laryngismus stridulus and profuse sweatings, especially about the head. The child now presents the typical pigeon breast, with beading of the sternal ends of the ribs. He has chronic bronchitis. The heart is depressed and pushed towards the right side. There is no cardiac murmur. He is stunted in growth; the limbs are shortened with marked curvatures of bones; he is "pot-bellied," and the spine is curved to the right; the fontanelles are closed; the frontal bone is "prow-shaped"; the girth at the occipital protuberance is 20¾ in. As regards the causation of the disease in this case, there is a remarkable absence of the recognised influences. He was born and reared in fairly healthy surroundings. His parents are healthy, but his mother has borne children very fast (sixteen in twenty-two years), but has had no premature nor stillborn children. This child is the only weakly one in the family. The injury to the child from a fall is interesting, as showing what may be the starting point of the disease in a child predisposed to rickets.—Mr. R. W. PARKER thought that there was no doubt that a large percentage of rickets became arrested, and it was not uncommon for all traces of the disease to disappear. It occurred to him to ask whether this case was one of arrested rickets. The extreme stunting and deformity at such an age seemed to him to point to the conclusion that a dyscrasia was still present, and he suggested seaside treatment, with systematic shampooing and gymnastics.—Dr. CHARTERS SYMONDS said that the case seemed to him to be one rather of continued than arrested rickets. He referred to a case of juvenile osteomalacia, which Mr. Davies-Colley had placed on record, and which somewhat resembled the present one.—Dr. ANGEL MONEY thought a paper by Dr. J. S. Bury of Manchester, on Osteomalacia in Rickets, had not received the attention it deserved. It was read at the British Medical Association in July, 1883.—Dr. SEYMOUR TAYLOR said that the patient had been treated by gymnastics and shampooing, and he hoped to continue this mode of treatment systematically.

Dr. CHARTERS J. SYMONDS read a paper on a case of Nephro-lithotomy. It was that of a man, aged fifty, who had suffered for twenty-four years from left renal colic. The attacks occurred at varying intervals, and lasted from a day to a week. During the last four years this pain had nearly left him, and his health improved. Seven months ago micturition became frequent, and three months later blood appeared in the urine, in amount sufficient at times to obstruct the urethra by the coagula. Blood generally appeared after working, particularly gardening, and he had a dull pain in the left loin. No tumour could be felt. The case being under Dr. Mahomed's care, Dr. Symonds was called to see him, and it was decided to cut down on the left kidney. This was done on July 11th, 1883, the incision being parallel and close to the last rib. The lower end of the kidney was first isolated, and at once a stone was felt fixed in the commencement of the ureter. The tissues were scratched through with a director, but on enlarging the opening the stone fell back into the pelvis of the kidney, which was greatly dilated. Finally the cortex was cut into, the finger introduced, and the stone removed. Very little bleeding followed. The operation was performed antiseptically, and by the 20th the wound had entirely closed. Attention was directed to the importance of isolating the lower end of the kidney first and examining from the anterior surface, in the way pointed out by Mr. Howse; also to the rapid union which followed, notwithstanding the amount of injury inflicted upon the kidney. In the subsequent history of the case, it was stated that six months after there still remained some blood in the urine, that the pain still continued to some extent, and it was feared that a calculus existed in the other kidney. When last heard of, Nov. 10th, 1884, the man was free from pain except when he overexerted himself. The urine contained pus and some blood.

Mr. HENRY MORRIS read a paper on a case of Nephro-lithotomy. The patient, aged twenty-four, a jeweller, was admitted under Dr. Powell into the Middlesex Hospital on April 10th, 1884, suffering from symptoms of calculus in the left kidney. Since his schoolboy days he had complained of pains in his loins, but in spite of this he had enjoyed fairly good health until about two years ago, when he was attacked by "kidney complaint." This came on without any assignable cause, and was chiefly marked by pains in the left loin, shooting down at times to his left testicle. For three weeks before admission these pains had been too severe to permit of his working, and he attended during this period at the out-patient department. On admission he had pain in his left renal region, and tenderness on deep pressure in the left loin. His urine was neutral, of sp. gr. 1010, and contained blood and triple phosphates. There was frequency of micturition, though the urine was stated to be somewhat deficient in quantity. Five days after admission, however, it was noted that the average daily quantity of urine voided had been forty-five ounces. From April 10th to 25th the pain was diminished and inconstant; but there was still tenderness on deep pressure in the left lumbar region. When the pain occurred there was retraction of the testis. Moreover, the left testis was discovered to be much atrophied. The urine at this time was acid, sp. gr. 1024, and contained a trace of albumen due to the presence of pus. Nephro-lithotomy was performed on May 10th, 1884. A calculus was felt by the finger on the front of the kidney near the inner border and below the hilus. Digital examination of the posterior surface and acupuncture of the kidney had previously failed to detect it. The sensation communicated to the finger by the calculus through the renal substance was simply that of increased induration, as compared with the resistance offered by the rest of the kidney. With his finger-nail Mr. Morris scratched through the renal tissue covering the calculus, and thus verified the nature of the induration; then with a bistoury he incised the inner free edge from the posterior surface, and partly by pushing the calculus with the left index finger (which was kept all the while in front of the kidney) and partly by the aid of a narrow curette the stone was dislodged and removed. There was no hæmorrhage of any moment from first to last. A large drainage-tube was introduced into the wound, but not into the kidney; the edges of the wound were held together by sutures; and terebene oil on lint and a thick layer on cotton-wool were retained over the wound by a tight bandage. The operation was performed at 2 P.M. At 1 P.M. he had micturated for the last time before the operation, and no urine was passed, after the operation, by the penis until 7.30 A.M., on May 11th, when fifteen ounces of lightly blood-stained urine were voided naturally. At noon on the same day (May 11th) nine ounces more were voided, so that twenty-four ounces were passed naturally in the first twenty-four hours after the operation. The dressings were changed once in the evening of the day of operation, and three times on the following day, but on May 12th there was so little discharge from the wound that this frequency of dressing was considered quite unnecessary. Urine had, in fact, ceased to pass by the wound. During the second period of twenty-four hours the urine was passed as follows:—May 11th: 2.50 P.M., 4 oz.; 5 P.M., 4 oz.; 10 P.M., 4 oz. — 12th: 12.15 P.M., 5 oz.; 2 A.M., 4 oz.; 5.15 A.M. 6 oz.; 7.50 A.M., 10 oz.; 10.45 A.M., 6 oz.; 1.21 P.M., 5 oz. Making a total of 48 oz. The urine voided continued to be blood-stained until May 14th. On the 15th it was neither blood-stained nor did it contain albumen. Its specific gravity was 1023, and there were 40 oz. voided in twenty-four hours. On the 16th the quantity of urea was estimated, and found to be 495 gr. in 42 oz. passed in twenty-four hours. On May 17th the wound was in great part united, and the stitches were removed. The patient had had no pain since the operation, and his only discomfort had been the enforced detention in the recumbent position. On May 20th the bowels had not acted since the operation, and so an enema was given. This had the desired effect, and the defecation was unattended by pain; but on May 21st, from the state of the dressing, it was inferred that a little urine had again been discharged through the torn wound. The temperature rose on this day to over 101°, 101·8° being the highest. On the following day, the 18th, and on part of the 19th, the temperature remained just below 100°. With these exceptions the temperature throughout never exceeded 99° F. Sixty ounces of urine were passed per urethram, so that the chief part, if not the whole, of the urine from the left, as well as the right, kidney, must have come the proper way. On the 23rd the bowels again acted twice, and again a small quantity of urine was thought to have come subsequently through the wound, but the amount so escaping was extremely small.

It would seem as if the passage of the fæces along the descending colon caused some disturbance to the wound in the kidney, which, however, must have nearly healed. This interference was the less improbable owing to the situation of the wound in the kidney. Forty-six ounces of urine were passed the natural way; it was of good colour, sp. gr. 1027, acid, and contained no albumen. On May 28th the patient, who had been on ordinary diet since the 26th, was feeling quite well, and only the track of the drainage-tube remained unhealed. On June 3rd this track had closed, so that not even a fine tube could be introduced. On June 10th he got up for the first time. On June 12th he went into the garden and there took walking exercise. He continued to gain strength daily, and was considered to be well, when on June 25th, at 8 P.M., after taking a good deal of exercise outdoors, he passed urine coloured deeply with blood. At 4.30 A.M. on June 27th the urine was still more blood-stained than that passed at eight the previous evening. At 9 A.M., June 27th, the urine was much less mixed with blood, and on June 28th 51 oz. of urine were passed in twenty-four hours: it was acid and of sp. gr. 1020, and contained neither blood nor albumen. The bowels had been acting twice a day, so that the hæmorrhage could not have been due to pressure on the kidney by an overloaded colon. No pain, sense of discomfort, or feeling of illness of any sort, attended this attack of hæmaturia. For a few days he was kept in bed, but there was no return of the hæmaturia, and on July 8th he left the hospital quite well and with the cicatrix in his loin throughout perfectly firm. On several occasions since (the last being Jan., 1885) he has been seen at the hospital. He has had no return of the hæmaturia, never suffers pain, has been at work regularly since leaving the hospital, and has never felt better in his life than now. The calculus consisted of a nucleus of oxalate of lime coated first with urate of ammonia, and outside this with oxalate of lime again.—Mr. BARWELL thought that it would have been better if the kidney had been removed at the time of the operation in Dr. Symonds's case, for the kidney was evidently considerably diseased. He did not think that the danger would have been increased by nephrectomy. He did not think that the other kidney should be inspected, at any rate until an estimate of the amount of urea discharged had been estimated.—Dr. CHARTERS SYMONDS said that though the kidney was practically useless, nevertheless it was merely atrophied from pressure; and, as no active disease was present, he decided to leave it.

Mr. Morrant Baker showed a living specimen of Floating Kidney in a Man.

MEDICAL SOCIETY OF LONDON.

Annual General Meeting.—Diet in the Febrile State.

THE annual general meeting of this Society was held on Monday last, Mr. Arthur E. Durham, F.R.C.S., President, in the chair.

Mr. A. P. GOULD read the report of the Council, which congratulated the meeting upon the prosperity which has marked the one hundred and twelfth year of the Society's existence. The Proceedings of the Society would continue to be published annually. Only one essay had been received in competition for the Fothergillian medal, and the adjudicators had not yet completed their report. The financial position of the Society had been materially improved.

The report of the hon. librarian, Dr. ALLCHIN, stated that upwards of 2500 volumes on the subjects of Anatomy, Physiology, Medicine, Surgery, and Midwifery had been repaired and catalogued and placed in their respective sections for easy reference.

The adoption of the reports was moved by Dr. SEWELL, seconded by Mr. DAVY, and carried.

Sir JOSEPH FAYRER moved a vote of thanks to the retiring President, which was seconded by Mr. GOODSALL, and duly acknowledged by Mr. DURHAM.

A vote of thanks to Dr. Wiltshire on retiring from the position of honorary treasurer, the duties of which he had discharged during a very anxious period, was proposed by Dr. THEODORE WILLIAMS, and seconded by Dr. WALTER SMITH. After a vote of thanks to the retiring vice-presidents and members of Council had been carried, a similar vote to the retiring honorary secretary, Mr. Pearce Gould, was put and carried by acclamation.

Dr. ALLCHIN read a paper on Diet in the Febrile State, which appears in full on another page.—Dr. ROUTH advocated the use of inunction to check cutaneous respiration and so diminish the pyrexia. As to diet, he strongly recommended raw beef-juice, made with tepid water, which was very easily absorbed; he estimated that three claret wine-glasses were equivalent to a mutton chop. He agreed with Dr. Allchin in recommending fats, especially cod-liver oil, in fever to supply the waste of hydrocarbon.—Dr. DE HAVILLAND HALL regretted the absence of practical observations drawn from Dr. Allchin's experience. Dr. Dupré had provided an excellent practical recipe for the beef-tea or beef-juice recommended by Liebig. Take one pound of meat and one pint of distilled water, from two to four minims of hydrochloric acid, and from fifty to ninety grains of common salt. The meat must be finely minced and soaked in water for one hour; the fluid was then to be strained through a fine sieve without pressure, and the filtrate made up to one pint. The whole of the albumen was thus extracted.—Dr. T. H. GREEN thought Dr. Allchin's paper gave an excellent *résumé* of the physiology of diet.—Dr. PARAMORE made some remarks on the value of various articles of diet which might be used either as food for children or in fever.—Dr. ALLCHIN, in reply, said that he had specially advocated the use of partially-digested amyloid foods.

Reviews and Notices of Books.

A Practical Treatise on Urinary and Renal Diseases. By W. ROBERTS, M.D., F.R.S., Professor of Medicine at the Victoria University, and Consulting Physician to the Manchester Royal Infirmary; assisted by R. MAGUIRE, M.D. Lond. Fourth Edition. London: Smith, Elder, and Co. 1885.

TWENTY years have nearly elapsed since the first edition of Dr. Roberts' work on Renal and Urinary Diseases was brought under the notice of the profession, and during that period it has undoubtedly held a foremost position among works on the same subject, both as a text-book for the student and as a practical work of reference for the practitioner. The cause of its great success lay both in its comprehensiveness and conciseness. Other works, indeed, were before the profession, but they either dealt with part only of the subject or else were too diffuse for practical purposes. Another attractive feature of Dr. Roberts' treatise was its eminently clinical character and the graphic manner in which the essential features of the disease under consideration were portrayed. The third edition of the work has now been exhausted for some years, and hitherto Dr. Roberts, for want of leisure, has been unable to undertake the preparation of a fourth; but, having obtained the assistance of Dr. Maguire, he has at length been able to accomplish it. The task must have been no slight one, for during the few years that have elapsed since the appearance of the last edition our knowledge with regard to renal and urinary pathology and physiology has extended so enormously that nearly the whole of the subject matter of the work required to be either revised or entirely rewritten. In many points the authors have succeeded in this difficult task, but at the same time we must confess to some disappointment that the work does not always keep itself quite in touch with existing views. This, no doubt, is occasioned by a natural desire to keep to the old lines as much as possible whilst importing new material; but this has resulted in places in a want of harmony between the new and the old.

The opening chapters, describing the Physical Properties and Chemical Constituents of the Urine, together with the methods of examining that fluid, are excellently arranged, and are full of information. In the section describing the colouring matter of the urine we find the interesting observations of Dr. Maguire, on the occurrence of certain urines which become brown on exposure, owing to the presence of pyrocatechin, which he believes to be identical with Bödecker's alkapton. Speaking of the presence of bile acids in the urine, he mentions only Harley's view that they are charac-

teristic of jaundice from obstruction, and does not mention the fact that they are constantly present in small quantities in normal urine, nor the view, now generally accepted, that bile acids are found only in the earlier stages of all forms of jaundice, and that they disappear as the destruction of the liver tissue proceeds. With respect to the physiological variations in the reaction of urine, Dr. Roberts still considers that the "alkaline tide" is caused by the preponderance of alkaline bases taken in as food. Though this may possibly explain its occurrence after a meal, it altogether fails to account for it when no food is taken, such as after cold bathing, &c. Dr. Roberts does not believe "that there is any constitutional state specially characterised by an excessive elimination of phosphates." Although undoubtedly in a considerable number of cases the so-called "phosphatic diathesis" is nothing more than a deposit of earthy phosphates, without any excessive elimination, still there are many well-authenticated cases on record which show that the total amount of phosphoric acid excreted daily may be increased considerably, out of proportion to the other urinary constituents, and which can only be accounted for on the supposition that there is increased metabolism of the phosphorus-yielding tissues. No mention is made of the occurrence of partially oxidised phosphorus in urine, in the form of glycerin-phosphoric acid, protagon, or lecithin; it has, however, been found in the urines of patients suffering from various nervous disorders, diabetes mellitus, and phthisis.

In the chapter on Micro-organisms in the Urine, Dr. Roberts, in addition to the usual forms, describes an organism he met with in the form of beaded threads, or micrococcic chains, in freshly passed undecomposed urine. He has never met with a similar case, and, on account of its rarity, believes the parasite to be of exotic origin. As the patient had resided some years previously in South America, this opinion is likely to be correct.

The chapter on Diabetes, both insipid and saccharine, is characterised by the author's usual clinical insight. We must demur, however, to the statement that the classification of the former into a disorder characterised by a profuse discharge of water without an increase in the amount of solids, and into another characterised by only a moderate discharge of water but an excessive elimination of solids, is "valueless in practice" or difficult to determine. Surely there must be a vast distinction between the mere draining off of water unattended with any definite increase of solids, and those cases in which the solid matters are doubled and trebled. In the one instance the hydruria is caused by mere increase of pressure in the capillaries of the kidneys under vaso-motor influence; in the other the drain of solid matters is occasioned by increased metabolism throughout the body generally. Nor is the difficulty in the way of recognising the condition so stupendous as Dr. Roberts imagines; the collection of the twenty-four hours' urine once a week and the determination of the specific gravity of the collected urine being all that is required. With regard to diabetes mellitus, we must express a somewhat similar regret that the distinction between the more permanent forms of diabetes and those in which sugar appears as a more or less fleeting symptom is not more clearly defined. In this we think the suggestion originally made by Dr. Lauder Brunton extremely valuable—viz., to restrict the term diabetes to the more permanent forms, whether mild or severe, whilst the purely symptomatic forms should be simply referred to as glycosuria. Again, with regard to the unity or multiformity of Bright's disease, we fancy the statement that the belief in the multiformity of the disease has "steadily gained ground" in this country will be received with considerable reserve; certainly it is not borne out by reference to the recent contributions of younger pathologists. Dr. Roberts still includes the waxy kidney among the many forms of chronic Bright's disease, though he admits that many pathologists now distinguish between it and the changes resulting from diffuse inflammation.

The chapter devoted to Suppurative Inflammations is perhaps the least satisfactory in the work, and yet within the last few years it has been much discussed and made the subject of extensive research. Little allusion is made to perinephritis. The valuable investigations of Mr. Marcus Beck (published in 1879) into the pathological conditions that give rise to "surgical kidney," or, as he terms it, consecutive nephritis, are dismissed in a foot-note. This is hardly a fair recognition of what perhaps may be considered one of the best contributions to original pathological research, published during the last five years, and one which has done so much to throw light on this difficult question. Mr. Beck's work is now generally recognised. Mr. Doran, in his recent volume on Diseases of the Ovaries, &c., has pointed out how frequently the morbid conditions noticed by Mr. Beck are found in the kidney after death from operations on the internal genital organs. This observation, taken in conjunction with the fact communicated by Dr. Matthews Duncan, that albuminuria is frequently associated with parametritis (a communication which Dr. Roberts has overlooked), seems to show a probable connexion between the kidneys and the internal genital organs. This connexion, which Dr. Matthews Duncan considers to have reference to embryonic development, may probably be due to communication through the lymphatics, a supposition which the recent researches of Dr. Steven of Glasgow render extremely probable. Finally, we imagine surgeons will dissent from the opinion that the question of the removal of the kidney in unilateral pyonephrosis must still "be considered *sub judice*."

In bringing our remarks to a conclusion, we would observe that our criticism has been made in no adverse spirit. The present edition deserves all the praise that we have already bestowed on previous issues of the work, but we have felt that a systematic and representative treatise of this kind should adequately represent the views held by the working pathologists of the day. We do not say that their views should be adopted, but they are certainly deserving of more recognition and criticism than have been accorded them in the volume before us.

In War Time. By WEIR MITCHELL. Boston: Houghton, Mifflin, and Co. 1885.

Charley Kingston's Aunt. By "PEN OLIVER." London: Macmillan and Co. 1885.

IT cannot be doubted that success in our profession is not unfrequently due to the possession of powers of exposition above the ordinary. We have known men to owe their position, both in the profession and outside it, almost solely to their mastery of the English language. It would perhaps be going too far to say that success is impossible without the possession of the literary faculty, but it is certain that where this power is combined with fair intellectual abilities success is sure to come sooner or later. Dr. Weir Mitchell is known to the profession at large as a man of unusual mental capacity, endowed with the powers of original research and literary expression in a remarkable degree. As a work of shrewd observation and sound inference his first essay in prose is a thorough model. The true physician ought to have the gift of clear insight into the nature of men and things; he should be able to penetrate the thin coating of veneer which civilisation has developed as an exoskeleton about the hearts of men. Even where civilisation exists in its earliest dawn, as amongst savages living in tribes, the heart is invested with a thin covering which mostly takes the shape of artfulness, and is easy to dismantle. The most prominent character in Dr. Weir Mitchell's novel is that of

Dr. Wendell, for whom one can but have the heartiest contempt, notwithstanding that he manages to engage the serious affections of Mrs. Alice Westerley, a creation with which we are in love, and a few specimens of which we believe we are acquainted with in actual life. Dr. Wendell is presented as capable in a measure of high intellectual abilities, but utterly wanting in any of those traits which deservedly call forth our admiration and sympathy; he is a weak-backed, insignificant piece of human nature, which we would fain believe is not represented in the ranks of the medical profession of to-day; of courage he has none; of instability he is a perfect example; his powers of application are of the feeblest. Blest with extraordinary powers of taste for colour, form, and music, his is a gentle intellectuality, totally unfit to cope with the serious business of the medical profession. Indeed, as the author says, "it seems probable that he should never have been a doctor at all." The novel is decidedly interesting; its dramatic features are good; the plot is not very strong, but the interest in the story seldom flags; the conversation is for the most part natural, the sentiments are of the refined orthodox order, and the language, though occasionally savouring a little too much of poetic licence, is taken from the well of English undefiled. "Where the barren soil seemed to give back no least return" reads more like a line of verse than of prose.

The interest of "Charley Kingston's Aunt" is of a rather more exciting kind than that of the tale above noticed. We think "Charley Kingston's Aunt" will be widely read, not as a serious literary attempt, but as an attractive story of the lighter kind. There is nothing improbable in the plot, and the story is well narrated. Besides the incident—in the dissecting-room—on which the novel hangs, there is scarcely more than a little by-play in the form of a love-chase, the course of which runs fairly smoothly. The novel might be compared to a star company at a theatre or to one of Doré's pictures, where the central figure is everything, and where the setting simply serves as a foil to the principal character. In this respect it contrasts with Dr. Weir Mitchell's narrative, which abounds in skilful delineation of character.

ARMY ESTIMATES.

IN the army estimates which have just been published the sum required to defray the "expense of the medical establishment and services" is stated as £320,960. In the estimates for 1884-85 it was only £303,000, but a sum of £15,000 was provided in a supplementary estimate on account of the war in the Soudan, thus raising the total to £318,000. The increase for the coming year, therefore, is only £2960, but as there is shown a decrease of £6000 in the charge for militia surgeons and civilian medical practitioners, the increase would be more correctly stated at about £9000. A considerable portion of this increase, however, is due to the transfer to the medical vote of the officers of the Medical Staff Corps, formerly included under the vote for regimental pay. The estimates show an increase in the *personnel* of the medical staff of twenty-four executive officers and a decrease of four acting medical officers and of two apothecaries; the number of administrative officers remains unchanged. The strength of the department, exclusive of the officers employed in India, will be 1 director-general, 7 surgeons-general, 20 deputy surgeons-general, 51 brigade surgeons, surgeons-major and surgeons, 52 acting medical officers, and 1 apothecary. For the pay and allowances of these officers, and including surgeons on probation at Netley, the sum of £245,065 is required. A further sum of £4000 is taken for the pay of civilian medical practitioners and medical bills, of which £380 are for colonial stations and the rest for home districts. The Army Medical School at Netley requires £7268, but this includes an "allowance to the examiners of candidates for the medical service" of £700. For the Army Sanitary Committee £1150 are taken, being the same amount as in previous years. The strength of the Medical Staff Corps is stated at forty-nine officers and 2400 non-commissioned officers and men. The sum estimated for their pay and allowances is £87,955; in addition to this there is a charge of £25,500 for departmental and extra duty pay. For pay of nurses, extra duty pay of regimental hospital orderlies, and miscellaneous labour £8650 are required, but we cannot find any statement of the number of nurses included under this head. We are glad to observe that it is intended to continue the instruction of the men of the medical staff corps in hospital cookery, £550 being taken for the pay and allowances of civilian instructors. The estimate for medicines, &c., amounts to £25,000, being £2000 above that of the preceding year. The number of medical officers on half-pay eligible for employment is very small, amounting only to eight, of whom one is an administrative officer and seven are executive officers. On the retired list the numbers are 407, and the estimated amount required is £160,000. There are 258 widows of medical officers in receipt of pensions, and fourteen medical officers receive £100 per annum, each as reward for distinguished or meritorious services; in the list of the latter no change has occurred during the past year.

NAVY ESTIMATES.

THE sum which appears in the Navy Estimates under the head of medical establishments at home and abroad amounts to £67,650, being only £200 in excess of that for 1884-5; for medicines and medical stores £80,810 are required, being £2490 more than in the preceding year. As we have pointed out on previous occasions, these sums are very misleading, since the first does not include the pay of medical officers afloat, and the second comprises many things which are certainly miscalled medical. So far as we can ascertain from the Estimates, in their peculiar form, the *personnel* of the department to be provided for consists of 1 director-general, 2 inspectors-general, 10 deputy inspectors-general, 72 fleet surgeons, 75 staff surgeons, and 187 surgeons. A sum of £415 is allowed for the expenses connected with the examination of candidates, and allowances of £150 to one of the fleet surgeons and £50 to one of the surgeons at Haslar Hospital are granted "for duties in connexion with the medical course of instruction,"—the miserable substitute for the course of which the young officers formerly had the advantage at Netley. An allowance of £50 is also given to one of the surgeons for "instructing boys training for Sick Berth Staff." In connexion with this we are much pleased to see that the promised introduction of female nursing into the naval hospitals has taken place. At Haslar Hospital one head sister and eight sisters, and at Plymouth Hospital one head sister and five sisters, are now placed on the establishment, and a sum of £410 is put down for providing accommodation for the female nursing staff at Haslar. On the half-pay list there are 33 officers who are liable to be called upon to serve. The retired list has 21 inspectors-general, 70 deputy inspectors-general, 66 fleet surgeons, 71 staff surgeons, and 40 surgeons, and there are 243 widows of medical officers in receipt of pensions. We are glad to observe that sanitary works have not been quite overlooked, for under that head the following charges appear fairly to come:—At Chatham Dockyard £500 for boring for water-supply, at Pembroke Dock £1800 for fresh water reservoir, at Bermuda £1100 for sanitary improvements, at Haslar £2500 for hospital kitchen, at Forton Barracks £1200 for a new swimming bath, and at Walmer £250 for new latrines in drill field.

THE TOKIO MEDICAL LIBRARY AND MUSEUM.—In order to hasten the coming of the time when Japan may begin, in a measure, to repay the debt she owes to the Western World for the wealth of learning made available to her, it has been decided to establish a library in Tokio, in which may be found the principal foreign and native publications relating to medicine. The library has been established under the auspices of the "Sei-I-Kwai," or Society for the Advancement of Medical Science in Japan, to encourage the more extensive reading of Western medical works, and to endeavour to raise the standard of medical literature by furnishing sources of reference now only available to very few.

THE LANCET.

LONDON: SATURDAY, MARCH 7, 1885.

WHILST almost every department of medical science has of late years been subjected to searching investigation and reform, Forensic Medicine has been sadly neglected. This is deeply to be regretted, since the application of medical knowledge to the administration of justice is one of the highest functions of the profession. Instead, however, of the medical witness being credited as the possessor of an enviable position, he is too often regarded as an object of suspicion. The cause of this is not far to seek. In civil trials especially it is customary for the litigants on each side to be supported by doctors of their own selection, and, as everyone knows, the latter are frequently so imperfectly informed of the facts that they only become conversant with the merits of the case when under the lash of the cross-examiner, and when it is too late to withdraw unconditionally from a position, however untenable, without loss of prestige. The fault lies rather with the system than with its supporters and exponents. Many a medical man has entered the witness-box with the strongest determination to "speak by the card," and consistently with the terms of the oath he has taken, but has left it disgusted with himself and discredited by others. He is led into deep water by the contentions of opposing counsel, and bewildered by the "legal jargon" let fall as a cloud before him. The natural remedy for this blot on our judicial procedure lies in the appointment of medical assessors to assist the presiding judge in adjusting the balance between contending suitors. If such a practice were instituted it would inevitably diminish the number of vexatious actions—actions brought on the chance of a verdict being obtained through the misunderstanding or sympathies of a jury. The medical witnesses would rest secure in the support of a competent and disinterested arbitrator, and there would be less temptation to "rising young witnesses" to seek the favour of wealthy but unscrupulous clients. Moreover, legal medicine in its administrative aspect would be freed from the stigma that rests upon it, and physicians and surgeons would not feel, on taking part in a "trial for damages," that they were placing their reputation in jeopardy. The difficulty as regards the payment of an assessor in civil actions might be got over by an enactment that his fee should be included in the "costs" in the case, and, like the other charges, be subject to taxation. What has been said in reference to the procedure in the equity and common law courts applies with double force to criminal trials, in which something more than the professional morality of the medical jurist is concerned. Here the liberty of the subject is at stake and public opinion widely exercised. Surely, if it is not derogatory to the status of the judge in the Admiralty Court to be assisted by Trinity brethren, there can be no objection to an assessor at a tribunal where questions based upon the most inexact of sciences, and one that requires special and extensive knowledge to interpret, are raised. Our continental neighbours are ahead of us in this matter; but then legal reform in this country is painfully slow and half-hearted.

But of greater interest to the practitioner of medicine than his relations to the High Court of Justice is the position he holds with respect to coroners' inquests—of greater interest because, whilst he may be called upon only once, perhaps, in his professional career to give evidence in one of the superior courts, he is practically certain to take part in many an inquiry as to "when, where, and by what means" a certain individual came by his death. A great deal has been written, and many suggestions have been made, upon the desirability of experts being appointed and attached to the office of coroner in order that that official may have the assistance and guidance obtainable only from those specially learned in pathological science and medico-legal practice. There is something to be said in favour of the proposal, yet nevertheless it is a question beset with dangers, against which it would be absolutely necessary to provide efficient safeguards. In the majority of cases the general practitioner is perfectly competent to conduct a post-mortem examination, and to bring the requisite knowledge to the interpretation of his observations. The privileges conferred upon him by his diploma and the Coroners Act are not to be assailed with impunity; and although we freely admit that in cases of unusual complexity, especially where the fate of a fellow-creature is involved, it would be wise to have a second opinion in order that one might serve as a check upon the other, and the responsibility be divided, we hold that any attempt to supplant the ordinary medical witness by an expert would be dangerous in principle and ruinous in practice. It is quite true that forensic medicine as an experimental art is all but ignored in our schools, as shown by the superficiality of the acquirements of candidates presenting themselves before the examining boards. At the same time it is equally clear that a student learns most of what is useful to him in professional life, not from attending lectures on theoretical or constructive cases, but by actual experience of the difficulties inseparable from an investigation which embraces not only medicine proper, but many cognate sciences. We do not hesitate to say that jurisprudence, instead of being practically taught at our colleges, is treated as though it were an ornamental appanage to medical education. It may be argued that classes in toxicology are conducted with a view to furnishing the student with knowledge that will serve him in good stead when he enters on the active exercise of his profession. So far it is a praiseworthy undertaking, but when we consider how comparatively small a part toxicology plays in the inquiries before a coroner's jury, and that for this particular branch of forensic medicine special provision has been made by the appointment of Government analysts, it is obvious that our present code of instruction only touches the fringe of a subject included in the prescribed curriculum of study. We would suggest that, whenever possible, medico-legal investigations, including an examination of the body, should be held at our hospital schools; and further, that ordinary post-mortem examinations should be conducted as though they were the bases of official inquiry, and not made merely for the purpose of illustrating some point in transcendental pathology.

To return to the question of the advisability of appointing

medical experts as assessors to coroners' courts, we repeat that there can be no objection to such a course, provided that the rights of the general practitioner are not curtailed. The system should be permissive, not compulsory. If a medical man, for instance, is requested to make a post-mortem examination of a body dead of some infectious disease, and at the same time he is likely to be summoned to a case of midwifery, then it is obvious that it would be to the advantage of all parties that he should have the assistance of a colleague upon whose attendance he could rely. Again, it might happen that in a particular instance he might not feel justified in formulating his opinion for presentment before the coroner's court without confirmation by one specially versed in the subject. It would save time—an important element in medico-legal inquiries—if, instead of referring the matter to the coroner he were empowered to consult at once an authority appointed for the purpose. It should be a matter of mutual understanding that the coroner should not in the first instance commission the expert to assist in making the inquiry except in cases of urgency or difficulty. It would be reasonable for the general practitioner to give one half the fee to the expert whenever he requested his services, and for the coroner to be responsible for the remuneration of the expert, without making any deduction from the fee of the general practitioner whenever he ordered the former to serve as an additional witness.

THOSE excellent people who are made unhappy by hearing—as we hear far too often—from the pulpit of the hostility of science to religion should really be a little less fearful. Their fears do not seem to be shared by the best members of every section of the Church. Only the other day we reported a very valuable contribution to science by Dr. DALLINGER, a Wesleyan minister, in the shape of the discovery of a new septic organism, with a description of its habits and history, which would have done honour to PASTEUR, or KOCH, or CHEYNE. The whole press has recently been eloquent in praise of the Bampton Lectures of the new Bishop of London, and we desire to-day to take our share in the recognition of this great service, as one of deep interest to that large section of scientific men who are not vain enough to doubt that there are many facts, and possibly some forces, in the universe not yet included in their philosophy, and that there exists behind all these facts and forces a great essential Being whose Will preceded and continues to dominate all physical laws, and whose deity is only confirmed by His own eternal recognition of moral law. It would indeed be a pitiable thing for the human race, even in its most gifted members—its NEWTONS, and HARVEYS, and DARWINS,—if it were to lose the conviction, hitherto so strong in the greatest minds—that there is such a Being, compared with whom our wisdom shows as foolishness and our keenest glances into the mysteries of life and nature are but as blind gropings. It is only fair to many even of the most sceptical scientists to admit that they display no jaunty irreverence, no deep satisfaction with their cold scientific conclusions, and that they are quite ready to believe that intelligence and conscience have not reached their consummation within the bounds of their nature.

The Bampton Lectures of Dr. TEMPLE[1] illustrate, in our opinion, the attitude which Christian men should assume towards science and those who promote it. He is no friend to religion who thinks to promote it by denouncing and discouraging science. Science "falsely so called" is contemptible. But every ascertained fact about matter, animate or inanimate, from the smallest particle up to the largest sun, is a real gain that should excite the gratitude of all men, and that must ultimately increase our advantage, as well as our admiration for Him who preceded all and dominates all.

Dr. TEMPLE is by no means the first eminent Christian who sees no enemy in science, and who can regard its most far-reaching discoveries with equanimity. But he is entitled to the credit of having, in the Bampton Lectures of 1884, taken in hand with equal boldness and candour, and we may add piety, a consideration of the relations of religion and science as affected by the latest suggestions of the latter, especially that of Evolution. It would perhaps be premature to say that the theory of evolution is established in the sense that gravitation or the main conclusions of geology are established. There are yet gaps in the evidence, missing links in the chain; but Dr. TEMPLE is quite right in perceiving the steady set of scientific opinion in the direction of the theory of evolution, and with a wise sense of past errors on the part of religious men, who are always apt to be unnecessarily anxious about the "ark of GOD," he cautions them against repeating the error of those who in the first burst of light of the astronomical and geological sciences saw dangers to revelation. We commend the stately and well-sustained argument of the Bishop to the attention of all devout men, whether they ostensibly range themselves on the scientific side or on the religious. We are more than ever disposed to abolish this distinction, readily admitting that, as there is now more than ever on the part of religious teachers a disposition to look at religious dogmas in the full light of science, so there is in scientific men of the first eminence a devoutness and a reverence contrasting most happily with the flippancy of unbelievers in other times. We could have no finer illustration or justification of this remark than the language and spirit of Mr. KITCHEN PARKER in his recent admirable lectures as Hunterian Professor at the College of Surgeons, especially when alluding in terms of high praise to the Bampton Lectures of which we are now writing. Dr. TEMPLE maintains that the doctrine of evolution as held by the most authoritative biologists in no way invalidates the doctrine of Creation, or even that of Design as elaborated by PALEY; but, on the contrary, that it greatly magnifies both. There is nothing in the present discoveries of science to explain the beginning of Life or the beginning of that spiritual faculty in man, in virtue of which he distinguishes all over the world, with more or less clearness, between right and wrong. The doctrine of evolution throws back to a more remote past the creative acts, and reduces the frequency of the necessity for the intervention or the interference of the Creative Will; but it in no way contrives to do without this factor, and apart from the assumption of it has no account to give of the origin of life even in its humblest forms—to say nothing of that highest manifesta-

[1] Macmillan and Co., London.

tion of life, the faculty of Conscience. Dr. TEMPLE readily admits that much of recent science tells heavily upon many of the dogmas and formulæ in which men have tried to crystallise religious truth; but the dogmas of men are as different from the truth of GOD as a crystal is different from an organised cell. It is no part of Dr. TEMPLE'S task to maintain every article of faith which exacting men would impose on their fellow-men. He allows that different parts of the Bible appeal to us with varying degrees of power and effect, and that even different alleged *miracles* have very different degrees of authentication. The one "miracle" for which he sees clear, unmistakable, and sufficient evidence is the Resurrection. But while he thinks other miracles less effectually attested, he fully admits that the miraculous element in the New Testament cannot be excluded "without a complete surrender of the position taken by the first Christian teachers." Here we must leave these admirable lectures, not without a further expression of our obligation to Dr. TEMPLE for a worthy and well-sustained argument, that may well help religious and scientific men to regard each other with more mutual respect, and to try to see from each other's point of view.

THE prominence we have given to the subject of school hygiene for many years past has been slowly bearing fruit, and is now attracting sufficient public attention to bring forth leading articles in the lay press. The reports of "THE LANCET Sanitary Commission on Public Schools," issued several years ago, indicated the importance we attached to this subject. At that time we found ourselves beset by one great difficulty, as we do now; and that difficulty is the secrecy maintained by all the public schools in the country on the subject of health and sickness among the pupils. We ask, Is it expedient that this secrecy should be longer observed? Have not the parents of English schoolboys a right to such information as will enable them to judge of the relative merits of the different schools with respect to the general health of the boys? That our public schools differ much in this respect is well known. At one typhoid fever recurs term after term, at another diphtheria, at a third scarlatina, and at a fourth "blood-poisoning." The only information parents can obtain is for the most part such as may be written home by the boys, or which is communicated by tutors interested in the good repute of the school. There is indeed no sufficient information available upon which the English parent can form a judgment of the suitability of any particular school to the health requirements of his boy's constitution. The school has therefore to be selected at haphazard.

This state of things is eminently unsatisfactory to parents, and is oftentimes attended with permanent injury to the health of pupils, and in some cases with fatal results. Many of our public schools are in low-lying, damp localities. To send a boy with an inherited disposition to struma or its allied diseases to such institutions will weaken his constitutional powers and lessen the value of his life, and in some instances bring it to a premature end. The upper classes of this country are exceptionally prone to such diseases, and many families "die out" and become extinct from these inherited dispositions, which judicious tending during the period of growth and development would help to subdue or counteract. Sufficient thought is not given by the well-to-do classes of this country to the bearing of school life on the health of manhood; yet it is a subject which must grow more and more in importance with each generation. A parent in selecting a school for his child should not lose sight of the inherited tendency to certain maladies in his family, and schools which favour the development of such tendencies should be eschewed. Yet the information upon which a parent can judge in this case is very insufficient.

The masters of public schools make widely known their educational successes—the number of scholarships gained and the competitive examinations passed. These have a far more intimate relation to the health and physical vigour of the boys than parents and schoolmasters are disposed to believe. Health and success in a scholastic career are essentially correlative. If the locality of a school is such that lassitude and debility prevail among the boys as a result thereof, no amount of ardour in the masters can raise the scholarship of the school up to a fair average. There will be a deficiency not in honours alone, but in success at the ordinary competitive examinations for entrance into the army, navy, or other professions. A certain standard of health must be maintained, and this can only be accomplished under medical supervision and direction, with freedom of judgment and liberty of action. Between masters and doctors there always has been a clashing of authority, and while the position of one is dependent on the will of the other there can be no freedom of thought and action. Nothing short of the appointment of medical inspectors to all grades of schools, independent of all authority except that of the Local Government Board, and responsible to and acting with the authority of this department, can put this matter on a proper footing.

Annotations.

"Ne quid nimis."

THE ROYAL COLLEGE OF SURGEONS.

ON the 4th inst., on the invitation of the President of the College, a deputation of the Association of Fellows waited upon the Committee of Charters and Bye-laws to consider certain recommendations proposed by the Association to be included in the new Charter. The deputation consisted of Messrs. Pollock, Willett, Norton, Davy, Macnamara, Jessett, W. Barnes, Couper, Tweedy, and Morgan (sec.); and the members of the Committee by whom they were received were Sir J. Paget, Sir S. Wells, and Messrs. T. Smith, Marshall, Cadge, Holmes, Erichsen, Lund, Savory, and Cooper Forster. The conference lasted over two hours. Until the Committee has reported the result to the Council no decision can be arrived at. Whatever that decision may be, nothing but benefit to the College can ultimately accrue from a free and friendly interchange of views between the Council and the more active Fellows. Both parties may be credited with a sincere desire to promote the welfare of the College and enhance its dignity and importance. The problem is the reconciliation of two lines of policy.

THE PHYSIOLOGICAL ACTION OF COCAINE.

DR. HERMANN M. BIGGS of New York has recently published the results of an exhaustive inquiry into the physiological action of cocaine on the frog, his observations having reference more especially to the influence of the drug on the various organs and tissues of the body. The experiments, which were conducted under the direction of Professor Christiani in the physiological laboratory of Professor du Bois-Reymond at Berlin, are of considerable interest. The salt employed was the uncrystallisable hydrochlorate prepared by Merck of Darmstadt. The solutions were all made with water, and varied in strength from 1 to 4 per cent. In the first place it was noticed that in frogs where the 2 per cent. solution was applied to the skin of the leg or to the mucous membrane of the mouth, complete anæsthesia of the part was quickly produced. The action on the pupil was not constant, but usually a moderate degree of mydriasis resulted. When a small toxic dose, say, a fifteenth of a grain, is injected under the skin, there is at first no perceptible effect, with the exception, perhaps, of a short period of excitement, which is never very marked and is often absent. The frog soon becomes quiet, moves languidly when touched, and breathes with increased frequency. In a few minutes it becomes motionless, or moves only after considerable effort. There is loss of power in the extremities, and this appears earlier and is more marked in the hind limbs than in the front. In a short time these effects pass off, and in an hour or two the animal seems as well as ever. After the injection of what may be called a moderate dose, say, a sixth of a grain, more decided symptoms are produced, and at the end of seven or eight minutes the animal lies prone and makes no effort to move, even when stimulated freely. In from two to three hours there are signs of recovery, and in about five hours irritation produces characteristic clonic contractions. When large toxic doses are given to a frog—a third of a grain and upwards—the effects manifest themselves almost instantly. All the usual phenomena follow in rapid succession, and in a very marked form. In two or three minutes respiration is laboured, there is decided opisthotonos, the pupils are dilated, the heart's action is slow, and the reflexes are abolished, or at all events greatly diminished. The animal has an anxious expression, and in a few minutes lies motionless on the table. After some hours signs of returning life begin to show themselves, but it is many days before recovery is complete. After the exhibition of a lethal dose the heart continues to beat for twenty-four or thirty-six hours, and then stops in diastole. The action of cocaine on the heart and on respiration is well marked. In small doses it at first increases the number of respirations and then decreases them, but in larger quantities death ensues from paralysis of respiration. It has a depressant action, too, on the heart, reducing the force and frequency of its pulsations, and finally arresting it both auricles and ventricle—in diastole. The action on the nervous system is still more marked. Small doses increase the reflex irritability of the cord for a short time, but when larger doses are given the period of heightened reflexes is lessened, and is followed by a period of longer duration, in which they are decidedly diminished. It appears from the researches of B. von Aurep that small doses heighten the irritability of the sensory fibres, but exert no effect on the motor filaments. Large doses almost completely paralyse the sensory filaments, and diminish greatly the irritability of the motor. It is found that cocaine in one per cent. solution when applied directly to the nerve-trunks will, after a transient period of increased irritability, depress greatly, and finally paralyse the nerve. If a nerve muscle preparation be made from a frog after poisoning by cocaine, the irritability of the nerve is found to be much diminished, and the strength of current required to produce a muscular contraction is decidedly greater than in the case of the normal frog. Small doses given hypodermically have little effect on the excitability of the voluntary muscles, but large doses diminish their contractility very decidedly. The pulsations are shorter, slower, and more feeble, and muscular excitability is soon exhausted. Dr. Biggs thinks that from the local and constitutional effect of cocaine on the different organs and tissues it is highly probable that its general action is a purely local one, exercised on those parts for which it has a chemical affinity through the medium of the blood. He concludes as the result of his experiments that the use of cocaine is indicated both in tetanus and in strychnia poisoning.

EXPENDITURE AT HOMERTON HOSPITAL.

TROUBLE has for some time past been brewing as to the expenditure at Homerton Hospital, and a subcommittee appointed to investigate the matter has now reported on it. This committee finds that, on a sudden increase of stimulants being ordered for a certain ward, the wine in question was not consumed by the patients, that the officers' dietary has been profuse and exceptional, that from the committee downwards there has been a lack of adequate supervision and an apparent indifference to responsibility, and that although actual collusion has not been shown to have existed between officials, contractors, and others, yet the condition of affairs was favourable to such collusion. The report then went on to refer to Dr. Collie, and a hope was expressed that he would in the future prove himself as efficient an administrator as he has been a physician. A resolution was also passed requesting the Local Government Board to make further inquiry, and on this a rider was proposed by Mr. A. Pell, M.P., and carried, to the effect that the investigation had shown the unfitness of the present medical superintendent for the office he holds. With the facts before us we think this rider should not have been proposed. It was admitted that the inquiry, not having been on oath, needed to be supplemented by an official one, that Dr. Collie had in every instance contended he was justified in acting as he did as regards stimulants issued to patients, and that for fourteen years past he had rendered able services to the Board. We can fully endorse the opinion as to the respect in which Dr. Collie has been held as physician and medical administrator, and we hope that official inquiry may lead to the withdrawal of all that is implied in the rider. The question generally is, from an administrative point of view, very serious. The stimulants at Homerton are stated to have cost between £4000 and £5000 in six months, and during the course of the inquiry the chairman of the Hospital Committee, the clerk to the committee, and the steward of the hospital, resigned their respective positions.

PULMONARY DISEASES IN WILD ANIMALS.

THE progress which has been made during the past three or four years in comparative pathology is certainly of the most remarkable kind, and has been owing in a great degree to the activity and ability of Mr. J. B. Sutton. We have had occasion during former sessions of the Pathological Society to comment upon the work of this observer. At the last meeting of this Society Mr. Sutton contributed an elaborate paper which gave an account of the zoological distribution of certain forms of lung disease among wild animals. We have elsewhere given a full abstract of this important communication. The main conclusions which have been arrived at are two in number. First, it seems to have been completely proved that tuberculosis is by no means a common disease of wild animals dying in captivity.

Secondly, it would appear that lung disease, not of a tubercular kind, is very frequent amongst the group of animals under consideration. Primates, when they are brought to this country, excluding man, appear to suffer from bronchitis, atelectasis, and lobular pneumonia. Carnivora under similar conditions are exceedingly liable to double pleurisy, lobar pneumonia, and bronchitis; whilst ruminantia suffer from "Perlsucht" or "bovine tuberculosis," bronchitis, and "worm-bronchitis." Mr. Sutton believes, probably correctly, that the vicissitudes of the English climate as contrasted with the tropical climate, from which many of these animals come, are to be set down as the causes of these bronchial and pulmonary affections.

THE OUTBREAK OF SMALL-POX AT THE THREE COUNTIES ASYLUM.

THE report of Mr. Swain, medical superintendent of the above institution, to the Committee of Magistrates, on the recent severe outbreak of small-pox, affords interesting evidence with regard to vaccination. Fifty-six persons in all were attacked. Twenty-two had three or more vaccination marks: of these, twenty recovered and two died. Of twenty-four cases having less than three marks, nineteen recovered and five died. Of seven cases having no vaccination marks, one recovered and six died. Of three cases described as "not known," two recovered and one died. Another table (of which there are seven appended to the report) shows the "percentage of recoveries and deaths on the various conditions of vaccination." Of the cases having three or more marks, 90·9 per cent. recovered and 9·09 died; of those with less than three marks, 79·16 recovered and 20·83 died; while of those who had no marks only 14·28 per cent. recovered and 85·71 died. The outbreak, of which we gave an account in our issue of Jan. 17th, appears now to be at an end. To vaccination and immediate isolation of the cases the medical superintendent attributes in great measure the checking of so severe and general an outbreak.

NO MEDICAL EVIDENCE.

AN inquest was held at Clayton-le-Moors on Feb. 19th on the body of a woman aged forty-five years. It transpired that the deceased, who had been addicted to habits of intemperance, was picked up in the streets partially insensible, and conveyed home by a constable. The husband of the woman was in bed at the time, but refused to come downstairs to assist his wife, on the ground that he had done it too often. Some hours afterwards he discovered her in a helpless condition, and, calling in a neighbour to assist him, placed her on a sofa and went to bed again. In the morning she was dead, and signs of profuse hæmorrhage were seen on the floor of the lower room, but none on the stairs or in the bedroom. The police constable deposed that he found the skull broken at the back part. No medical evidence was taken, and the jury returned a verdict "that deceased had fallen backwards downstairs whilst in a drunken state, and received injuries that caused her death," and severely censured the husband for not attending to his wife. Now, although it seems probable that the woman was in a helpless state from intoxication, it is not absolutely certain that she was not suffering from apoplexy. There are too many cases on record in which the diagnoses of policemen have proved to be erroneous. Partial or complete insensibility is apt to be interpreted by the terms "drunk and incapable," and for this reason alone we contend that it was very desirable that a medical man should have been called at the inquest. If the deceased did not fall downstairs, the most probable alternative, as suggested by the coroner, was that she had been pushed down. On the latter hypothesis suspicion would naturally rest upon the husband. As regards this point we offer no opinion; but we contend that if ever there was a case in which it was desirable to have skilled advice it was here. Coroners are too apt to rely upon the evidence of policemen, who, however well intentioned, are scarcely the proper witnesses to testify to the nature of an attack of coma, or of a fracture of the skull. In the interests of all parties concerned it is much more satisfactory to have these attested by medical men. That the husband was to blame there can be no doubt. It was his duty to see that his wife was placed beyond the reach of a fatal accident; but in extenuation of his conduct it is just to add that long suffering had blunted his humanity and warped his sympathy. He stands acquitted of any graver offence by the verdict of the jury. At the same time, it would have been better had the evidence, strong as it was, been further strengthened by such testimony as would satisfy public feeling generally. We trust that the mode of procedure in the above case will not serve as a precedent in future inquiries.

DEATH FROM ELECTRICITY.

IN the course of a correspondence in the *Electrician* on personal safety and electric currents, Mr. Trotter, observing that the case of the unfortunate man who lost his life at the Health Exhibition by touching the dynamo was not taken down in shorthand by a reporter, but that the coroner made very full notes, mentions that there was "first a spasmodic contraction of the arms and chest—in fact, of the muscles in the path of the current, described by a gesture by the witness which corresponded exactly to that which is tolerably familiar to those who occasionally receive an accidental shock. The man fell away from the dynamo, collapsed, rolled over, and became unconscious. He was probably dead before he fell. A slight mucous foam appeared at the lips; the body speedily became discoloured. Rigor never set in; and this, coupled with the fact that the blood never coagulated, is in accordance with several authentic records. All the bloodvessels in the path of the current were highly congested, more so in the chest than in the back; the brain was normal, and the heart empty."

THE PEKING HOSPITAL.

THE hospital at Peking, which is under the medical supervision of Dr. John Dudgeon, appears to have been of much service to the Chinese of that city and its surroundings. As seems to be customary with hospitals generally, the funds are in a bad state, but this lack does not seem to have affected the good work done. From the report which has recently reached us, we find that the annual attendances at the hospital are about 20,000, of which number about 8000 are new patients. There has never been a large in-patient practice. Cases of suicide by opium poisoning are of very frequent occurrence. Law and custom make it almost impossible for the common people to purchase any of the other deadly poisons. Blindness is very prevalent in China, and is largely due to small-pox as well as to neglected ophthalmia of new-born children and adults. Congenital blindness is said to be very rare. The diseases due to the long-continued use of opium, such as diarrhœa, dysentery, and a papular affection of the skin, are both very common and almost incurable. Œsophageal stricture is not infrequent, and seems to result from excessive drinking of native spirits, which contain large quantities of fusel oil. "Harakiri" is the term applied to a form of self-destruction in which the individual rips his abdomen open from the pubes to the sternum. One such case in a man aged eighty came under treatment in 1882. The large wound, through which the omentum, though not the intestines, protruded, was sewn up, and the patient ultimately recovered. Several fatal cases of hydro-

phobia have occurred during the past few years, and rabies is very common among the dogs of Peking. The efforts to reclaim the victims of opium-smoking occupy much of the time and attention of the medical missionary. Amongst the curious superstitions of the Chinese the following one may be mentioned. During pregnancy the woman is supposed to have four eyes, and her husband is credited with a like number of visual organs. Under such circumstances the belief exists that the husband cannot perspire. A pregnant woman came one day to the hospital beseeching for some medicine to cause abortion, in order that her husband, who was in a fever, might be able to perspire. It was supposed that if perspiration could be induced his life would be saved.

"NON-COMBATANTS."

"RIFLE firing had ceased; and the doctors, who had shared with a courage and zeal beyond all praise in all the dangers of the day, had got a temporary hospital in order, and were each doing his utmost to alleviate the sufferings of our wounded. Surgeon-Major Fergusson, the principal medical officer, Surgeons Briggs, Parke, Dick, Maconochie, and others, with the regimental surgeons, worked untiringly through the night helping the wounded." This was at Abu Klea. A war correspondent is the witness. It is the same story all through: the doctors share "all the dangers," and yet, because they do not draw their swords and rush at the foe, they are pooh-poohed as "non-combatants." Happily, the cold recognition of medical services does not cool the courage of our brethren in arms, as we may perhaps, in a journal which is "only civilian," be permitted to call them.

BABY-FARMING IN FRANCE.

THOUGH the birth-rate in France cannot be increased by any Parliamentary enactment, legislation has certainly contrived to protect the lives of such children as are born. In December, 1874, the National Assembly adopted what is known as the "loi Roussel." The results already attained by this measure are most significant and encouraging. According to this law, all persons taking children to nurse are placed under the superintendence of the district prefect of police, assisted by the local authorities, medical inspectors, and committees of lady visitors. Statistics for the year 1883, relating to this work, have just been published; they show that in Paris and its suburbs 20,071 children were put out to nurse. Of this number no less than 15,520 were sent into the provinces; where, however, they also came under the Roussel law. Indeed, this enactment is becoming more and more popular, the nurses themselves finding it to their advantage to submit to its stipulations. Thus, while in 1881 the number of women who claimed official inspection amounted to about 17,000; this figure increased to more than 20,000 in 1883. Of the 4551 children that remained in the immediate neighbourhood of Paris, 2311 were given out to wet-nurses, 1582 were brought up with the bottle, and 558 were undergoing the process of weaning. Of the 414 children who died in 1883, 217 were fed from the bottle and 180 from the breast. Thus the mortality equalled 14 per cent. and 8 per cent. respectively. From 1880 to 1883 the total mortality of children put out to nurse had been reduced from 9·99 per cent. to 9·30 per cent. This improvement is due principally to medical inspection. The doctor attached to this service visits the home of the nurse, and also examines her personally. Of the 15,085 nurses examined in 1883, 355 were declared incapable of acting as wet-nurses, and compelled to content themselves with feeding by hand; while permission to nurse was absolutely refused to 33 applicants. Some improvement has also been realised in the sanitary condition of the homes where the children are kept, and here and there the permission to nurse has been withheld when the dwelling was considered exceptionally unwholesome. In this respect, however, the progress is not so marked. On the other hand, the fact that all persons who nurse infants other than their own are compelled to submit themselves and their homes to medical examination and superintendence has been the means of eradicating many injurious superstitions with respect to the rearing of children, and of spreading knowledge based on a scientific foundation. The French authorities seem, among other things, to have waged successful war against feeding-bottles with long tubes. These contrivances are rarely kept in a state of sufficient cleanliness, and the tubes are fouled long before the contents of the bottle show any signs of decomposition. Altogether, what has sometimes been termed baby-farming on this side of the Channel is rapidly becoming a profession in France offering certain State-regulated guarantees, and constantly imposing on its licensed members a higher standard of excellence.

POWERFUL REFRIGERANTS.

SOME experiments recently made by M. Olszewski appear to show that liquid oxygen is one of the best of refrigerants. He found that when liquefied oxygen was allowed to vaporise under the pressure of one atmosphere a temperature as low as −181·4° C. was produced. The temperature fell still further when the pressure on the liquid oxygen was reduced to nine millimetres of mercury. Though the pressure was reduced still further to four millimetres of mercury, yet the oxygen remained liquid. Liquefied nitrogen, when allowed to evaporate under a pressure of sixty millimetres of mercury, gave a temperature of −214° C., only the surface of the liquid gas became opaque from incipient solidification. Under lower pressures the nitrogen solidified, and temperatures as low as −225° C. were recorded by the hydrogen thermometer. The lowest temperature obtained by allowing liquefied carbonic oxide to vapourise was −220·5° C.

INTEMPERANCE AND PAUPERISM.

SEVERAL different causes have been assigned for the pauperism which is increasingly prevalent in our great cities. It is well that everything which has an influence on this subject should receive due attention at the present time, when the greatness of the evil is rendered more apparent by a general depression in trade, and when the minds of all are turned to consider any possible schemes for the proper maintenance and housing of the poor. The destitute man, if he were now asked to state the cause of his condition, would almost certainly blame the times, and would be largely justified in so doing. Whatever be the origin of the present inaction, whether business competition, the store system, the spendthrift extravagance of many whom a false ambition tempts to live above their means, or other circumstance, the fact remains that work is more difficult to find and to hold than formerly. Nor does the very poor man alone suffer, but the shoe pinches everyone in some degree. This want of employment and lapse of the regular habits which belong to it, have doubtless very much to do with such poverty as is generally felt. It does not, however, account for all the misery of the so-called "outcast" population. Other factors enter into that dismal pressure which rests upon each member of many households, not alone in our days, but even in more prosperous times. It was not for the first time at a recent meeting in Exeter Hall that drunkenness and unthrift were condemned as the twin and chief producers of abject poverty. The connexion between those vices is too much a matter of daily remark to call for proof. It is as real as the opposite

union between thought and thrift. Words are not needed to explain how the poor must go to the wall when trade is slack, if their exchequer, never too full, is in literal liquidation on behalf of a morbid appetite, while the giving hand of the employer is restrained by an enforced economy. On our own part, also, as medical men, we cannot but speak in support of these opinions of the political moralist. Science recommends alcohol to no one who has health; but, on the contrary, enjoins abstinence in this particular to all such, and in reference to all states of labour, mental or bodily, to exposure, worry, and even fatigue. In circumstances of exposure and exhaustion, indeed, testimony goes to prove that such drinks as tea and coffee afford a stay nearly as speedy in action as, and much more trustworthy and enduring than, any that alcoholic stimulants can give.

A NEW TEST FOR BILE ACIDS IN THE URINE.

DR. OLIVER of Harrogate has, during the past week, been demonstrating in several of the London hospitals what he believes to be a new test for the detection in the urine of the derivatives of the bile salts. It is in the form of a test solution, and also in that of test paper. The reaction of the test is founded on the physiological fact that where the bile mingles with the acid solution of peptones in the duodenum, the proteids are instantly and completely precipitated. The test solution is an acidulous antiseptic solution of peptone, and does not present to the urine a constituent extraneous to the organism. When brought into contact with a urine containing a bile-salt derivative, a precipitate resembling that of albumen when thrown down by nitric acid at once appears. By using a standard of opacity to represent the very delicate reaction induced in normal urine, Dr. Oliver showed how the quantity of the bile derivatives, as they appear in the marked deviations encountered in disease, can be readily gauged. He has, we learn, found bile acids plentifully present not only in the urine of jaundice and of other hepatic affections, but in that of several cases of anæmia (simple or idiopathic, leucocythæmic or malarial), and of other morbid conditions; and his observations generally appear to be of some clinical interest. We understand that Dr. Oliver is preparing for early publication the data he has collected.

PROPOSAL FOR A HOSPITAL FOR INFECTIOUS DISEASES IN BARCELONA.

THE Royal Academy of Medicine and Surgery of Barcelona is trying to persuade the municipal authorities to construct a hospital for infectious diseases, the want of which has been very much felt; and with this object in view publishes some suggestions on the subject, of which the following are the most important. The Academy decidedly objects to the plan of building a single hospital to contain a hundred beds, which is the number the new establishment would accommodate, but prefers a number of small pavilions, each devoted to a different form of infectious disease. The City Hospital should, according to the views of the Academy, contain six pavilions—two for "typhus" (for males and females), one each for small-pox, measles, scarlatina, and diphtheria, a movable partition being employed when necessary to separate the sexes. The Academy intentionally refrains from recommending a convalescent pavilion or quarter, because of the risks which would thus be incurred of, for example, a typhoid convalescent contracting scarlatina from some desquamating convalescent. The hospital should be situated far from the city, so that the focus of contagion might be sufficiently removed to be harmless to the inhabitants, and also prevent the possibility of its being stigmatised as the cause of any cases of infectious disease which might occur in its vicinity. The site should be an elevated one, so as to be above the miasms and mists of the low-lying ground, and also to favour the removal of its own sewage, which should be previously disinfected. It should lie to the north of the city, so that it could enjoy as much freedom as possible from the effluvia which the prevailing winds carry with them, and be at some distance from the sea, so as to be beyond the influence of the deleterious emanations from the port and the adjoining marshes. No plantations of trees, except of certain kinds—as, for example, the eucalyptus—should be permitted within the grounds of the establishment. The laying out of the site should be undertaken with special reference to the facility of drainage, and the surface should be covered with cement or other impermeable material.

THE MACLEAN MEMORIAL FUND.

WE observe that Dr. McLeod, secretary to the above Fund, has addressed a circular to Indian medical officers on furlough inviting subscriptions, no one of which is to exceed a guinea. Our readers are aware that it is proposed that the memorial should take the form of a portrait of Professor Maclean, to be hung on the walls of the Netley Hospital, and that, if funds permit, a replica of the portrait will be presented to Mrs. Maclean. Subscriptions should be forwarded, with the least possible delay, to Messrs. Grindlay and Co., 55, Parliament-street, Westminster.

NO MEDICAL OFFICER OF HEALTH.

A NUISANCE connected with a show of fat women, giants, and Zulus having been the subject of much complaint in Woolwich, the Local Board commissioned Mr. Lett, the parochial medical officer (Woolwich not possessing a medical officer of health), to visit and report upon the condition of the premises. He certified them to be in a most dirty state. A discussion arose as to why Mr. Lett had been appointed in preference to other practitioners, and it was stated that it was the usual custom to ask the union medical officer to report upon such cases in his own district. The fee for such report was half a guinea. The case shows the unsatisfactory way in which sanitation is conducted without a medical officer of health. If there had been such an officer, he would probably have taken action in this case some weeks before the board saw fit to issue a special request to the parochial medical officer, whose responsibility, besides, ends as soon as he has made his report.

THE VACCINATION LAWS.

MR. HANNAY, of Worship-street Police-court, has granted a warrant to levy on the goods of a person in Hackney for non-compliance with the Vaccination Acts, with the approval of the Home Secretary. It is unsatisfactory to find Mr. Picton plying the President of the Local Government Board with irrelevant questions on the Vaccination Laws. It is some set off to see that they did not make much impression on this member of the Government, who said there is no falling off in the proportion of vaccinated children to those born, and no intention to propose any further inquiry into the working of the Acts.

DR. ANGUS MACKINTOSH has issued, in the form of a card, a "Memorandum of Infectious Diseases," which presents in a concise form the leading facts known as to the latent period, the time of the appearance and cessation of eruption, and the date at which the patient ceases to be infective after the fever, in small-pox, typhoid, typhus, and scarlet fevers; diphtheria, measles, and whooping-cough. The card is likely to serve a useful purpose, and appears to be drawn up on the best-established data.

FROM the report of the examination made by Colonel Sir Francis Bolton, C.E., of the water supplied by the several metropolitan water companies during the month of January, it appears that the Thames water sent out by the Chelsea, West Middlesex, Southwark, Grand Junction, and Lambeth Companies contained on the whole the same proportion of organic matter as the previous month's samples, the amount being, except in the case of the Southwark and Grand Junction Companies, decidedly below the average for the time of year. Of the water drawn from the Lea, the New River Company's supply contained very much less organic matter than any of the other river waters, whilst the East London Company's water resembled in this respect the average of the samples derived from the Thames. All the samples were clear and bright.

THE Hon. Joseph Docker, M.R.C.S. Eng. (1824), L.S.A. Lond. (1852), M.L.C., died at his residence in Sydney on December 11th, in his eighty-third year. Mr. Docker, some time after settling in New South Wales, became a member of the Legislative Council, and in 1866 Postmaster-General. In 1868 he was appointed to the office of Colonial Secretary, and in 1870 again became Postmaster-General, remaining in office until 1872. In 1875 he was Minister of Justice and Public Instruction, and latterly he filled the office of Chairman of Committees in the Upper House.

AT Sydney, on December 10th, Dr. Donovan, charged by the Board of Health under the Infectious Diseases Suppression Act with failing to report a case of eruptive fever reasonably supposed to be small-pox, was fined £50, the highest penalty, or in default three months' imprisonment. On the 16th of December Dr. Donovan was again prosecuted for neglecting to report three other cases of small-pox which had come under his treatment, and, pleading guilty, was in each instance mulcted in the same penalty as on the previous occasion.

THE Canal Boats Act of last year is being carried out with vigour by the Local Government Board, an inspector having already visited many of the lines of canal traffic and reported on the action of the local sanitary authorities in regard to what the law requires. It is, however, stated that local bodies have to a great extent failed to enforce the provisions of the Act, and a circular letter is about to be addressed to them urging them to bestir themselves.

RUMOURS deemed false having been circulated as to the cause of the death of the great painter M. Bastien Lepage, Dr. Watelet, his medical attendant, wrote to the *Matin* stating what, in his opinion, was the true cause. The *Temps* has recently announced that a prosecution *ex officio* of Dr. Watelet is being undertaken for violation of professional secrecy, and against the *Matin* as his accomplice in the misdemeanour.

PLAGUE is stated to have broken out at Ojagh, sixty miles from Hamadan. Ninety deaths have been already recorded. Measures have been taken to prevent the spread of the disease.

MESSRS. LONGMAN will very shortly issue a new edition, edited by Dr. Lauder Brunton, of Murchison's "Clinical Lectures on Diseases of the Liver, Jaundice, and Abdominal Dropsy."

AT a meeting of the Medical Society of Bordeaux, M. Durodié exhibited a case of sweating limited to the right side of the body in a man aged fifty.

THE first annual report of the Medical Women for India Fund has been issued. The receipts have amounted to 41,842 rupees, and the disbursements to 13,799 rupees. Twelve female students have completed their first year of study at the Grant Medical College in a satisfactory manner.

A MEMORIAL in favour of Dr. Bradley, signed by ninety-six members of the medical profession of Sheffield and its vicinity, has just been forwarded to the Home Office.

THE fourth meeting of the German Medical Congress will be held at Wiesbaden on April 8th and three following days, under the presidency of Professor Frerichs.

MR. G. BAINBRIDGE has been appointed to act as Professor of Surgery in the Grant Medical College, Bombay, vice Mr. W. Gray, on furlough.

ZIEMSSEN'S Cyclopædia is being translated into Spanish by Dr. Francisco Vallina, and is being published in Madrid in monthly parts.

DR. COOK has been elected Dean of the Medical Faculty of the Bombay University, vice Mr. Hojel.

Pharmacology and Therapeutics.

"CONSTANT" TINCTURES.

IT is a fact which has long been familiar to every practical therapeutist that all the pharmacopœial tinctures may vary enormously in strength and in the proportion of active ingredients they contain. A patient, let us say, is taking tincture of belladonna; the dose is gradually and cautiously increased, and no ill effects result. In consequence of a change of residence or from some other accidental cause the prescription is dispensed by another chemist, and suddenly, and without any apparent reason, the full physiological action of the drug is produced, the physician is discredited, and the life of the patient is placed in imminent danger. This is no fancy sketch, for we have known this occur quite recently in London under circumstances almost identical with those we have indicated. The fact is—and it cannot be too generally known—that such terms as "tincture of belladonna," "tincture of opium," "tincture of nux vomica," and so on, have no definite meaning. For example, one specimen of tincture of nux vomica may contain just twice as much strychnia as another. There is a growing tendency, especially in hospital practice, to obtain drugs at the lowest possible rates, and in many cases the price paid is so low that it would be impossible for any druggist to supply a really trustworthy article for the money. It of course looks well in an annual report to be able to state that the expenditure on drugs is much less than it was in the previous year, and that the cost per head is less than at any other hospital; but these results are too often obtained at the expense of the sick and suffering, who at all events have a right to expect that they will have the best medicines obtainable. We are glad to see that a firm of chemists so well known as Messrs. Squire and Sons of Oxford-street have determined to do their best to oppose this pernicious system. They keep only one quality of tinctures, and these are standardised. Their method of procedure is as follows:—They obtain a typical specimen of the pure crude drug, which is then "hand-picked"; that is to say, all doubtful and damaged seeds or leaves, or whatever it may be, are rejected and thrown away. A tincture is then prepared according to the pharmacopœial process, and the amount of alkaloid—or of combined alkaloids, should there be more than one—is ascertained by actual analysis. This is repeated several times, and the mean of these results is taken as the standard. Every batch of tincture subsequently prepared is analysed in the same way, and, by the careful addition of crude drug or of spirit, as the case may be, is made to conform to this standard. Tinctures so prepared are called "constant tinctures," a

term which undoubtedly expresses in a convenient form their chief characteristic. The advantage of having a tincture which is always of one strength is incalculable, and Messrs. Squire and Sons undoubtedly deserve the best thanks, both of doctors and patients, for the enormous labour they have undertaken in connexion with this subject. We have given these tinctures a prolonged trial, extending over some months, and can speak of them in the highest possible terms. They are very little dearer than the common tinctures (only a few pence in the pound), and we trust that the day is not far distant when they will be in use in every hospital throughout the country.

SWEET SPIRITS OF NITRE.

The composition of sweet spirits of nitre and kindred preparations is a subject which seems destined to disturb the equanimity of dispensers and pharmaceutical chemists. It is stated that the Council of the Pharmaceutical Society have recently thought it necessary to convey their views on the matter to the authorities of the Inland Revenue at Somerset House. The exact nature of their communication is not known, but it is understood that the Council maintain that there is no positive evidence that the medicinal value of sweet spirits of nitre depends on the presence of nitrous ether, and that any specimen which is of proper specific gravity, and gives indications of containing *some* nitrous ether, may be regarded as having been prepared according to the directions of the British Pharmacopœia. With respect to the sweet spirits of nitre of the old London Pharmacopœia, they are of opinion that the proportion of nitrous ether which it contains often amounts to little more than a trace, and that the only tests necessary to show that such an article may be considered to be of good quality are those of odour, flavour, and specific gravity. They further state that the tests laid down in the British Pharmacopœia, and other tests devised with a similar object, cannot be supposed to be applicable to preparations sold for domestic use. A common argument used by druggists is, that an article supplied by a large manufacturer chiefly to medical men has a density of ·887, and that although it contains little or no ethyl nitrite, few complaints are made. These views, we must admit, have taken us somewhat by surprise. It would seem that the authorities of the Pharmaceutical Society are of opinion that the absence of the chief constituent from a preparation is a matter of very little importance if only the omission is not detected. This is a code of morality to which we are unaccustomed, and we are decidedly of opinion that no pharmacist or body of pharmacists has any right to change the character of a well-known preparation, or to supply an article essentially different from that which the medical man supposes his patients are taking. It is a subject of considerable importance, and one by no means which should be overlooked.

HYDROCOTYLE ASIATICA.

There can be no doubt that there are in common use in India many drugs the properties of which might be investigated with advantage with the view to their introduction into practice in this country. We understand Messrs. T. Christy have just received a large consignment of Hydrocotyle asiatica, a plant which in the East bears a high reputation in the treatment of leprosy, syphilitic and skin affections, ozæna, and a number of other diseases. At present very little is known with certainty about it; but we understand that it belongs to the natural order umbelliferæ, and that it has many native names, the most common of which are "Bráhmamanduki," "khulakhudi," and "thalkuri." It grows freely in the neighbourhood of Bombay, although it is more frequently found in gardens than running wild. It flowers abundantly if watered, sending out long runners like the strawberry, and producing leaves and root and fruit at the joints. The fresh herb has an aromatic ivy-like odour, and when crushed a nauseous bitter taste; but these qualities are to a great extent lost on drying. Its properties have recently been investigated by Mr. A. Jayesingha, sub-assistant colonial surgeon of the Government Dispensary, Ballapitimodera, Ceylon, and we have been favoured with a statement of his results. The drug was administered in the form of powder in ten-grain doses three times a day. It was also used locally as a poultice to ulcers, as a snuff in ozæna, and as an ointment mixed with lard in various skin diseases. The list of cases treated includes two of parangi, five of ozæna, two of leprosy, three of itch, two of secondary syphilis, one of herpes zoster, seven of parangial ulcer, and three of common ulcer. In twenty-one of these cases a cure was effected, or at all events the patient obtained marked relief. The failures are attributed to the irregular way in which many of the patients attended at the dispensary.

ARMY AND INDIAN MEDICAL SERVICES.

IN the papers on the subject of the Indian Army reorganisation, printed by order of the House of Commons, there is an interesting document on the Medical Service in India. The Reorganisation Commission pointed out the importance of abolishing the costly system of maintaining a double staff, and submitted their views of the mode in which this change should be effected. The Government of India were fully impressed with the necessity for a radical reform of the Medical Service, and were satisfied "that the needful improvement, both economical and administrative, is to be found only in some measure of unification." They were not, however, satisfied with the scheme proposed by the Commission, and invited the two heads of the Medical Service in India, Dr. Crawford, Surgeon-General to Her Majesty's Forces (now Director-General of the Army Medical Department), and Dr. Cuningham, Surgeon-General with the Government of India, to prepare a memorandum on the subject based upon two conditions which were deemed essential: "First, that there should be only one medical service for India; and, secondly, that complete authority over the medical service serving in India, as to employment, distribution, and remuneration, shall rest with the Government of India." A joint memorandum, prepared by these two officers, and dated Simla, 12th August, 1881, was submitted to the Government, and considered by them "to satisfy all the essential conditions of the case and to provide a satisfactory solution of the difficulty." It is a document of some length and bears evidence of careful consideration, having regard to efficient and economical administration and to respect for the rights and privileges of the existing officers. The memorandum recommends that there should be but one medical department, to be styled the Royal Medical Service, and to be divided into two branches, one for general and the other for Indian service, but that in any national emergency the Indian branch should be available, with the sanction of the Indian Government, for service in any part of Her Majesty's dominions; and the general branch, with the sanction of the Home Government, for service in India. It proposed that the Indian branch should be recruited by volunteers from the general list of officers under three years' service, that they should form one service for all India, primarily military, but also civil; the first two years to be spent in strictly military duty; after that period officers to be eligible for civil employ if they have passed the language test, but liable at all times to be recalled for military service if wanted. After ten years' continuous civil service, if they do not return to military duty, they must look for promotion to the administrative grade in the civil branch only. It is recommended that exchanges should be freely allowed between the general and Indian branches, but no Brigade Surgeon of the Indian branch to be eligible for promotion to Deputy Surgeon-General of that branch unless he has had five years Indian service above the rank of surgeon, and no Deputy Surgeon-General to be allowed to exchange into the Indian branch who has not had this qualifying service. Transfers also should be permitted from one branch to the other, when required in the interests of the service, and subject to the concurrent approval of both Secretaries of State. The memorandum proposes one administrative head, with the Government of India, for the whole Indian Medical Service, with a special rate of pay, who should recommend for all departmental promotions, and distribute officers to the several sections requiring them, civil, military, and sanitary; transferring medical officers from military to civil service and *vice versâ*, as may be necessary, but not interfering with the employment of any officer after being so posted, which would rest with the administrative medical

officer immediately concerned. The Indian Director-General "would communicate with the Director-General of the Royal Medical Service in all matters regarding recruiting, exchanges, and transfers, and would report all casualties by death, retirement, &c.; he would also, as Sanitary Commissioner, prepare, as at present, an annual sanitary report for the whole of India." Under the Director-General there would be a Surgeon-General for the army, on the staff of the Commander-in-Chief, charged with the medical administration, and having the control of the medical staff of the forces, and provided with the necessary administrative staff. The civil medical administration would continue much as at present, but without the local rank of Surgeon-General, the chief in each local government and administration being designated simply as "Principal Medical Officer." Such are the most important of the recommendations for the reorganisation of the Royal Medical Service. For the subordinate civil service, it is proposed to constitute an "Indian Medical Service," consisting of two classes—Assistant Surgeons and Civil Medical Officers, recruited from natives of India who are licentiates or graduates of medicine of an Indian college, the admission to be by competitive examination and the promotion by seniority on passing an examination test, but with power to promote specially assistant-surgeons who have distinguished themselves, or for the Governor-General to appoint direct to the higher grade should he think fit. The officers of this branch of the service to be liable to be called upon, on emergency, to perform work in military hospitals within their own province, or with troops of their own province serving elsewhere.

The reporters have fully considered and reported the mode in which this proposed system may be carried out with greatest advantage to the service and without inflicting any injustice upon the officers now serving, but it does not appear necessary here to enter upon such details. They also have discussed the question of pay and allowances, and recommended the abolition of the distinction of *unemployed* pay—a recommendation which has been already acted upon. We are glad to find also that they call attention to the injustice so frequently inflicted on officers who are required to pay their own expenses on being removed to a new charge. "An officer so moved from a doing-duty, or a so-called 'unemployed,' position to an officiating medical charge, which may not bring him more than one hundred rupees a month, but who, in consequence of the increased rate of pay he will draw, is obliged to join at his own expense, is frequently involved in expenses which months of such allowances will not cover." We trust that this regulation, against which we have so frequently protested, will soon be abolished, and one of the causes of justifiable discontent on the part of the Indian medical officers be thus removed. They also recommend a revision of the regulations by which charge pay is drawn by officers going on furlough or accepting civil appointments, while the officer who actually discharges the duty receives only a modified allowance; the rule adopted in the Army Medical Staff should be followed, that charge money be drawn by the officer on whom the duty and responsibility devolve.

A letter from the Under Secretary of State for War reviews these recommendations, and states that Mr. Childers, who was then Secretary of State, did not concur in the views of the reporters. The principal grounds of dissent were that he thought the proposed change would have the effect of diminishing the supply of candidates, as "the attraction of Indian service as an inducement held before the whole body of candidates would be seriously diminished;" that the least eligible of the candidates would be left for the British branch of the service; that both India and Great Britain would be losers in the matter of varied experience on the part of medical officers; and that the proposed scheme would be more expensive to India than a simple unification. Mr. Childers approved, however, of the proposal for the amalgamation of the two services, and suggested that, as the number of appointments to be supplied by the Army Medical Department would be increased, the term of five years for service in India should be raised to seven, and that an officer selected for a civil appointment should be allowed to volunteer for another term of seven years.

We have endeavoured to summarise as briefly as possible the recommendations contained in the memorandum. It gives the carefully considered opinions of two officers of long and varied service, representing the two branches of the existing Medical Service. The dual service in India has already been considerably modified, and it appears desirable, in the interests alike of the public and of the officers of the Medical Service, that still further improvements should be introduced. The form which these should take is clearly laid down in the memorandum now published, as well as the objections to it from a War Office point of view. It is obvious that the present system of two distinct and independent services working together in India is open to very serious objection, and that measures must be adopted to remedy the inconvenience and reduce the expense arising from such an arrangement. The principles laid down by Dr. Crawford and Dr. Cuningham appear well calculated to effect these objects, and at the same time to preserve intact the rights of the officers in accordance with the conditions of the warrants under which they joined the service. Whatever form of departmental organisation may be adopted, we trust the Government will give due effect to the recommendations bearing upon the existing system of charge pay and of travelling expenses.

POOR-LAW MEDICAL OFFICERS AND THE MEDICAL REGISTER.

AT a meeting of Council of the Poor-law Medical Officers' Association, held at their rooms, 3, Bolt-court, Fleet-street, on March 3rd, attention was drawn to the case of Mr. H. C. Linden, district medical officer of the Bingham Union, Notts. This gentleman had applied for and obtained a Poor-law medical appointment, his election to which was annulled by the Local Government Board on account of his name not appearing on the Medical Register through his not apprising the Registrar of his change of residence. Proof having subsequently been given to the board of guardians that his name had been restored to the Register, he was re-elected; but on his applying for his quarter's salary he was told by the clerk that the Local Government Board had declined to sanction the payment. The Council desires to express its opinion that a great injustice has been done to Mr. Linden, and that he is entitled to the sympathy and support of the profession, and it also wishes to impress upon Poor-law medical officers the importance of immediately informing the Registrar of any change of residence.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Alnwick and Canongate Urban District.—The mortality during 1884 was at the rate of 20·3 per 1000. The need for some means of isolation has often been referred to, and during the cholera prevalence of last year there was some hope that it would at last be provided. But the disease did not reach beyond the coast line and the matter appears again to be set aside. Hence Dr. Davidson once more presses it, and he shows that for scarlet fever alone it is much needed. Diarrhœa was somewhat exceptionally prevalent, and phthisis is also a leading disease of the place, the cause of the latter disease being attributed to the wetness of the subsoil and the breathing of vitiated air due to deficient ventilation and to overcrowding. Some parts of Alnwick are in a notoriously bad condition; one locality is described in the report as disgraceful, and in many of the yards surrounded by tenemented houses the same description would hold good. The soil is sodden with filth and water, and in summer foul emanations are the result. Old bye-laws are in force which fail to meet pressing sanitary needs as regards new buildings, and the committee appointed to deal with the matter does not appear to further the object required with the needed promptitude. As regards the common lodging-houses, the state of affairs which inspection has revealed is such that it cannot, we hope, be allowed to continue. Alnwick has just now an unenviable notoriety. The public have complained of its condition, a coroner's jury have blamed the authorities, and the Local Government Board have directed inspection of its sanitary state. Notwithstanding the changes in the post

of officer of health, Dr. Davidson does not fail faithfully to show the authority the direction in which its future work should lie; and we trust that both for the sake of the inhabitants whom they represent, and for their own sakes, the Town Council will during the present year set themselves earnestly to work.

Stroud Urban District.—The town has a death-rate of 17·2 per 1000, and a birth-rate of 21·3. The number of uncertified deaths amongst infants is high, and Mr. Partridge attributes it to an important extent to the practice which prevails amongst ignorant mothers of dosing their children with soothing syrups and other nostrums instead of securing that medical aid which is open to the poorest in the country. Some enteric fever and diphtheria have occurred in connexion with the use of polluted well water, and, as a result, some extension of the town mains has been made. Inspection of bakeries, slaughter-houses, &c., continues, and a good list of sanitary work is recorded.

Stroud Rural District.—In this rural district certain works of drainage are in progress; the water-supply is subject to frequent and careful inspection, all suspicious sources being examined and dealt with. Horsley is spoken of as being much in need of a proper supply in place of the present one, which is subject to the risk of pollution. Stonehouse, which has more than once been to the front as a place needing sanitary measures, is again referred to in connexion with the prevalence of enteric fever. The place is, however, now being drained.

Huntingdon Rural District.—In the Alconbury and Sawtry division of this district steady work is in progress as to the prevention of disease and nuisance. Alconbury brook has been cleansed in so far as the duty devolved on private owners, and so a large improvement has been effected; but further action in the same direction is required by the authority. Sawtry is also in urgent need of a good water-supply. The death-rate for the district was 13·3 per 1000 during 1884. There was one death from scarlatina and two from non-spasmodic croup.

St. George, Hanover-square.—During the year ending March 25th, 1884, this parish exhibited a lower death-rate than for years past—namely, one of 15·7 per 1000. Apart from diphtheria, infectious diseases caused but few deaths, and a majority of the diphtheria deaths occurred in St. George's Hospital. The report is in the main statistical; but the inspector of nuisances compiles a goodly table, showing the current sanitary work of the year; and Dr. Corfield shows also that a large amount of disinfection is carried out in the hot-air chamber with which the parish is provided. In view of the possibility of cholera appearing, arrangements were made for the isolation of the sick. Dr. Corfield communicated with the Duke of Westminster as to the site he regarded as the one most applicable, and the Duke gave his assent, and went so far as to issue notices to the then occupiers to quit. Fortunately, no use had to be made of the permission thus acquired.

Woodford Urban District.—Dr. Groves attributes some occurrences of diphtheria to emanations from sewer ventilators which open on the road level, and he quotes THE LANCET as endorsing his views on the subject. On this matter being brought before the authority they determined to make inquiry of the sanitary authority of Surbiton, where, according to Dr. Groves, a system of ventilating the sewers at a high level is in existence. The death-rate in Woodford was 14·2 per 1000 during 1884 and 12·1 in 1883, and so far as the medical officer of health can ascertain there was not last year even a single case of enteric fever.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5937 births and 3660 deaths were registered during the week ending the 28th ult. The births exceeded by 123 and the deaths by 33 the average weekly numbers during 1884. The annual death-rate in these towns, which had steadily declined in the preceding four weeks from 24·5 to 20·5 per 1000, rose again last week to 21·4. During the first eight weeks of the current quarter the death-rate in these towns averaged 22·8 per 1000, against 24·6, the mean rate in the corresponding periods of the nine years 1876-84. The lowest death-rates in these towns last week were 13·9 in Portsmouth, 14·3 in Huddersfield, 15·7 in Hull, and 16·9 in Halifax. The rates in the other towns ranged upwards to 29·6 in Sunderland, 30·3 in Newcastle-upon-Tyne, 31·7 in Cardiff, and 32·2 in Preston. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 398 and 384 in the previous two weeks, further declined last week to 377; they included 113 from whooping-cough, 102 from measles, 44 from scarlet fever, 32 from "fever" (principally enteric), 31 from diphtheria, 31 from diarrhœa, and 24 from small-pox. No death from any of these zymotic diseases was recorded last week either in Derby or in Halifax, whereas they caused the highest death-rates in Preston, Norwich, Cardiff, and Sunderland. The highest death-rates from whooping-cough occurred in Preston, Bristol, Wolverhampton, and Norwich; from measles in Cardiff and Sunderland; from scarlet fever in Preston; and from "fever" in Norwich. The 31 deaths from diphtheria in the twenty-eight towns included 16 in London, 3 in Nottingham, 3 in Liverpool, and 2 in Leeds. Small-pox caused 38 deaths in London and its outer ring of suburban districts, 2 in Birmingham, 2 in Sunderland, 1 in Brighton, and 1 in Liverpool. The number of small-pox patients in the metropolitan asylum hospitals situated in and around London, which had been 1223 and 1141 on the preceding two Saturdays, further declined to 1103 at the end of last week; the admissions, which had been 255 and 163 in the previous two weeks, were 170 last week. The Highgate Small-pox Hospital contained 98 patients on Saturday last, 19 cases having been admitted during the week. The deaths referred to diseases of the respiratory organs in London, which had steadily declined in the preceding four weeks, from 556 to 343, rose again last week to 384, but were 105 below the corrected weekly average. The causes of 79, or 2·2 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leeds, Bristol, Leicester, Portsmouth, and in six other smaller towns. The largest proportions of uncertified deaths were registered in Sheffield, Preston, and Newcastle-upon-Tyne.

HEALTH OF SCOTCH TOWNS.

The annual death-rate in the eight Scotch towns, which had steadily declined from 30·2 to 23·1 per 1000 in the preceding four weeks, rose again to 24·6 in the week ending the 28th of February, and exceeded by 3·2 the mean rate during the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 13·3 in Perth and 16·0 in Edinburgh, to 26·2 in Dundee, 29·0 in Glasgow, and 35·2 in Paisley. The 600 deaths in the eight towns included 31 which were referred to whooping-cough, 17 to scarlet fever, 15 to measles, 11 to diarrhœa, 6 to "fever" (typhus, enteric, or simple), 2 to diphtheria, and not one to small-pox; in all, 82 deaths resulted from these principal zymotic diseases, against 95 and 81 in the preceding two weeks. These 82 deaths were equal to an annual rate of 3·4 per 1000, which was 1·2 above the mean rate from the same diseases in the twenty-eight English towns. The 31 deaths from whooping-cough showed a slight further increase upon the numbers in the previous two weeks. The fatal cases of measles, which had been 25 and 21 in the previous two weeks, further declined to 15 last week, of which 12 occurred in Glasgow and 2 in Dundee. The 17 deaths from scarlet fever, however, showed a considerable increase upon the numbers in recent weeks, and included 14 in Glasgow and 2 in Paisley. Of the 11 deaths attributed to diarrhœa 5 occurred in Dundee. The 6 deaths referred to "fever" were considerably below the average. Both the fatal cases of diphtheria (a lower number than has been returned in any recent week) occurred in Glasgow. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had declined in the preceding four weeks from 214 to 139, further fell last week to 125, but exceeded the number returned in the corresponding week of last year by 17. The causes of 17, or nearly 12 per cent., of the deaths registered last week in the eight Scotch towns were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been equal to 36·2, 34·9, and 30·4 per 1000 in the preceding three weeks, further declined to 30·3 in the week ending the 28th ult. During the first eight weeks of the current quarter the death-rate in the city averaged no less than 32·7 per 1000, the mean rate during the same period not exceeding 21·9 in London

and 20·6 in Edinburgh. The 205 deaths in Dublin last week showed a further decline of 1 from the numbers in recent weeks, and included 18 which were referred to the principal zymotic diseases, against 20 in each of the previous two weeks. Of these 18 deaths, 8 resulted from measles, 6 from scarlet fever, 2 from whooping-cough, 1 from "fever" (typhus, enteric, or simple), 1 from diarrhœa, and not one either from small-pox or diphtheria. These 18 deaths were equal to an annual rate of 2·7 per 1000, the rate from the same diseases being equal to 1·8 in London and 1·9 in Edinburgh. The fatal cases of measles in Dublin, which had been 10 and 11 in the preceeding two weeks, declined to 8 last week; the deaths from scarlet fever, on the other hand, rose to 6 last week, from 3 in each of the previous two weeks. Only 2 deaths from "fever" have been recorded in the city in the past fortnight, whereas they averaged 4 per week in the first seven weeks of this year. Seven inquest cases and 2 deaths from violence were registered within the city; and 61, or nearly a third, of the deaths were recorded in public institutions. The 39 deaths of infants showed an increase upon the number in the previous week, while the deaths of elderly persons were fewer than in any previous week of this year. The causes of 34, or more than 16 per cent., of the deaths registered in the city last week were not certified.

CLASS MORTALITY IN DUBLIN.

The death-rate in Dublin last year was equal to 27·9 per 1000 of the estimated population in the middle of the year. This high rate of mortality, although showing a decline of 1·3 per 1000 from the mean rate in the preceding ten years, bears most unfavourable comparison with the rates prevailing in the capitals of the other portions of the United Kingdom. In London the rate last year did not exceed 20·3, and in Edinburgh it was only 20·0. In the Registrar-General's yearly summary for Dublin and other large Irish towns further statistics are published with a view to elucidate that interesting but difficult problem of class mortality. The recorded death-rates during 1884 in the families of eighteen different occupational subdivisions grouped in five social classes are given in this report. Class mortality, as distinct from occupational mortality, is a branch of vital statistics that has not yet secured its due share of attention, in great measure owing to the inherent difficulties which the subject presents. The figures published by the Registrar-General of Ireland bearing upon class mortality in Dublin, crude as they are at present, form a welcome addition to our slender knowledge on the subject. Some time since, when we noticed these class death-rates in Dublin, we pointed out that such rates of mortality were practically useless for comparative purposes unless due allowance was made for the wide differences of age distribution in the various social classes. In order to estimate the true import of a death-rate, it is absolutely necessary to know the age constitution of the population upon which it is calculated. We have been pleased to notice that the Registrar-General of Ireland now affords the means for correcting his class death-rates for differences in the age constitution of the population in the several classes. A table is published in the yearly summary, recently issued, giving the ages of the Dublin population in each social class, and in each group of occupations for which the deaths are given. This information affords the necessary assistance for calculating the disturbing influence of age distribution upon this recorded class mortality. By applying standard life table rates of mortality to the varying proportions of persons living at five groups of ages in the four social classes adopted by the Registrar-General of Ireland, we find that the normal death-rate ranged from 19·5 per 1000 in the Middle class, to 25·2 in the Professional and Independent class. Bearing in mind that this difference of 6·3 per 1000 is entirely due to difference of age distribution in the living population of each class, it is impossible to doubt that the recorded death-rate in these two classes is useless for comparative purposes, unless due correction be made for this disturbing influence. The explanation of this important effect of age distribution upon recorded class death-rates is patent. It will be found from the Registrar-General's table to which we refer that in the Professional and Independent class population 15·8 per cent. are persons aged upwards of sixty years, whereas in the Middle class only 4·8 per cent. are returned at the same group of ages. This remarkable difference in the age distribution of two classes, between which the barrier must be ill-defined and more or less artificial, points to difficulties of classification of the social class and occupation of living and deceased persons, to which we shall probably hereafter refer.

THE SERVICES.

THE EGYPTIAN EXPEDITION.

We learn from our Indian contemporaries that the following Indian medical officers proceed on active service with their respective regiments forming the Indian contingent for the Soudan:—Surgeon-Major G. Hutcheson, M.D., 9th Bengal Cavalry, to which is attached for duty Surgeon G. Jameson; Surgeon-Major Kelly, M.D., 15th Sikhs; Surgeon-Major R. T. Lyons, M.D., 17th Bengal Infantry; Surgeon F. Burness, M.B., 28th Bombay Infantry; and Surgeon-Major R. V. Power, M.D., 12th Madras Infantry.

At Aldershot a further draft of the Medical Staff Corps, the officers and men for which have been drawn together from various outlying stations, is being prepared, and will probably embark at the end of the week for Suakim.

The Indian troopship *Crocodile* left Portsmouth on the 4th inst. for Bombay, having embarked, amongst other officers, on the previous day, Surgeon-Major Macpherson and Surgeons Dodd and Hunston, medical staff.

The Greenwich Hospital pension of £50 per annum, vacant by the death of Deputy Inspector-General of Hospitals and Fleets Alexander Crawford Macleory, has been awarded by the Lords Commissioners of the Admiralty to Deputy Inspector-General of Hospitals and Fleets William Hoggan.

WAR OFFICE.—Army Medical Staff:—The following officers are granted the local and temporary rank of Deputy Surgeon-General whilst serving with the Expeditionary Force, Suakim: Brigade Surgeon George Langford Hinde; Brigade Surgeon Samuel Black Roe, M.B., C.B. Surgeon-Major John Candy, M.D., has retired upon temporary half-pay.

ADMIRALTY.—Staff Surgeon Richard William Coppinger, M.D., has been promoted to the rank of Fleet Surgeon in Her Majesty's Fleet.

RIFLE VOLUNTEERS.—3rd Lancashire: Andrew Alexander Watson, Gent., to be Acting Surgeon.—2nd Battalion, the Queen's Own (Royal West Kent Regiment): Henry William Roberts, Gent., to be Acting Surgeon.

Correspondence.

"Audi alteram partem."

SLOW PULSE, WITH EPILEPTIFORM SEIZURES.

To the Editor of THE LANCET.

SIR,—The interesting case narrated by Dr. Gibbings in your issue of Feb. 14th reminds me of one, the notes of which I have long had by me with the object of publishing whenever a suitable occasion should present itself. I was much interested in it because it seemed to me to show conclusively the effect of cerebral anæmia in the causation of epileptic or epileptiform attacks.

The following is a copy, with only a few verbal alterations, of the case as I wrote it out at the time.

W. P——, aged thirty-one, was admitted under the care of the late Dr. Goolden on May 4th, 1869. He had been a soldier, and was in India for four years, during which time he contracted syphilis and suffered from "fever and ague." Was discharged after twelve years' service on account of "weakness of constitution." He has never had rheumatism, and never suffered from shortness of breath or palpitation previously to his present illness. This came on two weeks before admission. At that time, under some mental excitement, he jumped over some palings in order to prevent a fight. He was immediately attacked with faintness, but recovered from it very shortly. The next morning in bed he woke up with "heavy" breathing, which also soon subsided. In the evening it returned, and he had a fit in which he lost consciousness. From that time he has had to give up work, and attacks of dyspnœa, followed by losses of consciousness, have recurred frequently night and day up

to the time of admission. The fits have all been preceded by "faintness at the chest," followed by flushings, on the occurrence of which insensibility has supervened. He once bit his tongue slightly. Has had no pain in the chest or elsewhere. He was ordered to take quinine and iron and two glasses of wine.—14th: I saw him to-day for the first time, and learnt that almost constantly since admission his pulse had been beating very slowly, sometimes not more than 26 in the minute, and that he had had frequent fits night and day. These had been of very short duration and attended with a little struggling. He had been carefully watched by several of the advanced students in some of these fits, and according to them it seemed clear that the fits always came on at the end of an unusually long interval between successive cardiac beats; that while the pulse was at the rate of one beat in three seconds, or even four seconds, no fit occurred; but that whenever, and only when, the intermission was prolonged to five seconds a fit followed at the end of that period. He is free from fits this morning, and his pulse is beating regularly at the rate of 26 in the minute. There is a loud roaring systolic murmur above and to the right of the apex, and prolonged thence to the base.—18th: No fit from the 14th to the 17th; but since the middle of yesterday, and especially during the night, the fits have been very frequent. They vary in length, but insensibility only lasts for a few seconds. He becomes very pale before each fit, then flushes, and while insensible his hands twitch a little. When I saw him the fits had ceased, but the pulse was very irregular. A few regular beats at the rate of 80 in the minute were followed by one or two beats occurring at intervals of about three seconds. Systolic murmur loudest towards the base. A little later his pulse was quite regular at 80 per minute. —21st: Has had frequent fits night and day since the 18th, and has had several this morning. At the time of my visit the pulse is somewhat more irregular than it has been. There is an interval sometimes of three seconds, sometimes of four, without a beat, and then follows a succession of beats at the rate of 80 per minute. On listening to the heart, its sounds correspond accurately to the pulsations at the wrist; but between all the beats (attended with sound and perceptible at the wrist) separated from one another by intervals of between two and four seconds, there are one, two, or three slight impulses of the heart distinctly to be felt, and seen by the imparted movements of the stethoscope. These latter beats are wholly unattended by cardiac sound or pulsation in the arteries. It seems to me that the action of the heart is quite regular as to rhythm, but that many of its beats are ineffectual. These intermediate impulses are felt at the base of the heart; are they due to the action of the auricle or to the hardening of a relaxed but empty ventricle?—25th: Has been pretty free from fits, but had a slight one last night; slept well; feels better. Pulse about 80, but irregular. Rough murmur, loudest and roughest towards the base.—28th: No fits, but occasional sensation as if they were coming on. Pulse 58, regular.—June 1st: No fits; pulse 72, occasionally a little irregular; murmur as before; complains of pain in left shoulder, running down inner side of the upper arm.—4th: No fits; pulse 72, quite regular; feels much better.—8th: No fits, but pulse irregular; murmur as before; feels well. On this day he left the hospital, but he attended as an out-patient until the 21st. During this time, though his pulse continued to be somewhat irregular, he remained free from shortness of breath, palpitation, and fits, and expressed himself as feeling fairly well. I never heard of him subsequently. What my views of the morbid anatomy of the case were formerly I have not recorded, and do not recollect. I am inclined now to suspect that the cardiac disease was syphilitic.

It may be interesting in relation to the above case to record another in which similar epileptiform fits were the consequence of the opposite condition of temporary cerebral congestion. About ten years ago I was consulted by a gentleman sixty years of age, who was very fat and had been liable to bronchitis for many years. For several weeks or longer he had been suffering from severe prolonged paroxysmal attacks of cough with whooping inspiration, in the course of which he frequently became insensible and slightly convulsed for a few seconds. In my consulting-room one of these paroxysms of cough came on. It was much like an attack of whooping-cough, and after it had lasted for some time (half a minute or a minute) respiration suddenly ceased, he became increasingly livid in the face, his head fell upon his chest, and he was insensible and slightly convulsed for a few seconds. He then came to, and appeared in his usual condition. Whether he was really suffering from whooping-cough or not I do not know. I could not determine that point at the time, but I know that these phenomena continued unchanged for some considerable time after his visit to me, and that even during the next five or six years he still occasionally whooped, and still occasionally lost consciousness during severe attacks. I saw him again six years later, when he was suffering from the effects of advanced bronchitis, and about a month before his death from that disease. Attacks like the above are not uncommon, and occasionally cause death in children suffering from whooping-cough, but so far as I know they are rare in adults. Your obedient servant,

Old Burlington-street, Feb. 16th, 1885. J. S. BRISTOWE.

"WHAT WAS THE CAUSE OF DEATH?"

To the Editor of THE LANCET.

SIR,—As you have alluded to the case of the Norwegian sailor, Johnson, under the above heading in your issue of Feb. 21st, I hope you will allow me to explain briefly the facts. They are as follows:—

About 1 A.M. on the morning of Jan. 2nd the man, Johnson, was brought to the hospital, and found to be dead. On the 3rd, by the coroner's order, a post-mortem examination was made by me, at which there were present Dr. Little, honorary surgeon, and Mr. Gordon and Mr. Dixon, the two other house-surgeons. The examination occupied three hours, and every organ and every cavity was carefully examined. All those who were present were quite agreed as to the condition of the organs described below. What we found amounted briefly to this: Externally, several cuts and bruises about the head and face; internally, congestion of all the organs, considerable atheroma of the aorta, and nothing else. On Monday, the 5th, about 10 P.M., Dr. Whitford, called and said he had been engaged by the defence, and would like to see the body. Accordingly an appointment was made for eleven o'clock the next morning, the 6th. Dr. Whitford was not punctual, and before he arrived I had left for the coroner's court. However, he was shown the body by one of the other house-surgeons, and he made a hasty examination of the organs and the external injuries, the whole process occupying not longer than twenty minutes. The coroner's inquest was held the same day. The evidence of the witnesses was this: That one of the prisoners first engaged in an altercation with Johnson, and then the other two came to the assistance of the first; that Johnson was struck violently on the head several times with the buckle of a belt, and afterwards with a ginger-beer bottle, and that he died in a few minutes after receiving these injuries. After hearing this evidence I gave it as my opinion that the probable cause of death was concussion of the brain, and that the congestion of *all* the internal organs was due to his mode of death. Dr. Whitford then got into the box, and, without any previous communication with me, stated that he took a wholly different view of the matter; "that there was extensive and long-standing disease of the heart"; "that the left lung was *nearly entirely semi-solid*." When asked by the coroner to state the cause of death, Dr. Whitford replied, "I should find that difficult after all the examinations I have made, for none of the wounds I have found left sufficient traces of being enough to cause death. The deceased was much enfeebled by the condition of his lungs." The jury returned a verdict of "Wilful murder." In subsequent conversation with Dr. Whitford, I pointed out to him that the heart and the aorta were not quite the same, and I believe we agreed that the heart and its valves were healthy, but that there was considerable atheroma of the aorta. At the assizes Dr. Whitford described the left lung as "completely solid," and the right as "semi-solid." The jury without the least hesitation returned a verdict of "Manslaughter" against all the prisoners. On the next day Dr. Commins, addressing the Court in mitigation of sentence, was stating that the condition of the deceased man's lungs must have enfeebled him greatly, when he was interrupted by the Judge, who intimated that it was useless for counsel to pursue that argument, as the Court believed that the congestion of the organs was consequent on the assault.

To the questions asked in your article, I reply—1st. The congestion of the lungs was not greater than the congestion of the kidneys, and some of the other organs (which Dr.

Whitford omitted to mention), and was the same in kind and degree as that which is frequently found in persons who have died a violent death. 2nd. There was no consolidation in either lung. 3rd. The aortic degeneration was not more than might have been expected in a man of deceased's age and mode of life. 4th. This last question Dr. Whitford answered at the assizes. He was asked, "If deceased had not *received* these injuries how long would he have lived?" *He* replied, "He might have lived a week;" but as far as I can see there was no reason why he should not have lived for years. That the pathological changes found in the body had no apparent effect on the man's previous health may be assumed from the fact that he was considered by his wife to be a perfectly healthy man; and there can be no doubt whatever that he died from the effects of the brutal assault which was committed on him. For this assault there was no defence.—I am, Sir, yours faithfully,

F. KNIGHT, M.B. Lond.,
House-Surgeon, Royal Southern Hospital.

Liverpool, Feb. 25th, 1885.

MR. LEAKE AND THE ANTI-VACCINATIONISTS.

To the Editor of THE LANCET.

SIR,—I trust that you will permit me, in the public interest, as well as on professional grounds, to state what *I know* of the revaccination cases referred to by Mr. Leake. As the subject has now become public property, there cannot, I presume, be any reasonable objection to the exact circumstances being calmly narrated from the medical standpoint. On May 17th, 1881, eight members of Mr. Leake's household were revaccinated by me, six on the 18th, and four, including Mr. Leake himself, on the 22nd. All were then residing in a large roomy house in Hill-street, Berkeley-square, taken for the season; as to its sanitary state I have no information. Two of Mr. Leake's relatives residing in an adjoining street were "done" on the 18th, and their maid on the 22nd. To be exact, therefore, the operations numbered twenty-one, and, if I recollect rightly, at least one of the servants was, properly speaking, vaccinated. It was understood between Mr. Leake and myself that Brussels calf lymph was to be used, and I personally obtained the necessary supplies fresh as they were needed, in tubes, from Dr. Warlomont's agent in town. The operations were done by cross-scratching three places, at the usual distance apart from each other, over the deltoid, with the point of a clean Spratt's vaccinator; in one child, who did not look so strong as the rest, the lymph was applied in two places only. In short, every care and precaution was taken to ensure success.

On visiting the patients on May 23rd, 24th, 25th, and 26th, I found everything going on so well that I did not consider it necessary to call next day; but I left word that, if required, I was to be sent for at once. On the evening of the 27th my immediate attendance was requested. I found one of the servants, whom I had revaccinated on the 22nd, ill in bed. She had complained in the morning, but the housekeeper did not report the illness until shortly before my arrival. The quickened pulse, high temperature, sore-throat, and as yet faint blush on the front of the chest, could not, and did not, fail to arouse suspicion; but I declined to express a final opinion till next morning. As there was then no longer any doubt that we had scarlatina to deal with, not a minute was lost. The patient was quickly carried out of the house into the ambulance, which the London Fever Hospital sent at once in response to Mr. Leake's telegram. The bedclothes, &c., were bundled up and cast out of the top back bedroom window into the garden, and finally removed through the stable; sulphur was burnt for hours in the bedroom; and either carbolic acid or Condy's fluid was thrown down the waterclosets and sinks. Nothing was left undone to prevent the extension of the outbreak, and we were happily successful. Now began our anxieties as to the possible consequences that might follow the importation of scarlatina—how we knew not—into a household passing, hitherto normally, through the vaccinal process. Unfortunately, on June 1st, or thereabouts, one of the daughters, aged about sixteen years, fell ill, the arm became reddish and swollen, and gradually the vesicles broke down into deep ulcerated sores discharging unhealthy pus. She was taken home to near Manchester on the 7th, and her medical attendant there informed me in his letter of the 13th that a large abscess having a threatening aspect for a time formed in the axilla attended with erysipelas. There my information ends. I am under the impression that in another daughter the revaccination was a failure, owing to the vesicles running an irregular course, but after this lapse of time I am obliged to speak with some reserve. To the best of my knowledge and belief these two were the only patients out of twenty-one operated upon in whom the process, where it "took," did not pass through the normal phases. A third daughter accidentally made a very small puncture into the skin in front of the knee with the point of a pair of scissors. At that spot cutaneous erysipelas appeared, spreading downwards to the ends of the toes, and then upwards to the groin, where it stopped. This attack had no connexion whatever with the vaccinal puncture on the arm, which was unaffected. My last visit was on June 22nd.

If any of your readers have had a similar experience to the above, I hope they will make it known in your columns. My own opinion at the time, as stated to Mr. Leake, was that the untoward results just described could not, in fairness, be wholly, if at all, imputed to the lymph or the operation, but that the scarlatina had a good deal to answer for, and might have had more. The rule not to vaccinate in a house where scarlatina is known to prevail implies that scarlatina is hostile to vaccinia. There were no other cases of this disease at the time in the neighbourhood, to my knowledge.

As to the cost, my charges were ten guineas for twenty-one revaccinations, and four guineas for four visits—that is, fourteen guineas. The visits subsequently made to the scarlatina patient and to the children numbered thirty-seven, which at one guinea each brought my claim up to fifty-one guineas; but I do not see how the revaccinations can be debited with more than fourteen. In order to err on the side of moderation I made no extra charge when I had to attend a good many times on two or more patients at the same visit. Mr. Leake's error seems to me to consist in the fact that he lays all the blame on the revaccination, and no blame at all on the scarlatina.

I am, Sir, yours obediently,

Hertford-street, Mayfair, March, 1885. GEO. MOORE, M.D.

RECOVERY AFTER APPARENTLY FATAL CHLOROFORM NARCOSIS.

To the Editor of THE LANCET.

SIR,—Perhaps you may think the following instance of recovery from apparently complete death from chloroform worthy of insertion.

Some two years ago I was asked by a friend to remove a cataract from the eye of a favourite fox-terrier, the request being made with many apologies. I replied that I was as willing to give relief to the dog as to a human being, so the dog was brought. I found that it had necrosis of the central half of the cornea; so having chloroformed it, I made several incisions round the periphery of the necrosed portion. When I had finished, the dog was to all outward manifestation quite dead. My friend, Mr. W. O. Pughe, employed artificial respiration vigorously, but to no purpose. Suspending the animal by the heels had no better result. Artificial respiration was again tried, but still without avail. We next tried nitrite of amyl, but there was no response. All this had taken some time, and the case seemed hopeless, when it occurred to me to employ both artificial respiration and nitrite of amyl together. Two or three compulsory breathings of the amyl caused the dog to jump up and stagger about the room most actively. The eye recovered with scarcely an opalescence to mark the site of the necrosis. Since that time I have never knowingly given chloroform or had it given for me without having amyl nitrite at hand, although I am happy to say it has never been so imperatively necessary to use it as in the foregoing case.

I have seen only one case of chloroform death, and that occurred before the action of amyl nitrite was generally known; but I believe that had we treated the patient then as we treated the dog death would not have resulted. Now that ether has been used so much, is it not time to take stock to see whether it be so much safer than chloroform? My contention is that in the production of complete anæsthesia there is little or no difference between the two drugs, whilst in the after-effects, especially as regards vomiting, nausea, and depression of spirits, chloroform is much superior to ether.

I am, Sir, yours truly,

Liverpool, Feb. 22nd, 1885. GEORGE E. WALKER, F.R.C.S.

"INTEMPERATE ADVOCACY OF TEMPERANCE."

To the Editor of THE LANCET.

SIR,—I observe in your issue of the 21st of last month that you make some severe strictures on a speech I am supposed to have made somewhere and somewhen. You accuse me of making three assertions, which are in effect—(1) That medical men prescribe alcohol to increase their practices; (2) that under no possible circumstances ought it to be used; (3) that increasing death-rate is the gauge of our retrogression in drunkenness. I am surprised that you credit any member of the profession with making such absurd and silly statements without proper inquiry. I have before me a report of a speech in the *Weymouth, Portland, and Dorchester Telegram*, to which I suppose your remarks refer, and, though it is difficult for me to recognise my own speech, so imperfectly are the medical points stated, I defy anyone to find the slightest foundation for supposing I hold such opinions or have given expression to them. I did not go beyond what several medical men of great eminence have stated on the question. While holding most strongly the opinion that healthy persons do not need stimulants, I think in some cases it may prove valuable as a medicine, though it is not required even here so frequently as is generally supposed. I am, Sir, your obedient servant,

Southampton, March 2nd, 1885. JOHN H. ALDRIDGE.

*** Dr. Aldridge has misunderstood the extent of our reference to his lecture. We attributed to him only the third of the above assertions, and that on the authority of a report in a daily paper. His letter shows that in the main his theory of the use of alcohol is identical with our own.—ED. L.

MANCHESTER.

(*From our own Correspondent.*)

PROVIDENT DISPENSARIES.

AT the annual meeting of the provident dispensaries a report was presented which was considered by the committee to be of a very satisfactory character. Practically, they are now self-supporting; four out of the nine branches are making an annual profit on their work. The total subscriptions from members amounted to £3400, of which sum £1865 was paid to the medical staff, not including fees for confinements. One of the chief objects the Society has in view is to prevent abuse of medical charity whilst promoting the independence of the working classes in obtaining medical relief in time of sickness. Investigations are made into the means and position of applicants for relief at the various hospitals in the city, and the general result of this action has been to cause a large diminution in the number of those applying for gratuitous advice who are in a position to pay something for the same. Thus, at the Royal Infirmary the applicants found able to pay during the past year were 12 per cent., against 17 per cent. in 1878. Ten years ago more than 40 per cent. of the cases applying at our charities were found not to be fit objects of charity, whilst last year the percentage was only 14·9. This cannot but be regarded as a satisfactory result, if among this army of would-be medical paupers none truly deserving have been included. The charges at one time made by some members of the medical profession, that patients were allowed to become members of a dispensary who were really in a position to pay the ordinary fees of a medical man, have been of late but little heard, so that it may be assumed that this fairly legitimate complaint has been looked into and remedied.

MANCHESTER MEDICAL CHARITIES.

We have lately had rather an animated discussion going on in the daily papers in relation to the New Eye Hospital. It was at first intended on the completion of the new building to remove entirely the work of the hospital from the centre of the city, where it has hitherto been located, to the new hospital in Oxford-road, situated some mile and a half from the present site. This has led to a scheme being proposed for establishing another eye hospital near the old situation to provide for emergencies, and for the convenience of out-patients who live on the eastern side of the town and in Salford. As a result it seems that the present hospital authorities have decided to retain a portion of the old building in John-street to meet these requirements, and thus render a new institution unnecessary. It would certainly be a pity to still further multiply our now too numerous medical charities, most of them being constantly in difficulties to make their income balance their expenditure; the Lock, the Ear, the Children's, the Clinical Hospitals are all asking for increased subscriptions unless the work is to be curtailed. At the annual meeting of the last named, presided over by the Bishop of Manchester, it was advocated by some that wards for private patients should be tried as an experiment for those willing to pay; the experience gained, however, at the Children's Hospital, Pendlebury, does not give much encouragement to this proposal. At the first annual meeting of the newly-established Victoria Dental Hospital the financial statement showed that there was a balance in hand on the year's work of £226, and now that it has issued an annual report and an audit of its accounts it will be eligible for a grant from the Hospital Sunday and Saturday Funds. The amounts collected this year for these two funds combined was, up to the 28th ult., £7224, being £4665 for the Hospital Sunday and £2559 for the Saturday Fund. These amounts show a little falling off from last year; but there will be a few more sums yet to come in. Unfortunately, Hospital Sunday this year was a very wet day, and that may have influenced the result. It has been pointed out that our Saturday collection does not equal that of other similar populations, and that if it were made in a more systematic or revised manner the returns from this source might be considerably augmented.

THE MEDICO-ETHICAL SOCIETY.

At the last meeting of the above Society the newly-elected President, Mr. Walmsley, gave a short address on the present and future position of the Society, and in his remarks alluded to many matters which he thought might fairly claim attention. A somewhat animated discussion ensued, bearing especially on the illegitimate practice of medicine by unqualified men, and the unprofessional conduct of legally qualified men in connexion with the same. This evil would appear to be on the increase, and it was resolved that the special attention of the committee be directed to that subject during the ensuing year. Another matter set down also for early consideration was the relation of medical men in regard to coroner's inquests, more particularly the conducting of post-mortem examinations.

THE SALLORD GUARDIANS AND THE MEDICAL STAFF OF THE NEW HOSPITAL.

The new hospital at Hope belonging to the Salford Guardians has been rather prominently before the public of late: some of the members of that board have been bringing forward rather serious charges against the medical administration. First, it was stated that at some Christmas festivities held there patients were neglected while these were proceeding, and that they were prolonged too far into the night; and a resolution has been passed by which such festivities in the future will be very much curtailed. Still more recently, on the application of some of the members of the same board, a Local Government Board inquiry has been held to inquire into certain allegations made against the medical superintendent; but, so far as appeared from the published reports of the inquiry, the charges were not of a very serious character. The decision of the Local Government Board has not yet been received. Last week an animated discussion took place as to the administration of alcoholic stimulants by the medical staff, some of the guardians wishing to go so far as to prohibit their use altogether, until it was pointed out that they would be exceeding their powers to endeavour to carry into effect any such resolution.

Dr. William Roberts is at present delivering a weekly series of lectures, at Owens College, upon "Dyspepsia and Dietetics," which are open to all members of the profession, and to students in the medical department. They have been very numerously attended. As they will, in all probability, be published at their conclusion, further notice of them in these columns is unnecessary.

Dr. Morrison Watson, who was seized with an apoplectic attack at the College three weeks ago, has so far recovered as to permit of his removal to a private nursing institution, but his condition is still one of exceeding gravity.

Manchester, March 3rd.

NORTHERN COUNTIES NOTES.

(From our own Correspondent.)

NORTHERN COUNTIES CHEST HOSPITAL.

THE annual meeting of this institution was held last week, the Mayor of Newcastle presiding. The report showed that of 541 out-patients under treatment during the past year 143 had been cured and 387 relieved. Of the 22 in-patients, 1 was cured, 19 were relieved, and 2 died. The financial condition of the hospital was shown to be satisfactory, but the committee in the present state of trade could not venture on any extension of the premises, though very desirable, as it would involve an expenditure not covered by the present income.

NEWCASTLE CLINICAL SOCIETY.

The Newcastle Clinical Society gave its second annual banquet at the Central Station last week. Nearly forty sat down to a well-spread table, and the proceedings altogether were very spirited and harmonious. Dr. Mearns of Gateshead presided, and he was awarded well-deserved encomiums as ruler of the feast. Dr. Napier (Dunbar) and others made capital speeches.

TYNE PORT SANITARY AUTHORITY.

Some interesting statistics are afforded in the report of the Tyne Sanitary Authority for the past year. The number of ships during the year was 12,078, of which 9505 were British. The sanitary condition of 9425 of these was good, of 2152 "passable," of 501 defective. The total number of crews visited by the inspectors was 135,938, and of passengers, a large proportion of whom were emigrants, 9468. The measures taken by the authority to suppress the smoke nuisance on the river had brought about some improvement. The medical officer (Mr. H. E. Armstrong) stated that there had been a decrease of patients admitted to the floating hospital during the year as compared with 1883. It was decided at the same meeting to adopt the plan submitted by the city engineer for a new floating hospital on pontoons, in preference to the conversion of an old war-ship, which, even if the vessel were got without price, would involve an expenditure of at least £2000.

NEWCASTLE HOSPITAL FOR CHILDREN.

The annual meeting of the governors of the Hospital for Sick Children was held last week, under the presidency of Sir W. G. Armstrong. The number of in-patients—156 new cases—was stated to have been the largest on record; but there has been a slight decrease in the number of attendances of out-patients, which was still very large, representing no less than 6275 separate attendances on the physicians and surgeons. A vote of condolence with Dr. William Murray, consulting physician to the hospital, and who has been intimately connected with it since its commencement, on the great domestic affliction he has lately sustained by the death of his wife, was unanimously carried. The question of providing a convalescent institution was again brought forward for consideration, and may be said to have advanced a step; for, on the suggestion of Sir W. Armstrong, it was referred to a committee to report upon.

EPIDEMIC OF MEASLES AT SUNDERLAND.

There has been a severe epidemic of measles at Sunderland, causing a marked rise in the death-rate—viz., 37·7 per 1000. Of 91 deaths in the week, 26, all children, were due to measles alone. There were 20 deaths from chest diseases, and many of these cases are supposed to have been unrecognised measles. Mr. Harris, the medical officer of health, has taken very active measures to arrest the spread of the epidemic, in the way of ventilation and disinfection of the public schools.

Mr. Frederick Page, one of the surgeons to the Newcastle-on-Tyne Infirmary, and a lecturer here, has been appointed Assistant Examiner in Clinical Surgery to the University of Edinburgh.

Newcastle-on-Tyne, March 2nd.

THE Corporation of Exeter propose to light the new asylum now in course of erection with the electric light. The building is to accommodate 300 patients.

IRELAND.

(From our own Correspondent.)

QUEEN'S COLLEGES, IRELAND, COMMISSION.

CONSIDERABLE dissatisfaction has arisen in consequence of a solitary newspaper in Ireland having been favoured with a report of the Commission held last year in reference to the condition of the Queen's Colleges in Ireland. The matter has very properly been brought before Parliament, and it has been elicited from the Chief Secretary that the journal in question obtained the information it published from one of the commissioners. It is a strange occurrence that even up to the earlier part of this week the Queen's printer in Dublin could not supply a copy of the report, and the President of the Belfast College recently wrote to ask information as to where he could obtain one, as it so deeply concerned his own institution. The action of the commissioner in question must be regarded as a breach of parliamentary privilege. The report of the majority of the five commissioners—viz., Mr. G. J. Stoney, F.R.S., Professor Jack, LL.D., and Deputy-Surgeon-General Marston, M.D.—is a very elaborate document, covering nearly sixty pages. In addition to the suggestions referred to in last week's issue, these gentlemen recommend the following:—"That, as at present, non-matriculated students shall be admitted to the Colleges. That the matriculation examination programme in arts and law in Cork and Galway be made practically equivalent to that of the Royal University. That the Colleges be permitted to enter students entitled to compete for scholarships in medicine and engineering on a different programme, designed in view of the requirements of those professions. That the Colleges should admit students who have passed the first university examination in arts in the Royal University to compete with their students for the scholarships at the beginning of the second year, subject to the usual conditions of residence. That the senior scholars should be freed from the duty of teaching, which tends to diminish the competition for the scholarships and their practical value. That in Galway medical scholarships shall cease to be awarded in the third and fourth years. That summer classes be instituted in Cork, as in Belfast, for the benefit of medical students. That the distribution of the scholarships be reconsidered with a view to making some difference in the amount payable to the scholars according to their places in the list, and with a view to transferring unawarded arts scholarships to medical students where the number of probable competitors seems to warrant it." As regards the clinical facilities available to the students in medicine, they state that in none of the Colleges are they quite satisfactory. In their judgment they are best in Belfast, very fair in Cork, but certainly inadequate in Galway. In all of them some improvement might be effected. To sum up, the majority of the commissioners state that in their opinion the general standard of education maintained in the Queen's Colleges is in the main satisfactory.

DEATH OF DR. MARCUS EUSTACE.

I record, with regret, the death of this gentleman, which took place at Elmhurst, Glasnevin, on the 1st inst., from cardiac disease. The deceased, who was only fifty-three years of age, was engaged in the treatment of mental affections, and was the proprietor of a private lunatic asylum at Glasnevin near Dublin, and the author of various communications bearing on insanity. Dr. Eustace was a Fellow of the College of Physicians in Ireland, and his decease will be much regretted by a large circle of friends, who esteemed him highly.

THE LABOURERS ACT (IRELAND).

A considerable amount of uncertainty has existed since the passing of this Act as to whether medical officers who had to inspect labourers' dwellings were entitled to extra remuneration for their services. Some time since Dr. Rogers of Youghal sued, at the instance of the Irish Medical Association, the Youghal guardians for a sum of £36 3*s*., and a verdict in his favour was obtained. The guardians brought the case, however, into the Court of Exchequer, when it was ruled that, as the duties were performed by Dr. Rogers in his capacity of medical officer of health, he was not entitled to recover the fees, with the exception of an outlay for car hire. From this decision a

further appeal was taken, and last week, before the Lord Chancellor and Lord Justices Barry and Fitzgibbon, it was finally decided that the plaintiff was entitled to the sum claimed, inasmuch as the duties for which remuneration was asked had not been assigned to him by the Local Government Board. The appeal was allowed, with full costs.

Dr. F. MacCabe of the Local Government Board has been appointed a Medical Commissioner under the Irish Prisons Board.

Dublin, March 3rd.

PARIS.

(From our Paris Correspondent.)

THE PARIS FACULTY OF MEDICINE.

THE Summer Session of the Paris Faculty of Medicine begins on the 16th inst., and will be continued in the following order: — Medical Natural History, Professor Baillon; Physiology, Professor Béclard; Surgery, Professor Guyon; Medical Jurisprudence, Professor Brouardel; Pharmacology, Professor Regnauld; Pathology and General Therapeutics, Professor Bouchard; Medicine, Professor Damaschino; Experimental and Comparative Pathology, Professor Vulpian; Hygiene, Professor Bouchardat; Materia Medica and Therapeutics, Professor Hayem; Clinical Medicine at the Hôtel Dieu, Professor Germain Sée; Clinical Medicine at La Charité, Professor Hardy; Clinical Medicine at the Hôpital Necker, Professor Potain; Clinical Medicine at La Pitié, Professor Jaccoud; Clinical Surgery at the Hôtel Dieu, Professor Richet; Clinical Surgery at La Pitié, Professor Verneuil; Clinical Surgery at La Charité, Professor Trélat; Clinical Surgery at the Hôpital Necker, Professor Le Fort; Mental Pathology and Diseases of the Encephalon at the Sainte Anne Asylum, Professor Ball; Clinical Diseases of Children at the Hospital for Diseases of Children, Professor Grancher; Syphilitic and Cutaneous Affections at the Hôpital Saint Louis, Professor Fournier; Clinical Diseases of the Nervous System at the Salpêtrière, Professor Charcot; Clinical Ophthalmology at the Hôtel Dieu, Professor Panas; Clinical Obstetrics at the Clinic of the Faculty of Medicine, Professor Pajot. Besides his lectures at the School of Medicine, Professor Brouardel delivers a practical lecture three times a week at the Morgue. In addition to the above lectures, the following is a list of the principal supplementary lectures that will be delivered in the course of the session:—Medical Chemistry: Dr. Hanriot, agrégé. Natural History: Dr. Blanchard, agrégé. Physics: Dr. Gariel, agrégé. Physiology: Dr. Rémy, agrégé. Morbid Anatomy: Dr. Straus, agrégé, who will lecture on the Anatomical Lesions determined by Microbes, the Morbid Anatomy of the principal Infectious Diseases, &c. Practical lectures, with demonstrations and experiments, will also be delivered on Chemistry, by Dr. Hanriot; Physics, by Dr. Guébhard; Physiology, by Dr. Laborde; Histology, by Dr. Cadiat; Operative Surgery, by Dr. Farabeuf.

PRIZES AT THE ACADEMY OF SCIENCES.

At the annual meeting of the Academy of Sciences, which was held last week, the following prizes for the year 1884 were announced, but I give only those concerning medicine and its collateral branches:—M. Alfred Durand-Claye, for his work on the Epidemic of Typhoid Fever in 1882. Honourable mention was accorded to M. Chervin for his memoir on the Medical Geography of the Seine-Inférieure. The Prix Montyon was divided among three candidates, 2500 francs being awarded to each: the first to M. Testut for his treatise on Muscular Anomalies in Man explained by Comparative Anatomy; the second to M. Cadet de Gassicourt for his clinical treatise on Diseases of Children; the third to M. Leloir for a series of memoirs on Cutaneous Affections. The Prix Godard was awarded to M. Tourneur for his researches on Embryonic and Fœtal Anatomy. The Prix Serres was divided between Dr. Cadiat for his treatise on General Anatomy applied to Medicine, and M. Kowalevsky for his works on Embryogeny. The Prix Sallemann was awarded to Professor Brown-Séquard for his series of works on Inhibition and Dynamogeny. Another portion of the Prix Montyon was divided between MM. Jolyet and Laffont for their researches on the Vaso-dilator Nerves. The Prix Ponti was awarded to M. Joseph Boussingault for his work on Fermentation.

Paris, March 3rd.

VIENNA.

(From our own Correspondent.)

TUBERCULOSIS IN VIENNA.

WHILST through the salutary influence of the "Hochquellen" aqueduct, which supplies Vienna with drinkable water from the Styrian Alps, the cases of diseases of the stomach and of the intestine have considerably diminished and cases of typhus have become rare, the number of phthisical persons increases every year. The number of people who yearly die in Vienna from phthisis pulmonalis is not less than 5000, and according to the last report of the Vienna "Allgemeines Krankenhaus" in this hospital alone 18,096 patients suffering from pulmonary diseases sought relief during the last decennium, of whom 10,172, that is 562 per cent., died. Doubtless the dust of our granite pavement is the cause of much pulmonary disease, but certainly other social circumstances contribute largely to the spread of the affection. The Austrian Home Minister recently instructed the authorities of the various hospitals to take into consideration the advisability of separating patients suffering from phthisis pulmonalis from the other patients, and to adopt any other precautionary measures which might be deemed necessary. The answers have not yet been returned.

VAGUS PNEUMONIA.

The changes in the lungs caused by cutting through the vagus nerves have formed since the time of Valsalva the subject of very deep research. All animals whose vagi have been divided in the throat perish sooner or later. Most of them die of broncho-pneumonia. Traube is of opinion that this vagus pneumonia is caused by the penetration of mucus and of food-matters into the trachea. Schiff, however, gave the following explanation: The vagus is the nerve which supplies the muscles of the vessels of the lung; if it is severed, paralysis of the muscles with hyperæmia and inflammation occur. In order to decide the controversy, only the branches of the vagus which proceed to the lungs should be cut through, whereas the recurrent laryngeal nerves must remain intact. Dr. Gärtner and Dr. Amrüs have, in Professor Stricker's laboratory, cut through the vagus below the recurrents after two methods. According to the first, they divide the recurrent laryngeal in the neck, and connect it with the vagus at the throat, where it heals up, after which they cut through the vagus below this spot. A dog which was thus operated on on both sides died after sixteen days, and showed no broncho-pneumonia at the autopsy. The second method is more exact. The pleural cavity is opened, and then resection of the vagus is performed under antiseptic precautions. The branches proceeding to the heart and to the larynx remain intact, and only those branches are divided which supply the lung and stomach. A dog in which, on the thirtieth day after the operation, a gastric fistula was produced, perished on the forty-sixth day, obviously owing to the latter operation. At the autopsy no pneumonia could be detected; the lungs were pale, without the slightest infiltration. Consequently the question of vagus pneumonia is definitively settled according to the views of Traube.

A CORN-GRAIN IN THE MUSCLE OF THE HEART.

Dupuytren and Balch relate cases in which bullets have remained embedded during several years in the substance of the right side of the heart without producing obvious disturbance. Carnocha has also reported a similar instance affecting the ventricular septum. The following case will, however, be found none the less worthy of interest. On Nov. 19th of the past year, a locksmith, aged thirty-four, happened to discharge a gun loaded with hail-shot against the left side of his thorax. He walked without any support to the hospital, distant an English mile. The hail-shot entered about one centimetre below and one centimetre and a half to the inner side of the nipple. The patient coughed and spat blood. The left side showed dulness as far as the middle of the scapula. On the next day dulness of the entire left side of the thorax was noted, which was referred to hæmothorax. After the lapse of seven days pleuritis supervened, and twenty-one days after the accident the thorax was punctured owing to urgent dyspnœa,

when 500 centimetres of a bloody liquid were discharged. After another seven days thoracentesis had to be performed, as the dyspnœa had become very urgent, when two litres of dark putrefying blood were discharged. Into the pleural cavity about two tablespoonfuls of a thin emulsion of iodoform were poured; a drainage-tube was inserted, bandages applied, and the wound healed well. At the beginning of January symptoms of Bright's disease were remarked, from which the patient died on Jan. 19th. At the autopsy an opening corresponding to the left ventricle, with pigmented borders, was found in the pericardium, and in the substance of the right chamber of the heart a grain of corn was embedded. Professor von Mosetig, in whose division this case occurred, stated that the substance of the heart showed no obvious change.

GASTRIC ULCER ASSOCIATED WITH DIPHTHERIA OF THE STOMACH.

Professor Kundrat exhibited in the last sitting but one of the I. a. R. Society of Physicians a rare preparation of an enormously dilated stomach, on the back and partially on the front wall of which, near the pylorus, an ulcer existed as large as the palm of the hand, the borders of which were of a spiral shape, and the whole of which was typical; the surrounding parts were discoloured and diphtheritic. The pylorus was lying sideways and narrowed in the form of a semilunar slit, the scarred retraction of the ulcer having dragged it towards the middle, whereby the antrum pyloricum was pushed forwards and the dilatation of the stomach continually increased. In consequence of the abnormal position of the pylorus, the symptoms of the stenosis multiplied. A diphtheritic condition of the mucous membrane of the stomach, which has been repeatedly observed in cases of diphtheria of the throat, even without involving the œsophagus, is a rare complication. Professor von Bamberger, at whose clinic the case in question occurred, stated that the decrepit patient, though only forty-four years of age, suffered for four years from severe indigestion and constipation. Vomiting took place, but no hæmatemesis. Blood-corpuscles could not be found in the vomited matters, whereas the Teichmann crystals could be distinctly seen. Free muriatic acid was lacking in the contents of the stomach, in spite of Van der Velden's and Riegel's statement that this want of muriatic acid is a sure symptom of carcinoma. The patient died of internal hæmorrhage.

OPERATION FOR TUMOUR OF THE BLADDER.

Sir H. Thompson, in his work on Tumours of the Bladder, has recommended perineal section to be made for the purpose of digital exploration of the bladder in cases of cystitis, in various kinds of cystodynia the cause of which cannot be found otherwise, and in cases of hæmaturia vesicalis of unknown origin. Herr Dr. Hofmockl adopted this method in the case of a very decrepit man, who showed strong symptoms of anæmia, and who had suffered for three years from hæmorrhage from the bladder, and, when the coagula prevented the flow from the urethra, also from ischuria. Dr. Hofmockl first found, by means of the catheter, a floating body on the right side of the bladder, which he believed to be a tumour of that viscus. By the performance of perineal section he succeeded in extracting a villous mass, which was connected with the bladder by a pedicle, and which proved to be a papilloma villosum. The pedicle was nearly wholly removed with the rasp spoon. The bleeding soon ceased. An iodoform bandage, no drainage, and injection with a solution of nitrate of silver (1 in 100) was the treatment adopted. The patient soon after the operation became apyretic, and the urine, which formerly was ammoniacal and cloudy, became of a clear bright yellow; but after the lapse of about three weeks he died of violent bleeding from the rectum, which was caused, according to the necropsy, by an ulcer in the duodenum. The rest of the pedicle could not be found in the bladder. Professor von Dittel states that he prefers, as a rule, to convince himself of the presence of a tumour by means of the Nitze-Leiter's electro-endoscope, and then to perform the supra-pubic operation, although Hofmockl's operation succeeded very well.

THE BACILLUS OF SYPHILIS.

The researches respecting the syphilis bacillus are now finished, and will shortly be published. Dr. Lustgarten attributes real diagnostic value to the proof of the existence of this organism. In sixteen cases of syphilis he succeeded in rendering visible this bacillus by a mode of decolourisation peculiar to itself. It is very similar to the tubercle bacillus, but always occupies a cell. In cases of sclerosis, gumma, and in the contents of syphilitic ulcers, the same micro-organism was found; in the soft chancre, however, the presence of a bacillus could not be proved.

Vienna, Feb. 13th.

Obituary.

WILLIAM GILLBEE, M.R.C.S.

MR. WILLIAM GILLBEE, one of the oldest practitioners in Melbourne, expired on Jan. 4th, aged sixty years. The deceased was born in Hackney and received his medical education at Edinburgh. In 1848 he became a member of the Royal College of Surgeons of England, and in the following year visited Tasmania and Victoria. Proceeding to California, he for two years lived an adventurous life in the wild gold-fields of that country. Returning to England, he again took ship for Geelong, and at once commenced practice in Melbourne. In the early part of 1854 he was elected surgeon to the Melbourne Hospital, then about one-tenth of its present size. With this institution his professional life was closely identified, and in every movement made to enlarge and improve it he took a very active share. He held the position of honorary surgeon to the institution for twenty-two years, till the election of 1875, when he was not one of the successful candidates. He, however, retained his place in the committee of the hospital, and in 1877 became its vice-president, and in 1882 its president. In 1853 he assisted in the formation of the Medical Society of Victoria, of which, ten years later, he became president. In 1879 he warmly assisted in the formation of the Victorian branch of the British Medical Association, and was elected its first president. In 1872 he was elected by a vote of the whole profession to a seat on the Medical Board of Victoria, and about six years ago he was appointed its president, which office he held at the time of his death. The cause of his death was disease of the lungs, which a visit to England in 1883 had entirely failed to benefit.

Medical News.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—At examinations held last week the following gentleman was admitted a Fellow of the College:—

Frederick Heuston, A.M.D.

APOTHECARIES' HALL.—The following gentlemen passed their examination in the Science and Practice of Medicine, and received certificates to practise, on the 26th ult.:—

Arnold, William, Manchester School of Medicine.
Blachford, Jem, London Hospital.
Cundell, William Hatch, St. Mary's Hospital.
Hebblethwaite, Septimus Montague, St. Bartholomew's Hospital.
Innes, Charles Barclay, St. Bartholomew's Hospital.
Sutton, James Bryan, Charing-cross Hospital.

DR. T. J. MACLAGAN has been elected a member of the Royal Institution.

PNEUMONIA has lately been unusually prevalent and fatal in New York.

QUARANTINE is now imposed at Alexandria on all arrivals from Bombay and Madras.

A TELEGRAM from Paris states that the Ecole Normale has been closed on account of several cases of typhoid fever.

AT the annual festival of the Earlswood Asylum for Idiots held on the 3rd inst., subscriptions to the amount of £1518 were announced.

RIVER POLLUTION.—A deputation from the National Society to Secure Effective Legislation against River Pollution waited upon the Lord Mayor on the 3rd inst., and arranged for a public meeting at the Mansion House, under his lordship's presidency, at an early date.

TYPHUS FEVER is reported to be rife at Kieff, which is at present crowded by persons attending the fair for negotiating beetroot contracts.

THE Home for Incurables at Aubert-park, Highbury, which has been erected at a cost of £4000, and is intended to accommodate forty patients, was opened on the 4th inst.

THE tender of £74,571 submitted by Messrs. Kirk and Randall, for the erection of a new infirmary at Championhill, has been accepted by the guardians of the St. Saviour's Union.

DR. W. O. THRAILKILL of San Francisco communicates to a recent number of the *Philadelphia Medical World* the discovery at Point Sal in Santa Barbara county of a male and female petrifaction.

THE Gillingham (Kent) Local Board have at length decided to erect an infectious disease hospital for the parish, and are advertising for two or three acres of land for that purpose.

THE workhouse and infirmary in connexion with St. George's-in-the-East Union are about to be enlarged, at a cost of £9500. Messrs. Wilson, Son, and Aldwinckle are the architects.

VACCINATION GRANTS.—Mr. J. Payne Massingham of the Wolstanton district, Mr. H. Whiting of Haslemere, Mr. D. Mackintosh of Downham, and Mr. J. Hamilton of Swadlincote, have received Government grants for efficient vaccination.

MR. WILLIAM RUSSELL, of Barnwell, Northampton, has given £5000 to the authorities of the University of St. Andrews to found entrance bursaries in memory of his brother and himself, both having received their education at that university.

THERE is a difference of opinion in Ramsgate about the merits of the corporation drainage scheme, a somewhat noisy meeting having been held for the purpose of opposing it and substituting a plan suggested by Mr. H. J. Johnstone, J.P.

PRESENTATION.—Dr. Henry Tomkins, late resident medical officer of the Monsall Fever Hospital, has been presented with a handsome dressing-case by the nurses and others of the staff of that institution, on his resignation after a tenure of office of more than six years.

THE ASSOCIATION OF PUBLIC SANITARY INSPECTORS.—At the monthly meeting of this Association, to be held to-day (March 7th) at 6 P.M., at 1, Adam-street, Adelphi, an address will be delivered entitled "Disinfectants and their Sanitary Uses," by Dr. John W. Tripe, medical officer of health for the Hackney District.

THE Dover Board of Guardians have increased the salary of Dr. Finn, the surgeon to the workhouse, from £100 to £130, Alderman Dr. Marshall bearing witness from his own knowledge to the efficient manner in which the duties had been carried out. It was stated at the board meeting that the work had increased considerably, and that there were now 113 patients in the workhouse hospital.

MAINTENANCE OF SMALL-POX PATIENTS. — The Woolwich Board of Guardians have sued a man whom they sent with his own consent to the small-pox hospital for 1*s.* a day. The judge asked to be referred to an Act giving boards of guardians power to recover for maintenance of a patient removed by them to a hospital. As such an Act could not be produced the Board were non-suited.

DRINKING-WATER CONDENSING MACHINERY FOR EGYPT.—The *Calabria*, a telegraph ship chartered by the Admiralty for the Egyptian expedition, is (says the *Engineer*) fitted with the largest installation of condensing machinery ever put in one ship. It is for the purpose of converting sea-water at Suakim into drinking-water for the troops and other persons connected with the expedition. It is capable of condensing 64,000 gallons a day; and is very simple in construction, only occupying a deck space of 21 ft. by 18 in., and weighing 33 cwt. The enormous cable tanks will contain 750 tons of water, and these are supplemented by forty-eight 400-gallon tanks, so that a very large quantity can be sent on shore in boats at once.

HOMES FOR INEBRIATES.—At the recent annual meeting of the Homes for Inebriates Association it was stated that in the Dalrymple Home there had been forty-nine admissions, and of those discharged 50 per cent. were doing well, and 25 per cent. were improved. The majority had been admitted under the provisions of the Habitual Drunkards Act, nine having entered for twelve months each. The sum of £15,000 is solicited for a Home for the Poor.

PROVIDENT SURGICAL APPLIANCE SOCIETY.—At the thirteenth anniversary festival in aid of the funds of this institution held on the 27th ult., it was stated that since its establishment nearly 35,000 persons have been relieved by the Society, which last year treated 4151 cases. The annual expenditure exceeds £1700, of which about £1100 represents the cost of instruments, to which patients contribute £500, the remainder of the funds being supplied by subscriptions and donations, which are much needed.

TESTIMONIAL TO DR. DENHAM, OF DUBLIN.—The fund which has been formed in Dublin for the purpose of presenting Dr. Denham, a well-known obstetric surgeon of that city, with an address and testimonial on the occasion of his retiring from practice, has reached £370, and will shortly be closed. In the meantime any of the pupils or friends of Dr. Denham who wish to subscribe and have their names added to the list should communicate without delay to Dr. Kidd, hon. treasurer, 58, Merrion-square, Dublin.

DEATH OF DR. DAMROSCH.—News has been received from New York of the sudden death from pneumonia and overwork of Dr. Leopold Damrosch, who was born at Posen in 1832, and took his degree as Doctor of Medicine at Berlin University. He afterwards studied music, and became a member of the Weimar orchestra under Liszt. He resided for many years in Breslau, but in 1871 he went to New York, where he organised the Oratorio Society, the Symphony Society, the May Festival, and lastly a season of German opera, which is still in progress.

SEAMEN'S HOSPITAL SOCIETY.—The sixty-fourth annual court of this Society was held on the 4th inst. From the report, which was read and adopted, it appears that the number of patients under treatment in the hospital last year was 1751, and that 7360 out-patients were relieved. The drainage of the hospital has been found to be so radically defective that nothing short of the reconstruction of the whole system can place the hospital in a safe sanitary condition. The estimated cost of the drainage works is £3000, and towards this the Lords Commissioners of the Admiralty have agreed to contribute £1500.

LONDON SANITARY PROTECTION ASSOCIATION.—At the annual meeting of this Association, which was held on the 28th ult. at their offices, 1, Adam-street, Adelphi, Lord Chelmsford (who took the chair in the absence from town of the President, the Duke of Argyll) announced that the number of members was now close upon 1000, having been 887 on Dec. 31st last. This number included about forty medical men who were members in respect of their own private residences. The annual report, which had been circulated, showed that there were now fourteen Associations working in the country on exactly the same principles as the London one, and mustering 2356 members on Dec. 31st; and that in the course of the year the engineers of the London Association had reported upon the sanitary arrangements of four of the smaller London hospitals and one large hospital at Chatham.

THE FOOD AND DRUGS ACT.—A case under this Act was heard recently before the Greenwich magistrate where the secretary to the Seamen's Hospital, who had contracted for a supply of milk with 10 per cent. of cream all the year round, noticing the continued poorness of what was supplied, took a sample, "telling the defendant's man it was for analysis. He divided it into three parts, giving one to the man, keeping another himself, and sending the third to the public analyst." A certificate was handed in which stated that 60 per cent. of cream had been removed, and that there had been about 5 per cent. of water added. The magistrate then asked whether he had explained to the man that he was going to have the sample "analysed by the

public analyst." The prosecutor replied that he had said it would be analysed. This, his worship decided, was fatal to the case, and dismissed the summons. He refused, however, an application for costs, though the defendant's solicitor stated that he had half a dozen grounds of defence.

MEDICAL SOCIETY OF LONDON.—The following is a list of officers and Council elected for the ensuing session:—President: William Miller Ord, M.D. Vice-Presidents: Richard Douglas Powell, M.D.; Sydney Jones; John Langdon Down, M.D.; Samuel Cartwright. Treasurer: Arthur Edward Durham. Librarian: William Henry Allchin, M.B., F.R.S.E. Honorary Secretaries: James Kingston Fowler, M.D.; John Henry Morgan, M.A. Secretary for Foreign Correspondence: Felix Semon, M.D. Council: Thomas Lauder Brunton, M.D., F.R.S.; Smith Houston Davson, M.D.; Sir Joseph Fayrer, K.C.S.I., M.D., F.R.S.; David W. Finlay, M.D.; Alfred Pearce Gould, M.S.; F. De Havilland Hall, M.D.; Francis Mason; Edmund Owen; Isambard Owen, M.D.; George Richard Turner Phillips; Thomas Pickering Pick; Walter Pye; Joseph Peeke Richards; Arthur Ernest Sansom, M.D.; Charles Brodie Sewell, M.D.; William Heath Strange, M.D.; T. Tillyer Whipham, M.A., M.B.; William Henry White, M.D.; Charles Theodore Williams, M.A., M.D.; Alfred Wiltshire, M.D.

WESTMINSTER HOSPITAL MEDICAL SCHOOL.—The corner stone of the new buildings for this institution, now in course of erection in Caxton-street, was formally laid on the 28th ult. by the Duke of Westminster. The building, which is in the Queen Anne style, is 160 ft. long, and is four storeys high. The site on which it stands is next to the Westminster Town-hall, and was acquired at a cost of £4000, while the building and fittings are estimated to amount to £10,000. It has been erected for the purpose of relieving the hospital, where the medical school has heretofore been carried on, and the space thus left vacant in the former will be utilised for extending the present out-patient accommodation. The new school will give room for the attendance of about 200 students, and is provided with all the necessary class-rooms, laboratories, and lecture-rooms, besides a refreshment and recreation department, and an extensive specimen museum. It is anticipated that the school, which is being constructed in red brick, with red Corshill stone facings, will be ready for use in October next.

Medical Appointments.

Intimations for this column must be sent DIRECT *to the Office of* THE LANCET *before 9 o'clock on Thursday Morning at the latest.*

BADDELEY, CHARLES EDWARD, M.B.Lond., M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for the First District and Workhouse of the Newport (Salop) Union, vice Thomson, resigned.

BUNDY, A. ST. CLAIR, F.R.C.S., has been appointed Assistant-Surgeon to the Western Ophthalmic Hospital.

DAVIES, EDWARD, M.D. St. And., M.R.C.S., L.S.A.Lond., has been reappointed Medical Officer of Health for the No. 2 Wrexham Rural Sanitary District.

FOX, W. PIERCY, L.R.C.P. &c., has been appointed Assistant Medical Officer to the Brownlow-hill Infirmary, Liverpool, vice J. Henderson Brannigan, resigned.

GABB, J. PERCY A., M.D.Lond., has been appointed Honorary Assistant Medical Officer to the Royal Surrey County Hospital, Guildford, vice H. Parson, resigned.

HARFORD, EDW. AUGUSTUS, L.R.C.P.Ed., M.R.C.S., has been appointed Medical Officer for the First District of the Newcastle-on-Tyne Union, vice Scotland.

JONES, WILLIAM, L.R.C.P.Ed., M.R.C.S., L.S.A.Lond., has been reappointed Medical Officer of Health for the Ruabon District of the Wrexham Union.

LAPAGE, CHAS. CLEMENT, M.A., M.D.Cantab., has been appointed Physician to the Nantwich Brine and Medicinal Baths Company.

LEACH, ALFRED, L.R.C.S.E., L.S.A.Lond., has been appointed Attending Medical Officer and Accoucheur to the Provident Medical Institution and Free Dispensary, Pimlico-road, S.W., vice Arthur Graham, retired.

MORGAN, THOMAS W. LUVELL, M.R.C.S., L.S.A.Lond., has been appointed Medical Officer for No. 3 District of the Newport (Salop) Union, vice Baddeley.

OLDHAM, H. FALCONER, B.A., M.B., B.Ch. Trin. Coll. Dub., Resident Medical Officer to the Netherfield Institution for Infectious Diseases, Liverpool, has been appointed Resident Medical Officer to the Monsall Fever Hospital, in connexion with the Royal Infirmary, Manchester, vice H. Tomkins, M.D., resigned.

PALM, THEODORE A., M.D., C.M.Ed., has been appointed Medical Officer for the Thorncombe District of the Axminster Union, vice Wills, deceased.

PERKS, Dr. ROBERT HOWELL, F.R.C.S.E., has been appointed Resident Medical Officer to the Royal Albert Hospital, Devonport.

STEPHENS, WILLIAM J., L.R.C.P.Ed., has been appointed Honorary Physician to the Brighton and Hove Dispensary, vice E. G. Whittle, M.D.Lond., resigned.

STEVENS, ARTHUR FREDERICK, M.R.C.S., has been appointed Medical Officer for the First District of the Thingoe Union, vice Masters, resigned.

THOMSON, T. P., M.B. & C.M., has been appointed Medical Officer and Public Vaccinator for the Alberbury District of the Atcham Union, vice Lawson, M.R.C.S., resigned.

WATSON, ARCHIBALD, M.D., F.R.C.S., has been appointed Professor of Anatomy in the Adelaide University.

WEST, WILLIAM AUGUSTUS, L.K.Q.C.P.I., L.R.C.S.I., has been appointed District Surgeon of the Sydney Hospital.

WHITE, JOHN WILLIAM, L.K.Q.C.P.I., L.F.P.S.Glas., M.R.C.S., has been appointed Medical Officer for the Fifth District of the Bedminster Union, vice Cory, resigned.

WOOLERTON, EDWIN GOODBURN, L.R.C.P.Ed., L.R.C.S.Ed., has been appointed Medical Officer for the Wendover District of the Wycombe Union, vice Odling, resigned.

Births, Marriages, and Deaths.

BIRTHS.

HEPBURN.—On the 23rd ult., at 3, Bridge-road, Hammersmith, W., the wife of John Hepburn, L.R.C.P. &c., of a daughter.

JULER.—On the 2nd inst., at Wimpole-street, Cavendish-square, W., the wife of Henry Juler, F.R.C.S., of a daughter.

MICHAEL.—On the 1st inst., at Turnchapel, Plymouth, the wife of Surgeon H. J. Michael, Medical Staff, of a daughter.

WEST.—On the 24th ult., at Wimpole-street, Cavendish-square, W., the wife of Dr. Samuel West, of a daughter.

MARRIAGES.

CAMERON—SAVORY.—On the 3rd inst., at Stephen's Church, Westbourne-park, Robert Duncan Cameron, L.R.C.P. & L.R.C.S., of North Cave, Brough, Yorkshire, second son of Donald Cameron, LL.D., M.A., of Torquay, to Grace, daughter of the late William Savory, Esq., of Painswick, Gloucestershire.

CROOKSHANK—COLFOX.—On the 26th ult., at Bridport, Dorset, Edgar March Crookshank, M.B.Lond., youngest son of the late Captain Chichester Crookshank, 51st Foot (King's Own), to Harriet, only child of Thomas Colfox, Esq., J.P., of Rax House, Bradpole, Dorset.

CURD—DOYLE.—On the 26th ult., at St. Paul's, Camden-square, Charles Curd, M.R.C.S., of Bath, to Charlotte Emily, second daughter of Watkin Doyle, of Camden-road, N.W.

GILKES—DUNN.—On the 25th ult., at St. Augustine's, Highbury New-park, Norton Gilbert Gilkes, M.R.C.S., of Walthamstow, to Catherine Mabel, elder daughter of the late George Dunn, M.R.C.S., of Hales Owen, Worcestershire.

DEATHS.

BROWNE.—On the 2nd inst., at Crindan, Dumfries, W. A. F. Browne, M.D., LL.D., F.R.C.S.E., late Her Majesty's Commissioner in Lunacy for Scotland, in his 79th year.

GELL.—On the 29th December, 1884, at Thornborough, Queensland, suddenly, of apoplexy, Thomas Silvester Gell, M.D.Edin. (1870), M.B. & C.M. (1866), M.R.C.S.Eng. & L.S.A. (1866) Univ. Edin., late of St. John's Lodge, Kensal-green, aged 40.

HALPIN.—On the 27th ult., at Arklow, county Wicklow, Stopford W. Halpin, F.R.C.S.Eng. &c., aged 61.

HOPKINS.—On the 1st inst., after a long and painful illness, borne most patiently, at 93, Camberwell-road, Camberwell, S.E. (the residence of his brother, Dr. John Hopkins), Rees Hopkins, L.R.C.P., M.R.C.S.E., L.S.A.Lond., L.M., & M.R.C.V.S.Eng., of The Ash Grove, Pontypridd, Glamorganshire, in his 40th year.

HOWARD.—On the 28th ult., at his residence, New Buckenham, Norfolk, Horace Fulcher Howard, Esq., M.R.C.S.Eng. &c., in his 56th year.

SHILLITOE.—On the 1st inst., Richard Rickman Shillitoe, F.R.C.S., of Hitchin, aged 65.

WILLING.—On the 2nd inst., at Wood-green, George Frederick Brutton Willing, L.R.C.P., M.R.C.S., L.M., aged 64.

WOOD.—On the 1st inst., at his residence, Franklin House, South Norwood-hill, Surgeon-Major William Edward Wood, late of Her Majesty's Indian Army, aged 68.

N.B.—*A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.*

Medical Diary for the ensuing Week.

Monday, March 9.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M. each day, and at the same hour.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M. each day, and at the same hour.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
MEDICAL SOCIETY OF LONDON.—8.30 P.M. Dr. Macpherson: History of the Use of Ipecacuanha in Dysentery.—Dr. Sydney Coupland: A case of Endocarditis.—Dr. Samuel West: Hæmaturia in Granular Kidney.

Tuesday, March 10.

GUY'S HOSPITAL.—Operations, 1.30 P.M., and on Friday at the same hour. Ophthalmic Operations on Mondays at 1.30 and Thursdays at 2 P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M., and on Friday at the same hour.
ROYAL INSTITUTION.—3 P.M. Prof. Gamgee: Digestion and Nutrition.
ROYAL COLLEGE OF PHYSICIANS OF LONDON.—5 P.M. Dr. Hermann Weber: Croonian Lecture on the Hygienic and Climatic Treatment of Consumption.
ANTHROPOLOGICAL INSTITUTE OF GREAT BRITAIN AND IRELAND.—8 P.M. Mr. James G. Frazer: Certain Burial Customs as Illustrative of the Primitive Theory of the Soul.—Rear-Admiral F. S. Tremlett: The Sculptured Dolmens of the Morbihan.
ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—8.30 P.M. Mr. F. Treves: The Treatment of Acute Peritonitis by Abdominal Section.—Mr. J. R. Lunn and Dr. Benham: Case of Aneurism of Abdominal Aorta.

Wednesday, March 11.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M., and on Saturday at the same hour.—Ophthalmic Operations on Tuesdays and Thursdays at 1.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Skin Department: 9.30 A.M., on Tuesdays and Fridays.
ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M., and on Saturday at the same hour.
LONDON HOSPITAL.—Operations, 2 P.M., and on Thursday and Saturday at the same hour.
GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department: 1.45 P.M.; Saturday, 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M.
KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.
HUNTERIAN SOCIETY.—7.30. Council Meeting. Dr. Herman: Cases of Dermoid Pelvic Cysts.—Mr. Corner: Cases of Uterine Hæmorrhage with Impending Death cured by Removal of the Ovaries.
EPIDEMIOLOGICAL SOCIETY OF LONDON.—8 P.M. General A. C. C. De Renzy: The Prevention of Heat Apoplexy.
ROYAL MICROSCOPICAL SOCIETY.—8 P.M. Mr. J. W. Stephenson: A New Catadioptric Illuminator.—Dr. J. D. Cox: Structure of the Diatom Shell; Siliceous Films too thin to show a broken edge.—Exhibition of Nobert's Original Machine for Ruling his Lines.—Messrs. J. R. Cheshire and W. W. Cheyne: The Pathogenic History of a New Bacillus.—Mr. F. Fowke: The First Discovery of the Comma Bacillus.
BRITISH GYNÆCOLOGICAL SOCIETY.—8.30 P.M. Specimens by Drs. Aveling, Granville Bantock, Edis, and others.—President's Inaugural Address.—Dr. Aveling: A case of Double Pyosalpinx.

Thursday, March 12.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Surgical Consultations, 1.30 P.M.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.
CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.
NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ROYAL INSTITUTION.—3 P.M. Prof. Dewar: The New Chemistry.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editor."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for publication or private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe, or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "To the Publisher."*

"WHAT CONSTITUTES A QUALIFIED MEDICAL ASSISTANT."

The Birmingham Daily Gazette gives a report, under the above heading, of an action by Mr. Frederick Westwood against Mr. Ashmead to recover a certain sum for alleged services as assistant, over and above £30, received in form of advances, and £18 1*s*., the amount of a charge by Mr. Ashmead for medical attendance on Westwood. Mr. Ashmead's case was that he took Westwood merely for assistance in bookkeeping and dispensing, on the understanding that the experience gained would be sufficient remuneration to the assistant, whose sole medical qualifications were that he had while in America read a few medical books, the names of which he did not remember. Yet he said that he occasionally visited patients and prescribed for them. The judge thought the sums he had received were sufficient. The serious part of the case is that such persons should be allowed to act as assistants.

C. H. H.—We receive every week letters calling attention to discreditable advertisements similar to the one enclosed. To reproduce them would be to extend the publicity the delinquents desire.

Ajax.—There is nothing to prevent the officer from holding the appointment, providing the duties thereof are duly fulfilled.

Mr. G. Cowell.—Next week.

SCHOOL BOARDS AND MEDICAL CERTIFICATES.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Feb. 25th, 1882, the above subject was brought under notice by a letter from a medical man at Southwark, in which he wrote: "I hold in my possession a letter from the Education Department, Whitehall, ... confirming a statement previously made, that whenever a medical certificate is required by School Boards in explanation of the absence of a child from school, the cost of the certificate should be defrayed by the Boards themselves." In an annotation in the same number I read: "It is pleasant to find the imperious exercise of authority by School Board officials checked by magisterial interference..... If they [the children] are too ill to attend, the School Board would like to get that fact certified by the medical man in attendance. .....This attempt has been checked, we hope effectually, by a recent decision in the Southwark police-court, where the magistrate, Mr. Bridge, dismissed a summons obtained by the School Board and mulcted the Board in costs." Will you tell me, and, I may say, the profession, if you have any reason to alter your opinion on this subject? I hold that a medical man's duty is solely to attend the sick, and I persistently refuse to certify. There is a difference of opinion between me and some members of the Board. I showed the number of your journal to which I have alluded; but that is no authority, in their opinion. I should much like your opinion, and that of others of the profession.—I am, Sir, yours faithfully,

Feb. 26th, 1885. M.R.C.S.E.

*** We adhere to our expressed opinion. When public authorities require professional opinions, they must learn to pay for them.—ED. L.

HISTORY OF SMALL-POX.

X. Y. Z. should read Sydenham, Gregory, and Sir Thomas Watson. As later accounts none are better than the reports of the medical officers of the metropolitan small-pox hospitals, such as one before us by Dr. Gayton, in pamphlet form. In this, 10,403 cases are analysed. It is published by Messrs. McCorquodale, Cardington-street, N.W.

Mr. R. L. Collings.—It is a question of time and means, as well as of ability. As a general rule, the more practicable course at present is to try for a Scotch degree.

X. will find in our present number an answer to his question.

"HYSTERICAL PYREXIA."

To the Editor of THE LANCET.

SIR,—In your last issue I notice an annotation with this title, containing a reference to a communication made by M. Débove to the French Académie de Médecine. For the sake of British clinical medicine, I desire to say that the existence of this hysterical pyrexia is well known in this country, and I am surprised to hear that it should be regarded as a novelty. I should be prepared to give plenty of evidence of its existence, and I consider the occurrence of hyperpyrexia in hysteria by no means uncommon. I send for your inspection the charts, some of them recorded hourly, of the temperature of a girl whom I had under observation for some time. She never presented any sign of organic disease, and certainly was in good health for some time after her discharge, though I have recently lost sight of her.

I am, Sir, yours very truly,

Birmingham, March 3rd, 1885. ROBERT SAUNDBY.

To the Editor of THE LANCET.

SIR,—If you think the following case bears upon your remarks under the above heading in the current number of your journal, it is at your service.

On Saturday last I was called to see a young lady whom I had some months before been treating for mitral disease of rheumatic origin, and who had for some weeks past been in much better health than usual, and not under treatment. The evening before I saw her she was reported to have been remarkably well, and had been for a rather long walk. When seen by me she was in bed, having been very ill all night, delirious, and shrieking with pain referred to her back. I saw her about 1 P.M. after the bad night. She was then insensible, and evidently suffering much from pain in the back, with hot skin and furred tongue. Temperature 104° F. Considering the attack hysterical, I gave her tincture of valerian, sal volatile, and spirits of nitrous ether, twenty minims of each every four hours. At night the temperature was unchanged, but the patient was sensible, and complained of the globus, and frowned decidedly; the pain in the back was severe; there was no rheumatic odour, but some perspiration. I gave ten grains of Dover's powder. The patient slept well, and in the morning the temperature was normal, and but for soreness and weakness she felt fairly well. At 8 P.M. the pain returned, and the temperature again reached 104° F. Dover's powder was again given, and was followed by a good night and normal temperature in the morning, since which improvement has been maintained, and the patient is now fairly well, having had no further rise in temperature. Of course, the mitral condition is unchanged.

I am, Sir, yours faithfully,

Exeter, Feb. 28th, 1885. JAMES CHEESE, L.R.C.P.L., &c.

Mr. Stephens.—Our correspondent was bound to attend to the order of the relieving officer, unless he had received special instructions to the contrary, in regard to these particular cases. Such being the case, he can recover his fee from the guardians by action in the county court, as, of course, they are answerable for the mistakes of their servants. As to the policy of so doing, that will, of course, depend upon the relationship of our correspondent with the guardians.

M.R.C.S.E., L.R.C.P.Edin. is referred to our advertising columns.

Dr. Tomkins.—In an early number.

UNUSUAL CAUSE OF CONSTIPATION.

To the Editor of THE LANCET.

SIR,—As I am not aware that absolute obstruction of the bowel from eating fresh figs has frequently occurred or been referred to, I think the following case may not be devoid of interest.

A short time since a boy of ten years of age was brought to me, his mother saying he was suffering from constipation of four days' duration. As the patient walked with difficulty, and complained of a good deal of pain about the anal region, I made a local examination, and found the anus loose and flabby, and occupied by a hard, dense mass of fig-pips, to which a good number were adherent about the buttocks. Finding it impossible to introduce an enema tube, I proceeded to remove the mass by scraping away with the fingers, the relaxed condition of the anus readily admitting two fingers, though the acute pain the patient suffered made it necessary to administer chloroform. I removed in this way half a pound (weighed) of fig-pips, besides many which were washed out afterwards by an enema. The whole lower bowel for several inches seemed quite paralysed by the distension to which it had been subjected. On the following day the patient seemed quite comfortable, and his bowels had acted. As I have heard nothing of him since, I presume he is well.

I am, Sir, yours truly,

Bexhof, O.F.S., Jan. 28th, 1885. ARNOLD H. WATKINS, M.D.

A NEW FORM OF BLOTTING SHEET AND OF MEDICAL ADVERTISEMENT COMBINED.

THE following curious little handbill requires explanation:—

"[*Please use this Blotting Sheet.*]

"THE CITY OF LONDON MEDICAL AND SURGICAL ASSOCIATION.—An annual subscription of one guinea entitles a member to consult either of the medical officers at their consulting-rooms, which are situated in the heart of the City, whenever necessary. Full particulars of the Secretary, H. D. H. Charlton, Esq., Mansion House Chambers, 13, Size-lane, E.C."

Dr. Thos. Browne.—We have more than once expressed our abhorrence of the style of advertising referred to.

"THE ARABS WOUNDED IN THE SOUDAN."

To the Editor of THE LANCET.

SIR,—Mr. Allbutt's inquiry, "through the medium of your valuable journal, whether any provision is made for the surgical and medical treatment of the brave Arabs wounded in the battles in the Soudan," sounds a trifle comic, and akin to a stretch of the Exeter Hall sentimentalism. Our *confrères* in the Army Medical Department have, we should think, quite enough to do to minister to the wants of those who are legitimately under their care. Surely, it is too absurd to suppose or expect that they should bestow "the same humane treatment" on "the brave Arabs" as on "our own wounded soldiers." Cases have been reported by special correspondents of the London daily papers in which the "same humane treatment" was being attempted and practised by our surgeons on wounded "brave Arabs," with the result that attempts were made by way of thanks on the lives of the medical gentlemen aforesaid. I do not mean to assert that members of our profession should keep aloof from such of the wounded of the enemy as by chance come under their observation; on the contrary, they have in almost all campaigns stretched out a helping hand to them. But a suggestion that "provision" should be made for the wounded "brave Arabs" is surely impracticable.

I am, Sir, yours truly,

Feb. 24th, 1885. JOHN LUCAS, M.D.

AWARDS AT THE HEALTH EXHIBITION.

To the Editor of THE LANCET.

SIR,—By request of Jury No. 9 of the late Health Exhibition we forwarded, at the commencement of last August, several filters, which the circular stated were "to be tested." They have just now been returned to us, and, to our astonishment, we find that they have not been tested, not a drop of water having ever been passed through them. You will understand that the nature of spongy iron renders it easy to affirm this with certainty. It appears almost unnecessary to point out that the only known way to test filters as to their sanitary merits consists in a chemical and microscopic comparison of water before and after filtration through them. Such testing can, indeed, have been the only reasonable object in retaining filters for almost seven months, extending far beyond the close of the Exhibition. Surely, nothing could show more clearly the hollowness of at least some of the awards by the jury. Will the committee or the jury allow this stigma to rest on them as a body, or will they name those who are responsible for the blunder?

I am, Sir, your most obedient servant

(For the Spongy Iron Filter Company),

March 3rd, 1885. T. G. L. MILLER, Manager.

A. D. (M——).—The letter was certainly not calumnious, but entered rather too minutely into personal characteristics.

APPLICATION OF MIDWIFERY FORCEPS.

To the Editor of THE LANCET.

SIR,—I beg to say, in reference to the correspondence of Mr. Lucas and Mr. Cartmel respecting an easy method of applying the forceps, that to overcome the difficulty in question, which has now and again been alluded to in your columns, I suggested some time ago to Messrs. Arnold and Son a modification of the instrument. I pointed out the desirability of having a hinge placed on the upper blade where it joins the handle. This would allow—first, the handle to be bent on the blade in an upward direction, as the concavity of the blade looks downwards; secondly, it would keep the instrument from the bed, thus allowing the axes of introduction to be varied at pleasure, and would afford a better lever for the nurse to hold, whilst her hand would be kept out of the way of the manipulator. The hinge by a simple mechanism could be fixed at any angle.

I am, Sir, yours faithfully,

Finsbury-park, N., Feb. 25th, 1885. JAMES MACMUNN.

THE LATE MR. CÆSAR HAWKINS.

To the Editor of THE LANCET.

SIR,—I have to thank your correspondent (see page 414) for the corrections concerning the necessarily brief sketch of the life of the late Mr. Cæsar Hawkins given in my Hunterian Oration. I shall gladly avail myself of them when the address is published. I say he was "partly" trained in the great Windmill-street School, because, as I mention, he was *also* "a pupil" at St. George's Hospital. Then, I do not say he lectured at the Windmill-street School "late in life," but "later"—that is, after he had been a student there. In other particulars I stand "corrected."

I am, Sir, yours obediently,

Savile-row, W., March 2nd, 1885. JOHN MARSHALL.

MEDICAL ETIQUETTE AT CRIEFF.

WE have a closely-written letter of eighteen pages from Dr. Thom, giving minutely his version of the cases in regard to which Dr. Gairdner complains of his behaviour. On two or three points his defence seems to us weak; but he shows that there is another side of the questions raised. Dr. Thom protests that he, too, takes Styrap's medical ethics for his guide, and he ends his letter by saying that he still considers it his duty to hand over to Dr. Gairdner any case he may see *for him* during his temporary absence from home. We are still of opinion that the matters in dispute should admit of friendly settlement, perhaps with the help of a mutual professional friend. The publication of such lengthy correspondence is out of the question.

Mr. G. Holifield.—R. Kimpton, 126, Wardour-street, W.

Dr. Milner Fothergill.—Yes.

ELECTRIC ILLUMINATION OF THE VARIOUS CAVITIES OF THE HUMAN BODY.

To the Editor of THE LANCET.

SIR,—In your report of the meeting of the Medical Society in your issue of the 28th ult. Dr. Gilbart Smith states that "the difficulty of warming the mirror was great when the electric lamp was used." I would suggest that the mirror be smeared carefully with glycerine, which prevents the condensation of breath upon its surface, does away with the necessity of warming, and, besides, has the advantage that the mirror may be kept in position as long as the patient will allow, the view remaining as clear at the end as it is at the commencement of its introduction. I am, Sir, yours faithfully,

Bicester, March 2nd, 1885. EDWARD COTTERELL.

Inquirens.—The simplest way is to send a visiting card with the old address marked out and the new one inserted. It should be sent under cover, and, of course, only to actual patients.

W. B. B. will find instances of the kind in the work of Cornil and Ranvier.

"THE ADMISSION OF PATIENTS SUFFERING FROM FITS TO ASYLUMS FOR IDIOTS."

To the Editor of THE LANCET.

SIR,—With reference to Dr. Cobbold's letter in your issue of the 28th ult. I beg to say that, of course, the proportion of epileptic patients would vary considerably at different times. However, as I wrote from memory, and my only object was to correct what appeared to me to be a misapprehension on your part, I am willing to substitute the term "a large number" for "majority."—I am, Sir, yours faithfully,

Brentwood, March 2nd, 1885. J. R. WHITE.

Dr. James Gairdner.—We regret we cannot comply with our correspondent's request.

Gulstonian Lectures
ON
MALIGNANT ENDOCARDITIS.

Delivered at the Royal College of Physicians.

BY WILLIAM OSLER, M.D.,
PROFESSOR OF CLINICAL MEDICINE AT THE UNIVERSITY OF PENNSYLVANIA, PHILADELPHIA.

LECTURE II.

MR. PRESIDENT AND GENTLEMEN,—In considering the symptoms of endocarditis, it is important to bear in mind the manifold conditions under which the disease may develop. A limited number of cases may be grouped together as forming a primary, substantive disease; but in the great majority the affection is either an associated pathological state, or is of the nature of a secondary malady arising in the course of some other disease. In the primary cases individuals in perfect health may be attacked, or more frequently the disease affects those with chronic valvular endocarditis with perfect or failing compensation. Where the affection occurs after an injury or in the puerperal state, the cardiac condition must be regarded as part of the general sepsis, and is of the same nature as the pyæmic foci and the inflammation of serous membranes. The existence of the endocarditis in these cases has no special influence, and the phenomena may be just as marked without it. When the endocarditis supervenes in the course of some particular disease, as rheumatism or pneumonia, it is usually a secondary process, though indeed it may be regarded as directly produced by the causes which have excited the original diseases. The different modes of onset, and the extraordinary diversity of symptoms which may arise, render it very difficult to present a satisfactory clinical picture. The general symptoms are those of a febrile affection of variable intensity, which may be ushered in, like any acute fever, with rigors, pain in the back, vomiting, headache, &c. Arising in the course of some other disease, there may be simply an intensification of the fever or a change in its features. The pyrexia is constant, but variable in type and intensity, and more likely than any other symptom to lead to misinterpretation. Prostration of strength, delirium, sweating, and other signs of severe constitutional disturbance are usually present. Cardiac symptoms may be marked from the outset; pain, palpitation, sense of distress, and murmur; in many instances there has been old valvular disease, but in a considerable number of cases the heart symptoms remain in the background, hidden by the general condition and giving no indication; or they may be so slight that they are not even detected on special examination. The embolic processes give a special prominence to local symptoms, which may divert attention from the general malady. Thus delirium, coma, or paralysis may arise from implication of the brain or its membranes; pain in the side and local peritonitis from involvement of the spleen; bloody urine and pain in the back from affection of the kidneys; loss of vision from retinal hæmorrhage; and suppression in various organs or gangrene from the distribution of emboli.

So diverse are the features of malignant endocarditis, that a consideration of the symptoms is greatly facilitated by arranging the cases in groups, according as they display special characters. Dr. Kirkes, in 1852, called the attention of the profession to the occurrence of a typhoid-like condition in acute endocarditis, and he subsequently pointed out the fact that inflammation of the valves might lead to pyæmia. The investigations of Charcot and Vulpian,[1] of Virchow,[2] of Jaccoud,[3] and others, gradually led to the recognition of these two great types of the disease. Of late, still further separation has been made of the cases with features closely resembling ague or intermittent, and also of cases in which the cardiac symptoms are most prominent, and I shall call attention to certain cases in which the symptoms are those of an acute affection of the cerebro-spinal system.

First let me direct your attention for a few moments to those cases in which the endocarditis is merely a part of a septic or pyæmic state, the result of an external wound, a puerperal process, or an acute necrosis. Somewhat over 18 per cent. of the cases I have analysed were of this nature, the majority of them occurring in connexion with puerperal fever—11 per cent.,—the others in association with various wounds and injuries, or acute necrosis of bone. The puerperal cases appear most frequent after abortions, and the first symptoms usually develop within a week or ten days of delivery, beginning with rigors and fever, and running a course not essentially different from ordinary puerperal septicæmia or pyæmia without endocardial complication. Sometimes the onset of the symptoms may be much delayed, and the patient up and about her duties when the attack comes on. Usually, there is local inflammation of the uterus or ligaments; membranous diphtheritic endometritis and phlebitis are common. Occasionally there may be no special affection of the generative organs, as in a very severe case reported by Dr. Moxon,[4] in which there was extensive endocarditis of the right heart, and sloughing patches in the lungs. The woman had been delivered within the month, and the uterus appeared in a normal state for the period. The endocardial lesions are not necessarily ulcerative, but may be vegetative, and occasionally suppurative. It is very evident from the records that valves with sclerotic changes are most often affected. The visceral lesions are always suppurative, but do not appear to be more numerous than in cases of puerperal sepsis without endocarditis. The heart symptoms may be completely masked by the general condition, and the attention may be directed to them only by the occurrence of embolism. In this connexion it may be remarked that malignant endocarditis may attack pregnant women, and run a rapid course leading to abortion. In two cases of this kind, Litten[5] found no differences in the clinical features or anatomical condition as regards valves and metastases. In other instances, there may be the rigors, sweats, and irregular fever, leading to abortion, without the occurrence of any suppurative foci, as in a case reported by Guyot.[6] Dr. Trueman of Maccan, New Brunswick, has also sent me notes of a case which developed during pregnancy.

The cases of ulcerative endocarditis in traumatic and operative septicæmia are of a similar nature, but do not appear to occur so frequently as in the puerperal condition. Many of the cases occur after very slight injuries, as paring a hangnail or a corn, a sloughing pile, or the passage of a sound through a stricture. There are usually suppurative infarcts in the lungs; and even with extensive ulcerative changes in the left heart, the pyæmic foci may be all in connexion with the venous system and right heart. This was well illustrated in the case of a man aged twenty-five, who was admitted to the Montreal General Hospital, May 31st, with a wound of the radial artery. Phlebitis followed, and cellulitis of the arm, rigors, septic pneumonia, thrombosis of the femoral vein, and symptoms of pyæmia. At the necropsy, there were numerous foci in the lungs, and a suppurating thrombus in the femoral vein. The mitral valve presented on the ventricular face of the anterior segment a patch the size of a sixpence, swollen and greyish-white in colour, and opposite to it on the auricular face was an ulcer large enough to contain a small pea. There was another also on the wall of the left auricle. There were no infarcts in the arterial system. In these cases of puerperal and traumatic septicæmia, the right heart is more frequently affected than in any other group of cases. Thus, of the thirty-seven cases of this kind, there were thirteen in which the tricuspid or pulmonary valves were involved.

In acute necrosis of bone or acute osteo-myelitis, a secondary endocarditis may develop, and in some instances the clinical features may strongly resemble malignant endocarditis, as was well illustrated in the case of a lad aged ten, who died after an illness of less than a week's duration, characterised by high fever, rigors, sweats, &c. No local trouble was complained of, and at the post-mortem examination there was ulcerative endocarditis of the right side, and a purulent focus in the septum, and it was only after most careful search that the primary trouble was found in a small spot of acute necrosis of the tibia. These forms do not strictly come within the province of the physician, but they must be taken into account in any description of malignant endocarditis. The source of the poison is very

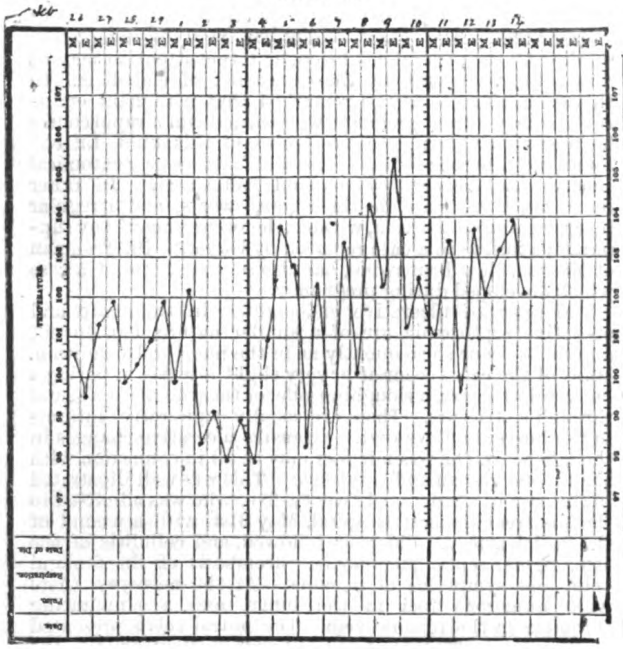
evident in the external wound; the metritis, &c., and the lesions are chiefly in the territory of the venous system and right heart.

In the pyæmic group of cases the clinical features are of a decided pyæmic type, and here the source of infection is at the heart, and the metastatic lesions are chiefly in the territory of the arterial system, rendering very applicable the name of arterial pyæmia given by Dr. Wilks to this class of cases. We may recognise two types of the pyæmic form: first, the cases in which the symptoms resemble closely those of ordinary pyæmia, with rigors at intervals, sweats, and other signs of septic infection; and, secondly, an important group, in which intermittent pyrexia is a striking feature, occurring in regular paroxysms like ague, with cold, hot, and sweating stages. These forms may develop as primary independent affections, or come on in the course of rheumatic fever, pneumonia, &c. In our Montreal cases they have not been so marked as the typhoid type. The following case, with illustrative chart, is a fair example of pyæmic symptoms due to endocarditis developing in the course of pneumonia.

M. W——, aged forty-three, a well built man, was admitted under Dr. Ross on February 26th, 1880. He served his time in the army; has had syphilis, and has quite recently had syphilitic ulcers; he has also been a hard drinker. In October, 1879, he was in hospital with pneumonia, and had

CHART 1.



severe cerebral symptoms. On February 23rd he had a severe rigor, followed by fever, cough, and pain in the side. On admission on the 26th there were signs of consolidation at the left base. On the 28th he was delirious. On March 1st the crisis seemed to take place; the temperature fell to 98°, remained low for three days, and he seemed to be doing very well. At 1 P.M. on the 4th he had a severe chill, with vomiting, followed by sweating. On the 5th he was delirious; had another severe chill at 2 P.M., in which the temperature rose to nearly 104°. Had five stools; no indications pointing to the heart. On the 6th the morning temperature was normal, the patient very prostrate, perspiration profuse, and there was low wandering delirium. From the 6th to the 9th the temperature rose a degree each evening, reaching 105·3°, its highest point. Pulse over 120 and feeble. From this time until the 14th he gradually sank, remaining unconscious. The lung symptoms did not extend, but rather improved. The post-mortem examination revealed extensive ulcerative vegetations on the aortic valves, purulent meningitis, and resolving pneumonia of the left base.

The attack may be ushered in with a single rigor, or more often a series of chills; and from the outset they may constitute a marked feature; and, with the sweating, prostration, and diarrhœa, give a septic character to the case. A light jaundice may develop, and still further intensify the resemblance. Sometimes the case may run on for a couple of weeks with marked typhoid symptoms, and then pyæmic features develop—rigors, sweats, &c.

But by far the most remarkable cases of the pyæmic group are those which present a marked intermittent type of pyrexia, simulating a quotidian or tertian ague. They may occur without any signs or indications of heart disease, or the symptoms may develop in individuals the subjects of chronic valvulitis. The cases are not nearly so frequent as those of the typhoid type; but they have been specially studied by Drs. Wilks, Bristowe, and Coupland in this country, Lancereaux in France, Leyden and others in Germany. The paroxysms may have the absolutely typical features of intermittent; the chills, hot stage, and sweating succeeding each other with regularity; and in the intervals there may be an entire absence of the fever. The quotidian type is the most common; the tertian has occasionally been described; and in rare instances two paroxysms have recurred within the twenty-four hours. The cases may be much prolonged, even for three or four months. One of the first references I find to cases of this kind is in a foot-note to one of Dr. Ormerod's Gulstonian Lectures,[7] in which a case of Dr. Bond of Cambridge is narrated—an instance of chronic valvular disease, with intermittent fever and diarrhœa, two paroxysms occurring in the day. The case lasted four months. In a remarkable case (Dr. Ray) described by Dr. Wilks,[8] during a six or seven weeks' illness, rigors recurred with such regularity that a tertian ague was suspected for a time, although the patient was known to be the subject of heart disease. In some instances the existence of ague previously has rendered the condition much more puzzling. In several of Lancereaux's cases[9] the patients had had intermittent fever a short time before; so also with one of Leyden's cases.[10] But the most extraordinary case of the kind is recorded by Dr. Bristowe.[11] A patient had ague in October, chills once or twice a day; ill for six weeks; and, after an interval of two or three weeks, they recurred in the second week of December, and continued until December 23rd. She was well for a few days, and then the attacks recurred after sleeping in a cold bed, and persisted until her admission to hospital on February 12th. For the four weeks previous to entrance, the attacks came every twelve hours regularly. A murmur was noticed; but the history of ague was so clear, and the attacks so characteristic, that a suspicion of malignant endocarditis was not at first entertained. It was only after the failure of quinine and a variation in the character of the paroxysms that a diagnosis was reached. In Dr. Coupland's cases[12] the intermittent pyrexia was also well marked. In none of our Montreal cases was the aguish type very pronounced, though in one or two cases there were regularly recurring paroxysms of chills, fever, and sweating; but the conditions under which the attacks developed rendered the clinical features more like ordinary pyæmia. The majority of these cases appear to arise independently of other affections, and occur among what I have referred to as the primary class of cases, though, as already mentioned, some develop in chronic valvular disease, and others appear associated in some way with ague.

The typhoid type is by far the most common, and the majority of the cases present features which come under this heading. The disease may set in with a single rigor or a series of chills, most frequently the former, often a period of malaise or ill health has preceded the attack, and in very many instances the symptoms develop in the course of some fever. The characters of this form are irregular temperature, early prostration, and involvement of the nervous system, delirium, somnolence, and coma, dry tongue, relaxed bowels, sweats, petechial and other rashes, and occasionally parotitis. Perhaps the majority of cases are mistaken for typhoid, as the heart symptoms may never be prominent, or even when sought for not found. The following cases illustrate the chief features of this form.

Ann O——, aged forty-six, a large well-nourished woman, was admitted under Dr. Wilkins on June 5th, 1881. She had been a healthy woman. Dr. Blackader saw her on the 2nd, when she complained of severe pains in the back, loins, and hips, which were relieved by poultices. Pulse rapid, tongue furred, no diarrhœa. When admitted she was supposed to be

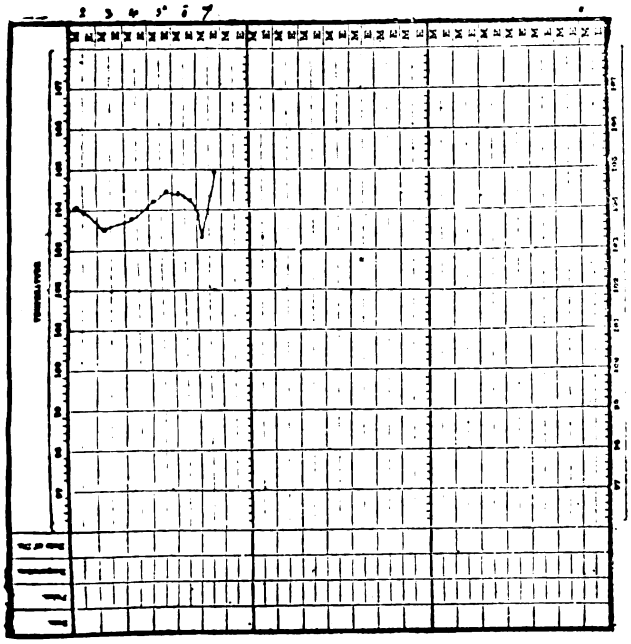
suffering from typhoid fever. No trustworthy history, family or personal, could be obtained, but she had been out of sorts for four or five days previous to the onset of the attack. On admission, temperature 104°; pulse 110; respiration 32; no eruption; lungs normal; no heart murmur; no albumen in urine. On the 6th she passed a restless night; temperature 104°; pulse 120, dicrotic; abdomen distended; two stools. Passed eighteen ounces of urine, slightly bloody, which may have been from the menses, which began to-day. On the 7th the morning temperature was 103·2°; pulse weak, 120; respiration 54, shallow; loud sonorous râles over chest; bowels and bladder emptied involuntarily; stools frequent, high coloured; patient cannot be roused. The legs and general surface seem tender, which causes her to cry out when moved. Urine drawn off by catheter contains much blood, 50 per cent. by volume of albumen, and many granular casts. Pupils unequal; head drawn

CHART 2.



to the right. Some rigidity of the muscles of the arms, most marked on the left; increasing coma, and death at 3.30 P.M. on the 7th, the sixth day of her serious illness. At necropsy, no hypertrophy of heart; mitral valves a trifle thick, with small superficial losses of substance of both curtains. Aortic valves normal; infarcts in spleen. Numerous small hæmorrhagic emboli in kidneys and throughout the intestines. Six or eight suppurating infarcts in brain, chiefly near longitudinal fissure and on median surfaces. The case is a good example of the primary malignant endocarditis occurring in a healthy individual, and running a rapid course, with symptoms of a typhoid character. The diarrhœa was not profuse, though the intestinal lesions were well marked.

In the following instance, occurring in connexion with pneumonia, the profuse diarrhœa and severe nervous prostration were very suggestive of typhoid fever:—

J. H——, aged forty, drayman, a large well-built man, was admitted on May 13th with pneumonia. He had been a pretty healthy man, though he had had two previous attacks of inflammation of the lungs. He had been in the habit of taking stimulants. Present illness began on the 11th with the usual signs of pneumonia, for which he consulted Dr. Blackader. On admission he was delirious; temperature 105°; respiration 60; pulse 110; consolidation of lower two-thirds of right lung, with the usual physical signs of hepatisation. On the sixth day the delirium was less marked and the temperature had fallen to 101·5°. On the ninth day the fever was 103°, and the condition of lung remained about the same. On the twelve day I saw him with Dr. Molson. The dulness appeared to be diminishing at the right base; I could detect no murmur at either apex or base of the heart. The condition of the patient resembled closely other cases of pneumonia in which ulcerative endocarditis had developed, and I suggested the possibility in this instance. Tongue was furred, no abdominal distension; no spots; diarrhœa had come on in the past few days; stools thin, yellowish in colour. Patient was dull and heavy, not actively delirious. On the eighteenth day the temperature rose to 104·5°, and for the next four days kept about that height. On the twentieth day the diarrhœa, which had been checked, began again. On the twenty-third day (June 1st) the temperature was 104·5°; pulse 96; respiration 30. Dulness diminished at the right base, still evident in scapular region at lower part; moist râles over the back of lung; rhonchi, sibilant and sonorous, heard in front. A single large dose (thirty grains) of quinine, at 4 P.M., did not affect the temperature, which at 10 A.M. was 105·5°. On the twenty-sixth day he was much the same, temperature has kept about 104°; two or three loose stools each day, low delirium, restless at night. For the next three days the fever was not quite so high, the diarrhœa ceased, and he became somewhat rational. Still deficient resonance in the right lung behind. Respiration kept about 30, and pulse under 100. On the night of June 8th the patient was very restless, and required constant watching; temperature 105°; pulse more rapid, 130. On the 10th he was more drowsy, pulse feeble, 140; large moist râles heard over both lungs. In the evening he had a rigor; temperature rose to 105°, and death took place on the morning of the 11th, just a month from the onset of the disease. Petechiæ had appeared on the skin during the last few days of his life.

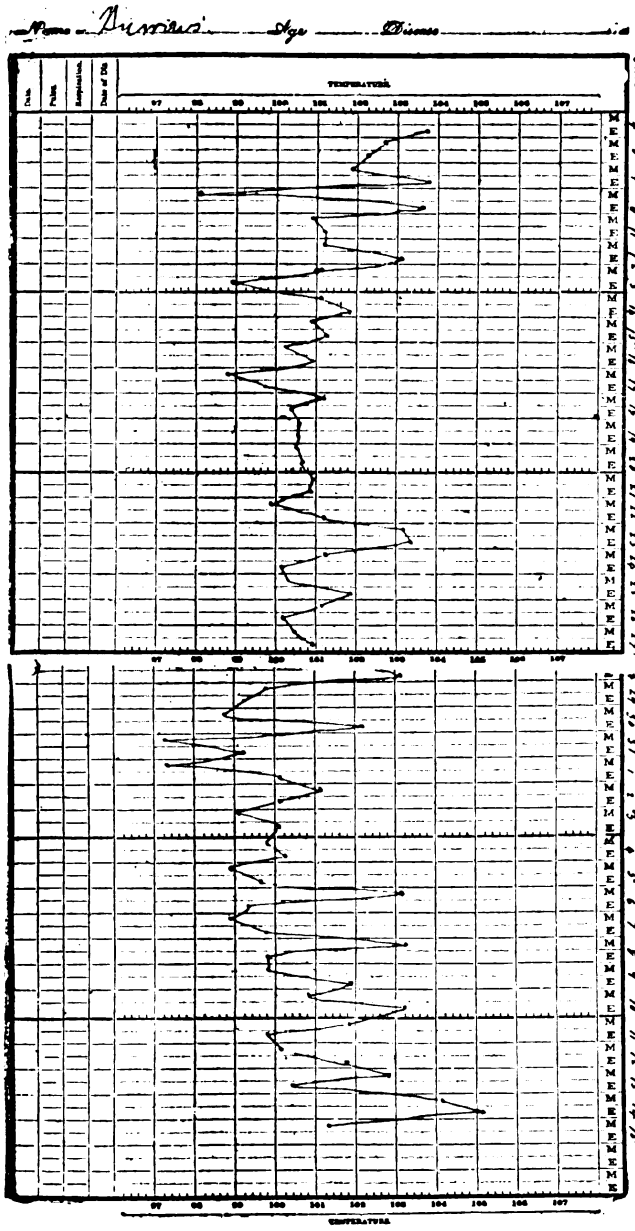
Necropsy, five hours after death.—Body not emaciated, petechiæ on skin in various regions. In abdomen, patches of dark extravasation noticed upon coils of intestines, both large and small. In thorax, right lung intimately adherent. Heart: Subpericardial ecchymoses. Numerous petechial spots beneath the lining membrane of the cavities; some of them are as large as split peas, and on section present a greyish centre, as if they were small infarcts. The mitral segments were natural-looking on the ventricular surface, but on separating the edges large masses of vegetations were seen blocking the orifice. They were attached to the auricular faces, about two to three millimetres from the edge; that in the anterior segment was about two centimetres in extent, and projected twelve millimetres. It was roughened on the surface. The growth on the posterior segment was smaller, irregularly divided into two bulbous portions, the surfaces of which were smooth. The aortic orifice was blocked with a clot, and the right anterior valve presented an enormous mass of vegetation, which occupied the entire curtain, except the edge, and infiltrated the whole thickness, appearing in the sinus as small nodular masses. Two perforations existed between the outgrowths, each about the size of a crowquill. The posterior segment presented a flattened vegetation, which encrusted the centre of the valve, and extended up to the corpus Arantii. All of these masses had the same appearance; colour greyish-yellow, except where coated with adherent blood-clot; those on the anterior mitral segment and on the posterior aortic were roughened, and the granular substance exposed; three others presented smooth surfaces, as if covered by a thin membrane. They were soft, on section granular, uniform throughout, and the consistence of pith. Coronary arteries free. Lungs: Right closely bound to chest wall by old fibrous adhesions. Posterior part of organ heavy, but crepitant, except at upper part of lower lobe, which, with a band about five centimetres in breadth of the lower part of the upper, and part of the middle lobes, were firm, airless, and granular on section. Colour liver-red, interspersed with small opaque areas, the plugs in the air-cells undergoing fatty change. Left lung healthy. Spleen weighed 185 grammes, pulp soft. No infarctions. Kidneys of average size; numerous small infarcts, chiefly in cortex; small hæmorrhagic areas with grey centres. Intestines: The deeply ecchymotic patches seen externally corresponded with small infarcts situated in the submucosa, and were surrounded by a zone of deeply hæmorrhagic tissue, above which the grey pale glandular layer could be distinctly seen. The infarct itself was about the size of a split pea, a little elevated, on section deep red or greyish red, not in any instance purulent, and surrounded by a zone of extravasation from one to three centimetres in diameter. They were most abundant in the ileum, about twenty in number. Peyer's glands not swollen. Liver pale, swollen, and soft. Brain: Vessels of pia mater full, parts at base normal. Thick purulent lymph beneath arachnoid, covering central part of fissures of Sylvius on both sides,

over both frontal lobes at anterior part, over the left intra-parietal fissure and on upper part of cerebellum, close to great transverse fissure. A good deal of serosity beneath the membranes. No infarcts in substance of brain.

In some instances, the clinical features are mixed; typhoid and pyæmic characters may alternate, as in the following case.

J. B——, aged thirty-eight, admitted Jan. 7th, 1880, has been a healthy man. Ten years ago he had a severe attack of pneumonia. On the night of Jan. 4th he felt uneasy, and did not rest well; got feverish, and in the morning had pain in the side and cough. No rigor. Symptoms continued and

CHART 3.



he came to hospital on the 7th. On admission the temperature was 103°; pulse 128; respiration 40. Signs of pneumonia in right lung, lower three-fourths. Characteristic expectoration. During the first week in hospital nervous symptoms appeared, he became delirious and passed urine and fæces in bed, tongue dry, and on the 9th and 10th there was troublesome vomiting. The temperature was irregular, ranging from 100° to 104°; the evening record was usually high, but twice it was lower than the morning. Pulse 120 to 148; respiration 32 to 50. During the second week the intensity of the symptoms abated; the temperature kept lower, not once reaching 101°. The nervous prostration continued with tremor of the whole body, and the discharges were passed involuntarily. Tongue very dry. A very disgusting fetor emanated from the body. He lay like a patient in the third week of severe typhoid fever; took food and stimulants well. On the 19th a painful swelling appeared in left the parotid region, and he began to have chills, and sweated a great deal each day. No objective indications of heart trouble. The lung cleared very much in the third week, but the prostration continued. During the fourth week the swelling of the parotid increased, and on Feb. 1st an abscess was opened in this region. On the 30th there were severe chills, with blueness of face and finger-tips. Much sweating, of a profuse drenching character. Became brighter after the abscess was opened, and the nervous symptoms were less marked. Temperature ranged from 98° to 100°, rising with the chills. In the fifth week he remained in this state, with but little change, occasional chills and profuse sweats, the picture being more like severe pyæmia. In the sixth week the prostration increased, and he lay in a heavy unconscious state. No chills, but most profuse sweats. On Feb. 13th and 14th the temperature rose very high, reaching 105°, and death took place on the 15th, after an illness of forty-two days. The necropsy revealed extensive mitral endocarditis, as the only special lesion. The base of the right lung was a little firmer than the left, but not granular on section. Only one infarct found, which was in the upper part of the spleen. Intestines healthy; no meningitis. The parotid abscess had almost healed.

Cardiac Group.—Under this heading may be arranged, as suggested by Dr. Bramwell,[13] those cases in which patients, the subjects of chronic valve disease, are attacked with febrile symptoms and evidences of a recent endocarditis engrafted upon the old process. I have already remarked on the great frequency with which ulcerative changes are found in connexion with sclerotic endocarditis. Many of such cases present features of the pyæmic, typhoid, or cerebral types, and may be of the most acute character; but in others the process appears much less intense, and the cause more chronic. In a considerable series of cases the history is somewhat as follows: the patient has, say, aortic valve disease, and is under treatment for failing compensation, when he begins to have slight irregular fever, an evening exacerbation of two or three degrees, some increase in cardiac pain, and a sense of restlessness and distress. Embolic phenomena may develop; a sudden hemiplegia; pain in region of spleen, and signs of enlargement of the organ; or there is pain in the back, with bloody urine. In other instances peripheral embolism may take place, with gangrene of foot or hand. There may be hebetude or low delirium. Instances such as these are extremely common; and while in some the process may be very intense, in others it is essentially chronic, and may last for weeks and months, so that the term malignant seems not at all applicable to them; still in a large series of cases, all gradations can be seen between the most severe and the milder forms. Dr. Green[14] referred to a case which lasted six months, and to another in which, during eighteen months, there were attacks of irregular fever. I have known the febrile symptoms subside for weeks, to recur again with increased severity, and there are cases which render it probable that the process may subside entirely. The ulcerative destruction in these cases may be most extensive, and I have seen the aortic ring with scarcely a trace of valve substance left. The process in the chronic cases is also mycotic, and it is to be carefully distinguished from the atheromatous changes. In very many instances there is no history of rheumatic fever or other constitutional disorder, but the endocarditis appears to attack the sclerotic valves as a primary process, and a very considerable number of the most typical cases are of this kind. A good example was the following case, in which the disease attacked deformed and hardened valves, and the clinical symptoms were prolonged for nearly three months.

H. M——, aged thirty-eight, was admitted on Sept. 8th, under Dr. Ross. Good family and personal history; has always enjoyed excellent health. A month ago had chilly feelings, fever, and sweating, with vomiting. Kept about until ten days before admission, when he took to bed, with pains at heart and fever. On admission, marked aortic incompetency; temperature 100°; seemed dull and heavy.

[13] Diseases of the Heart. [14] THE LANCET, vol. i., 1884.

On the 15th there was iliac tenderness and some diarrhœa. For the next two weeks the patient remained in the same state, the temperature rising at times to 103°. During the first week of October the prostration increased, and there was slight delirium at night; temperature not higher than 102°. On the 14th there was an eruption of petechiæ. From this time the temperature kept lower—100° to 101°,—the delirium and prostration increased, and death took place on the 23rd. Two of the aortic cusps had fused, and there were old sclerotic changes; there were recent soft greyish vegetations; spleen presented six or eight infarcts, one suppurative.

These are the cases of ulcerative endocarditis which present fewest difficulties in diagnosis. The existence of the chronic heart disease excites attention; and even if compensation has previously been perfect, the ulcerative process may be the very cause of disturbing the balance and producing marked symptoms. In my experience the existence of fever is invariable when the ulcerative processes are due to micrococci, whereas most extensive destructive changes may occur in atheromatous disease without any elevation of temperature. It may be possible that the granular detritus discharged from atheromatous foci on the valves, or on the aorta, may have irritating properties, yet in two instances I have met with most extensive atheromatous ulcers on valves and aorta, from which large quantities of material must have been discharged, and the patients were not febrile. Dr. Sansom,[15] however, has referred to a case of ulcerative endocarditis in which there was no elevation of temperature throughout.

The Cerebral Group.—A considerable number of cases of malignant endocarditis come under observation, perhaps, in hospital practice, for the first time, with symptoms of cerebral, or even cerebro-spinal, trouble. In three of the Montreal cases the patients were brought to hospital unconscious, and presented the appearance of profound cerebral affection. One of the first cases I saw was of this kind. The patient, a woman aged twenty-nine, was admitted on October 22nd in an unconscious state, and no history could be obtained. On the 24th she became partially conscious, and complained of great pain in the head and back of the neck. Symptoms of slight apex pneumonia were detected. Temperature up to 104°. On the 25th she passed urine and fæces involuntarily. There was strabismus of right eye, and commencing ulceration of left cornea. Death took place on the 26th. The symptoms were those of an acute meningitis. The post-mortem examination revealed apex pneumonia, a patch of endocarditis on mitral, and suppurative meningitis, involving chiefly the cortex. Another case, almost the counterpart, was admitted last year, under Dr. Molson, in an unconscious state, and died eighteen hours after admission, when the necropsy revealed apex pneumonia, extensive endocarditis, and suppurative meningitis. There may be early unconsciousness or delirium without any meningeal implication, as in a case of primary endocarditis admitted June 5th, 1881. The patient may be wildly delirious or unconscious at the first visit of the medical man, as in a case narrated by Eberth.[16] Very many of these cases die within two or three days of admission, and the question of diagnosis has usually to be suspended; indeed, in looking over the records of eleven instances in which these cerebral symptoms were early, they appear to run a more rapid course than other cases. In two remarkable cases there was cerebro-spinal meningitis. Hunolle[17] records a case of a lad who was admitted with symptoms at first like those of typhoid, and then of a marked cerebro-spinal character. There was also a pulmonary affection and endocarditis. He lived five days. At the necropsy, there was suppurative meningitis of brain and cord, pneumonia of one lung, and extensive ulcerative endocarditis, with old sclerotic changes. A still more remarkable case is reported by Heinemann.[18] A boy aged fourteen was admitted on Nov. 19th. For the previous two days he had suffered from pains in the back and legs, chills, fever, loss of appetite, vomiting, and constipation; was rational on admission; tongue coated; temperature 105·2°; condition of heart and lungs negative.—20th: Morning temperature 103·4°; evening, 105·6°. Fæces and urine passed involuntarily.—21st: A purpuric eruption noticed on the chest, then on face, and afterwards on legs and arms. Temperature 104·8°; pulse very feeble; delirium; hyperæsthesia along the spine; no opisthotonos; pericarditis suspected. At 11 P.M. of this day, a second crop of purpuric spots came out; temperature 106°; convulsive movements.—22nd, 3 A.M., second convulsive seizure, and death. At the necropsy there was purulent exudation on brain, and the meninges of cord were congested, opaque, and inflamed. Congestion of lower lobe of lungs. Recent vegetations on mitral, and near apex on anterior wall of the left ventricle, a small cavity, indicative of probable abscess and destruction of tissue. Purulent serum in pericardium; kidneys presented embolic abscesses.

Certain clinical features may be specially referred to in a few words. The fever, as will have been gathered from the previous statements, is of a very variable character. Irregularity is the prominent feature; periods of low may alternate with periods of high temperature, or a remittent may become an intermittent. A remittent type is most frequently met with, but the remissions do not occur with any regularity. Occasionally there may be a continuous high fever, the thermometer not registering below 103° for a week at a time. The pyæmic and aguish types have been sufficiently noted. The occurrence of a rash has been described by many observers, and in some instances has led to errors of diagnosis. The most common form is the hæmorrhagic, in the form of small petechiæ, distributed over the trunk, particularly the abdomen, less often on the face and extremities. They may be most abundant over the whole body, and at times are large and present small white centres. When severe, nervous symptoms are also present, the resemblance of the cases to cerebro-spinal meningitis, or typhus, may be very close. In one instance the case was thought to be hæmorrhagic variola.[19] An erythematous rash has also been observed. In a case of Dr. Cayley's[20] there was a mottled red rash on the skin. Colson[21] describes a case in which the rash was erythematous, and in spots distinctly papular. The mental symptoms may be of a very varied character. By far the most frequent conditions are low delirium and dull, semi-conscious, apathetic state. There may be at the outset active delirium, or even maniacal outbursts. In a case of Dr. Habershon's[22] there was a condition described as mental eccentricity. When there is extensive meningitis there is usually a condition of deep coma. Sweating is a very frequent symptom, and is worthy of special notice, from the peculiarly drenching character, which is, as Dr. Henry Thompson remarks,[23] second only to ague, and usually far beyond the average mark of phthisis or pyæmia. The diarrhœa is not necessarily dependent on any recognisable lesion, and may not be very marked, even when the infarcts on the mucosa are most abundant. As noted in several of the cases, it may be profuse, and still further add to the resemblance which some of the cases bear to typhoid fever. Jaundice may be present, but appears to be a rare symptom. Cases, some of which were mistaken for acute yellow atrophy, are reported by Schnitzler,[24] Gubler,[25] Luys,[26] and Mattice and Chalvet.[27] The heart symptoms may early attract attention, from the complaints of pain and palpitation; but, as a rule, they are latent, and unless looked for are likely to be overlooked. In those cases with chronic valve disease there is usually no difficulty, but where the affection sets in with marked constitutional symptoms, the local trouble is very apt not to attract attention. Even on examination there may be no murmur present, with extensive vegetations, or it may be variable. There are many instances on record, by careful observers, in which the examination of the heart was negative.

The course of the disease presents many variations, well illustrated by the records I have given; very acute cases may run their course within the week, as in the patient Ann O——, already referred to, while in others the duration may be even two or three months. Except in certain cases in which the patients are the subjects of chronic valvulitis, the course is rarely prolonged beyond four or five weeks. Some of the pyæmic group, particularly those with intermittent pyrexia, appear very prolonged, even two or three months. The most rapidly fatal case is described by Eberth,[28] in which a man, who had enjoyed previous good health, was attacked on the evening of the 25th, with rigors, followed by high fever and rapid unconsciousness. The temperature that night, when seen by a physician, was

41° C., and the case seemed like one of typhus with meningitis. On the 27th he was removed to the hospital, where he died at 5 P.M. Temperature was 42·4 C. There were extensive ulcers in aortic valves, and suppurative infarcts in the brain. The duration in this case was scarcely two days. In a considerable number of instances the disease terminates within a week or ten days.

Croonian Lectures

ON THE

HYGIENIC AND CLIMATIC TREATMENT OF CHRONIC PULMONARY PHTHISIS.

Delivered at the Royal College of Physicians,

BY HERMANN WEBER, M.D.,
PHYSICIAN TO THE GERMAN HOSPITAL.

LECTURE I.

Definition of Phthisis.—Infectiousness.—The Bacillus.—Differences in the liability of different Persons to Phthisis.—Acquired and Hereditary Predisposition.—Curability of Phthisis.—Circumstances influencing the Prognosis.—Deplorable Condition of the Consumptive Poor.—Preventive Treatment.

MR. PRESIDENT, FELLOWS, AND GENTLEMEN,—Drs. Wm. Ewart, J. E. Pollock, and Andrew have delivered before you in the course of the last few years lectures on important points in the etiology, pathology, and treatment of phthisis. I intend to confine myself as much as possible to the hygienic treatment in the widest sense, which includes the dietetic and climatic management. Graves said: "It is of great importance to know how to make a man phthisical, as by pursuing an opposite line of conduct we will be able to prevent it." In these words lies my excuse if I do not altogether avoid questions of etiology and pathology.

While the lectures of my predecessors to whom I have just alluded were full of scientific research, mine claim only a humbler place; but if I were only able to put the matter as I see it before you and the profession in general with sufficient clearness and force, I should hope to be fortunate enough to contribute a small share towards the development of a more energetic and somewhat more successful prophylaxis and treatment of phthisis, especially in the poorer, but also in the richer, classes. As the word "phthisis" had such different meanings at different times, and at the same time in the minds of different men, I must state what I mean by pulmonary phthisis—viz., a chronic disease of the lungs, with consolidation, beginning almost always at the apex, having a tendency to caseation, softening, and the formation of cavities, or of fibrous changes—all these changes may occur in the same individual at the same time in different parts of the lungs, or may follow one another at different periods of the disease. These changes are endowed with infective qualities, and have a disposition to spread to the adjacent parts, and to become also disseminated over distant parts. They are mostly found associated with the tubercle bacillus discovered by Koch, a point to which we shall presently return; and they are intimately connected with, we might say engrafted on, a state of malnutrition of the whole organism, and especially the cells and the tissue of the lungs. I claim no originality for this definition, which is not exhaustive, and which I have given only for the purposes of these lectures. It is derived principally from the remarks made by Drs. Green, Wilson Fox, and others during the discussion at the Royal Medical and Chirurgical Society on Dr. Percy Kidd's paper on the "Distribution of Tubercle Bacilli in the Lesions of Phthisis." I exclude the lung diseases often called phthisis, which are caused by mechanical irritation through inhalation of inorganic or simple organic dust, the different forms of bronchiectasis, chronic bronchitis, or emphysema and heart disease, chronic changes resulting from pressure on the bronchus, the diseases of hydatid origin, cirrhosis, empyema, and syphilitic changes of the lungs.

With regard to the infective power of the changes in the lung of phthisical subjects, they have been surmised long ago, even before the history of inoculation, which dates back at least as far as 1843, when Klencke made some experiments which were almost forgotten when Villemin published his famous researches. The late William Budd, you remember, was perfectly convinced of the infectiousness of phthisis. On more than one occasion, when discussing the subject with him, he expressed his astonishment that the view of the infectiousness was not universally credited. Mr. Wm. Thompson of Melbourne, amongst others, has constantly asserted his belief in the communicability of phthisis.

Possibly this view would not have been so generally accepted even now if the ideas of the profession with regard to zymotic diseases had not been gradually transformed by the researches of Pasteur, to whom the greatest praise is due, although he was preceded in some points by Schwann, that type of the modesty of genius, and had not the marvellous results obtained by Lister's disinfecting process acted as a stimulus to the germ theory in general. Pasteur's intelligent and never-resting industry paved the way for a number of other scientific observers and experimenters, as Davaine, Obermeier, Cohn, H. V. Carter, Cohnheim, Klebs, Wilson Fox, Burdon Sanderson, Baumgarten, Lister, Tyndall, Tommasi-Crudeli, Klein, and others; so that Koch's discovery of the tubercle bacillus came to us like a long-expected message.

Dr. Andrew especially dwelt on the importance of this discovery in his lectures on the Etiology of Phthisis, where he justly said that "not many discoveries of equal importance" have received such speedy and strong "confirmation as that of the tubercle bacillus." Mr. Watson Cheyne has given a full, clear, and confirming account, based on a visit to the Continent and many experiments performed by himself. The literature on the subject in this country, as also in France, Germany, Italy, and America, is already very large, and has received an important addition by the paper already mentioned by Dr. Percy Kidd, and the discussion which followed it. In spite of the large array of authors and papers, however, we cannot say that we know all about the bacillus, by which term I understand not only the developed little rod, but also its spores and the chemical poison which probably is originated by its development in the tissues in an analogous manner, as, according to the researches of Gaspard, Panum, Billroth, Burdon Sanderson, and others, a powerful chemical poison—sepsin—is developed in the process of septicæmia. We have no doubt that the bacillus is intimately associated with phthisis, but the exact relations appear to require still further elucidation. It is, for instance, not quite clear why the tubercle bacillus thrives in some persons and not in others, or why in some persons it thrives at one time and not at another.

It seems to be an acknowledged fact that some microorganisms do not grow in living tissues of a living animal. Klein states this with regard to the "septic and zymogenic organisms properly so called," and explains their occurrence in diseased tissues during the life of the subject by assuming that these tissues had become changed by inflammation or otherwise, so as to become practically dead before the organisms could grow in them. By analogy, the question arises whether the tubercle bacillus settles and grows in healthy living tissues of the body or only in pathologically altered tissues. We know that it thrives in the bodies of most warm-blooded animals when inoculated, but this does not prove that it will find a nidus in the healthy tissue when merely brought into contact with it by the surrounding air. The first point which we have to consider is that the air which we inhale perhaps does not so often contain the fully developed bacillus as it is supposed by many people, for this microbe does not thrive in the air at the usual temperature, but requires, according to Koch, a temperature approaching that of the human body. Its growth entirely ceases below about 82° F. and above 107°, and it thrives best at about 98° to 100°, while other pathogenic microbes have a much wider field; for instance, the anthrax bacillus, which grows luxuriantly between 67° and 74° and up to 110°. A further point against the spread of the tubercle bacillus out of the animal body is that it does not form spores in the air, while the anthrax bacillus does. Another peculiarity in the life of the former is that it grows slowly, that it requires as many days for its development as the anthrax bacillus requires hours. This circumstance seems to diminish our danger considerably, for we may presume that the bronchial mucous membrane, when healthy, materially assists the expelling act of expiration by its ciliary functions. We are,

however, less secure when by catarrhal or inflammatory conditions the mucous membrane of the bronchi, and especially of the smallest divisions, is deprived of its protecting surface, and when the respiratory acts are imperfectly performed, especially the expiration, thus allowing the stagnation of impure air in the alveolar spaces, and permitting the bacilli and their spores to develop under circumstances most favourable to them.

This leads me to another subject in the relation of the *bacillus* to phthisis, which appears not finally settled—viz., the chronic affections of the apex, which are usually regarded as incipient phthisis. Every one of us has seen numerous cases of this kind characterised by some degree of dulness, mucous rhonchus, and more or less pyrexia at one time or other. Many of these cases are followed, after a shorter or longer time, by an extension of the disease to other portions of the lung and fatal termination. Not a few cases, however, become arrested and retrogressive, and ultimately to all appearances cured. These apparent cures are not always permanent, but after intervals of from four to six months, or some years, a similar affection is started up again, either in the same or in the other apex, or in both, and may rise into fully developed phthisis, or be again arrested. In looking over my notes, I have found eleven cases in which the arrest or cure has now lasted from five to twenty years without a relapse, so that the cure may be regarded with some degree of assurance as permanent. What was the nature of these cases? Were they bacillary or non-bacillary? I cannot answer the question with any degree of certainty, as the bacillus was not known at that time, and only its constant absence in the sputa could have pointed with probability to the non-bacillary character of the affections. I am inclined to believe (1) that some of the apical affections which I have seen were non-bacillary, or, in other words, the result of chronic catarrh and inflammation without the presence and influence of bacilli; while the greater number were complicated by the presence of the parasite, and partly caused by the latter; (2) that non-bacillary cases are apt to become bacillary by the settling of the bacillus in the diseased cells and tissues; (3) that bacillary cases may, under favourable circumstances, become non-bacillary. The recent discussion already referred to at the Medical and Chirurgical Society has not cleared up the question. Dr. Wilson Fox in his philosophical remarks told us we ought not to be too quick in accepting all which the new views of the bacillary origin of phthisis required, considering that the pathology of tuberculosis had biennially, triennially, or quinquennially been swayed by histological dogmata. Dr. Green, on the other hand, seemed more thoroughly to accept Koch's discovery, as being in perfect harmony with our older views, and his (Dr. Green's) definition of phthisis. He questions the existence of pre-tubercular consolidation of the apex, which term may perhaps be understood as equivalent to non-bacillary consolidation, which I have used above. He appeared, however, not quite certain on this point. In some cases of disease of one apex, he said, where there was no evidence of softening and disintegration, it was difficult to say whether they were tubercular or not. I have been told that it is imprudent to discuss in our present state of transition the question of the treatment of phthisis. But I do not quite share this opinion. If we could hope that by further acquaintance with the nature and life of the bacillus we could at an early date discover a method of attenuation of the tubercle virus for inoculation, or means of destroying the bacillus and its spores, either in the air we breathe or in our tissues, or substances by which without injury to ourselves some slight alteration in the chemical constitution of our cells and tissues could be effected which would render the thriving of the bacillus impossible, I should certainly wait; but I do not think that we are justified in entertaining such hopes for the near future, although the discovery of some such means does not appear to me at all impossible. We are not so fortunate as surgeons with regard to keeping off the entrance of spores into wounds and sores. The ingenious respirators invented by Tyndall and Frankland are certainly not without practical value, but their use will, I fear, never be general; and when once the system is infected, we do not yet know of parasite-killing remedies which, in sufficient doses, would not injure the host together with the parasite. Even the surgeon, when once pyæmia or septicæmia is established, has hitherto found himself powerless to arrest the progress of the disease by means of antiseptic remedies administered internally. He even has great difficulty in disinfecting an external sore when complicated with sinuses. I well remember a conversation with Sir Joseph Lister on this subject, when he held out no hope that we might at an early date succeed in disinfecting an infected lung. The conversation I refer to occurred some years ago, but I have no reason to believe that Sir Joseph has altered his views since then. Although, however, we possess no direct means of destroying the parasite, we need not despair of doing good by placing persons under circumstances in which they are less liable to become infected, and when infected more able to limit the progress, and to effect a more or less perfect and more or less permanent cure. We know that the reputed cause of danger, the tubercle bacilli or their spores, exists in many localities, and yet, fortunately, the majority of people remain free from tubercles, and that some only become infected after some accident, some lowering influence, mental or physical, or some catarrhal inflammatory affection of the respiratory organs, or some febrile disease, as measles, or whooping-cough, or typhoid fever. There is reason for the inference that under such depressing influences the resisting power of the body, and especially of the lungs, becomes impaired, and that thus the pathogenic germs are more likely to find a nidus for their development. This diminished resistance thus produced constitutes the complex class of *acquired predisposition*, which may be transitory or permanent. Our duty is to prevent the occurrence of this predisposition, and when formed to remove it by improving the state of nutrition. And a further duty is to prevent, during the existence of this acquired predisposition, the risk of infection.

There is, besides, an equally large, if not larger, class of persons who have *hereditary predisposition* to phthisis. We must avoid entering on the exact nature of this heredity, whether it consists—as Professor Sée, in his very interesting work, "Phthisie Bacillaire des Poumons," argues—in direct transmission of the virus from parents to offspring, or whether only in the transmission of certain predisposing defects. But we shall, under the head of "prophylactic treatment," return to the consideration of the duties which the existence of heredity imposes on us.

Before I enter on these duties, I must say a few words about prognosis, and endeavour to meet the gloomy views which so many medical men still entertain. That anyone can hold the opinion that phthisis is incurable is almost incredible; as not only older medical authors, but many of the most experienced living men, have pronounced distinctly hopeful views. The words of Carswell should be sufficient. 'Pathological anatomy," he says, "has perhaps never afforded more conclusive evidence in proof of the curability of a disease than it has in that of tubercular phthisis." Every one of us has, I doubt not, often met with this proof in making post-mortem examinations of persons who had died of other diseases. The instructiveness of most of such cases, however, is greatly diminished by the fact that the conditions of the person at the time when the attack had occurred are unknown; as also the circumstances under which the cure had taken place. As a great interest is attached to cases whose history is known, I venture to give a short sketch of a case in which I had the opportunity of witnessing two separate attacks of phthisis, terminating in recovery, and finding the remains of the lesions by post-mortem examination seven years after the second recovery, when death had occurred from typhoid fever with perforation.

C. M——, aged twenty-one, with history of phthisis on the part of his father, came under observation in July, 1867, on account of hæmoptysis. He had previously had attacks of "bronchial catarrh," as he called it. There was dulness with crepitant rhonchus over the left apex down to the fourth rib, and also on the supra-spinal region. The right side was free. Moderate pyrexia; loss of flesh. With rest in bed, and on sofa, with open windows, light cold food and ergot of rye, the bleeding soon ceased. There was subsequent general improvement after removal to Weybridge, where he was ordered to be during the greater part of the day, in the pine forest of St. George's Hill, to take frequent meals, and cod-liver oil, with small doses of arsenic. He was then advised to spend ten or twelve months at Davos or St. Moritz, but as this advice was described by an authority who was separately consulted as due to my "cold-loving idiosyncrasy," C. M——, having found an engagement at Cape Town, went there. At that place he was disagreeably affected by the wind and dust, and was therefore sent to the high ground amongst the Boers, where he spent six months of the cool

season in several farms at elevations of between 4000 and 6000 feet, being constantly in the open air, with abundant exercise on horseback and walking. He entirely recovered, and was afterwards for some years at Cape Town and in the neighbourhood, in perfect health. In January, 1873, after a year's residence in Paris and London, he was again seized with hæmoptysis, the left apex had remained free, showing only slight dulness and flattening, and occasionally a dry crackle, but no moist rhonchi, while the right apex was in an analogous condition, as the left had been in 1867; under a similar treatment he again improved, and being a good sailor he went on board a sailing vessel to Valparaiso. On the voyage the cough almost subsided; but at Valparaiso, where he began office work, it became worse, and he was advised to carry out my previous suggestion to spend a year at Jauja in the Peruvian Andes, whence he returned to Valparaiso in perfect health. In 1878 I had the opportunity of examining C. M ——, when on a visit to Europe. The former flattening and dulness over the left apex had disappeared; the breathing was only somewhat harsh with prolonged expiration, but over the right apex there was slight dulness on percussion, some flattening, and harsh long expiration. He was able to bear any amount of fatigue, but no confinement to close rooms and office work. I did not see him again till he came in August, 1881, from Italy and France, with well-developed typhoid fever, of a moderate type, without any lung complication. He had almost recovered, when at the end of the fourth week of the disease he committed, against strict advice, the imprudence of eating a rather large quantity of grapes. Perforation of the lower part of the ileum took place within twenty-four hours, from a sore which had been in fair progress of healing, almost all the other patches being already healed. There were cretaceous patches in the apices of both lungs, and also in the lower lobe of the right lung, with the often described changes in the surrounding tissues. Whether these two attacks of phthisis were bacillary, and, if so, whether the encapsuled cretaceous and semi-cretaceous masses still contained bacilli and spores, are questions which naturally offer themselves. If the bacilli and their spores can retain their life for years in such encapsuled masses, then it is very possible, as has been suggested by others, that the fresh attacks of phthisis which occasionally occur after years of apparently perfect cure are in some cases due to self-infection from the escape of imperfectly shut up parasites. A case lately published by Dr. Neuwerk of Tübingen tends to show that bacilli may really exist in such old encapsuled masses. The main points of the case are these:—A ranger in a healthy district of Prussian Silesia, who served in the Franco-German war of 1870-71, in perfect health, and passed in 1875 a medical examination as a good life, suffered in 1877 during six months from cough, anæmia, emaciation, and a general feeling of illness; he recovered, however, while continuing his open air duties, and then remained well for several years, till cancer of the stomach developed itself, from which he died. The post-mortem examination disclosed in both apices, which were contracted and puckered, cretaceous masses of different consistence, and also caseous nodules, in one of the latter of which Dr. Neuwerk found well-developed bacilli after having searched in vain for a long time. He ascribed the phthisical changes in the lungs to the illness in 1877. Dr. Neuwerk's case and the one related by myself have this in common: that indubitable attacks of phthisis were cured by what may be called "open air treatment," and that death occurred not from phthisis, but from other diseases. These cases, if we had no other proof, would in themselves be sufficient to show that phthisis is sometimes cured, and I do not hesitate to assert that it is often cured.

There is nothing more baneful than the idea that phthisis is incurable. It shuts out all honest attempt to do everything possible, and bring every sacrifice to promote arrest and cure. I well remember from my student's time, when phthisis was considered almost incurable; how the name of the disease was withheld from patients; how depressed they became when they found it out; how they regarded themselves as doomed, and sometimes killed themselves by poison or debauchery. I remember also the joy amongst the younger medical generation and the public when a more hopeful view developed itself, and the readiness to submit to every sacrifice and to long expatriation with a fair chance of recovery. I will not mention the names of the living men who have worked in this direction, but I cannot help paying a tribute to the memory of Graves, Carswell, Archibald Smith, Addison, and Felix Niemeyer.

The portions of lung which are already destroyed before the treatment has commenced cannot be restored, but experience has shown to us that life, with a fair capacity for work and for enjoyment, can be maintained after a loss of a good part of the lungs, and that the remaining part, if sound, can be rendered capable of doing the ordinary life-work of both entire lungs, though it must always remain unfit to perform the extraordinary duties which can be occasionally demanded from the combined power of both lungs in perfect health. That even the pressure of a cavity does not preclude a cure more or less complete, all the best observers of England, and many of the Continent, have proved. The phenomena of cavities have been carefully studied by Dr. C. T. Williams, Dr. Douglas Powell, and especially by Dr. William Ewart, whose Gulstonian Lectures of 1882 contained the fullest account of the pathology of cavities I am acquainted with. In some cases the formation of a cavity, as Professor Jaccoud and others have pointed out, is even favourable, provided the infectious contents can be thoroughly evacuated, and a fibrous zone of demarcation be established between the cavity and the surrounding healthy tissue. The tendency to fibrous change in this, as in all other processes of phthisis, is one of the most powerful agencies towards prolongation of life, and in many cases towards arrest and cure of the disease.

(To be concluded.)

Clinical Lecture

ON

TWO CASES OF

INJURY FROM THE DYNAMITE EXPLOSION IN WESTMINSTER HALL.

Delivered at the Westminster Hospital, February 26th,

BY GEORGE COWELL, F.R.C.S.,

SENIOR SURGEON TO THE HOSPITAL.

GENTLEMEN,—There is no necessity for me to call to your recollection the series of dastardly outrages by means of various forms of dynamite which have occurred at intervals during the past two years. They appear only to have succeeded in arousing in the public mind a deep feeling of execration against the cowardly ruffians who have perpetrated them; for it is marvellous, and a matter for deep congratulation, that so few individuals have been injured. The injuries, too, have been slight as compared with the enormous power of the explosive, but they present certain peculiar features which I think are worthy of your careful consideration. The two cases that have recently been under treatment in Northumberland ward afford a good opportunity of studying the effects upon the human body of that "resource of civilisation," a clumsily used charge of dynamite.

We are well acquainted with the results of explosions from gunpowder and from mixtures of gases. With these materials a mass of flame is produced, and the most marked effect upon any individual that is not blown to pieces is a more or less severe burn of the surface. With dynamite explosions, on the contrary, as they have come before surgeons in the recent outrages on the Underground Railway, at the Junior Carlton Club, and still more recently in Westminster Hall, it would appear that an individual may be within a few feet of the exploding material and yet escape with certain characteristic injuries, which I propose to discuss with you to-day.

Now, your first question would probably be, How was it that these two policemen, who were brought into the hospital soon after the explosion in Westminster Hall and who were close to the exploding material, were not blown to pieces? I think that there are two reasons for their escape: first, the chief energy of the explosion, which with dynamite is mainly exercised downwards, was expended in excavating a deep hole in the pavement of the Hall, and then diffused upwards and laterally; and, secondly, the explosive was not sufficiently confined for the production of its full effect.

[After alluding to the process of blasting rocks, and showing how much more destructive the Westminster Hall explosion would probably have been if the case had exploded in the passage in which it was first placed, whence it was pluckily removed by Cole, the lecturer described the condition of the clothes of the two men on their admission, their coats having been burst through by the explosive force, one having had the brass letter **A** on his coat collar bent and twisted, and the other having had the leg of his trousers slit up nearly to the hip.]

The faces and hands of the men were blackened, and the hair and beard and clothes filled with a black material. The disturbed dust from the rafters of the old Hall was the main factor of this blackening process. Both men had several slight superficial wounds of exposed parts, probably produced by the earth and pulverised stone that were thrown in all directions by the excavating effect of the explosion. The blood from these superficial wounds and the black dust fully accounted for the hair being in places matted together with a black compound. The men were, of course, knocked down by the explosion, and when brought to the hospital were stunned and deaf, but not insensible. They were cold, too, from the shock that they had received, and it was not until they were recovering from this shock that it was found that neither of them recollected anything of the explosion or subsequent circumstances from the time that they saw the flash till they found themselves in bed in the accident ward of the hospital. Cox heard the explosion, but Cole tells us that he did not. Cole, who has been rewarded for his pluck on the occasion, was found to be suffering also from considerable difficulty of breathing and pain in the left side, and a careful examination at once revealed the fact that four of his ribs—viz., the sixth, seventh, eighth, and ninth—were fractured. There were no signs of contusion at the seat of fracture, or other than the slight superficial wounds above mentioned and a few slight bruises of the arms and legs, and it appears that the fractured ribs were not directly caused by the explosion. What happened would seem to be this. Cole was violently swung round by the explosive force exerted upon his body and clothes, and fell into the hole produced by the explosion. He is a slight man, but Cox, who is of much heavier build, was swung round in much the same way, and fell upon his colleague in the hole, by his weight and fall so compressing Cole's sternum and left costal cartilages that the four ribs mentioned were fractured near their angles. It is clear that the fractures were produced by pressure upon the sternum, from their position and from the fact that there has been no sign of injured pleura or lung, a complication which must have occurred if the fractures had been produced by direct violence. The marked rotatory movement would seem to be a peculiarity of dynamite explosions.

The symptoms of shock from which these men were suffering were of a peculiar kind. Cox's were out of proportion to his apparent injuries, and rapidly passed into a stage of excitement. He struck out in all directions, and was with difficulty restrained. He certainly demonstrated that he had no broken bones. This excitement lasted about an hour. Cole had no stage of excitement. He was weighted by his quadruple fracture. In both men the signs of shock passed off very slowly in the course of four days. Both had headache, Cox's being worse than Cole's and lasting over a week, and being more marked in the frontal and occipital region. The deafness was not equal in amount in the four ears. In both men there was much more deafness on the side turned towards the explosion—viz., Cole's left ear and Cox's right. The other two ears recovered their hearing in eight or nine days, but in Cox's right ear the deafness recovered very slowly, and had hardly disappeared at the end of the fourth week. Cole's left ear is still deaf. It recovered to a certain point, but I fear that all improvement has now ceased. Cox had a little bleeding from his right meatus, and was found to have a ruptured tympanum, but the other tympani were covered, and perhaps defended, by cerumen, and were not ruptured.

Now, Why was it that the effects of the shock were so prolonged in these cases? and why was it that the deafness and the malaise and slight stiffness of the skin and muscles of the side of the face were so much more marked on one side, and so persistent? I think it was because the explosive force which knocked the men down produced a more powerful effect upon one side than the other. The partial rotation of the body by means of the clothes and the fall were almost instantaneous, but the rush of expanding gas, carrying perhaps particles of dust, produced a blow which left a soreness and a cutaneous hyperæsthesia, although not a bruise. The degree and persistence of the nervous shock produced by this lateral blow were due not only to some amount of concussion of the brain, but I think that we must also recognise that a little of the shock and almost the whole of the deafness were due to a concussion of the auditory nerve and of the expansion of the auditory nerve which lines the cochlea and semicircular canals. The effect of concussion upon this delicate nerve expansion is somewhat similar to that produced in concussion of the retina, a complete suspension of its physiological functions. The severity of this concussion on the side turned towards the explosion fully accounts for the prolonged deafness on that side, and might be sufficient to account in some cases for a permanent condition of partial or complete deafness. The recovery in Cole's left ear has been so slow that I fear, as I have already said, some deafness will remain as a permanent result of the explosion. It has been stated that this nervous concussion is likely to be greater when the tympanum escapes, as the giving way of that membrane breaks to some extent the force of the concussion. It is possible also that the prolonged headache was due to the concussion and irritation of the auditory nerve. Dr. Brown-Séquard has shown that such irritation has the power of producing by reflex agencies convulsions, vertigo, and other symptoms of disturbed cephalic function.

These cases are instructive because they teach us, in estimating the causes of traumatic shock in cases of explosion, not to ignore the presence of nervous concussion, even though the signs of it are more or less obscured. They teach us, too, that the essential treatment of concussion, perfect physiological rest, should be maintained in these dynamite cases, as giving those who are injured the best chance of avoiding permanent deafness or those other changes which may result from even the slightest concussion of nerve structures when rest is neglected.

ONE HUNDRED AND ELEVEN CASES OF LITHOLAPAXY.

BY P. J. FREYER, M.A., M.D., M.CH.,
SURGEON, H.M.'S BENGAL ARMY; CIVIL SURGEON, BAREILLY, N.-W. PROVINCES.

(*Concluded from page 423.*)

CASE 54.—On Aug. 1st, 1883, a Hindoo male, aged fifty came to hospital with symptoms of stone, the most marked of which were sudden stoppage of the flow of urine and increased frequency of micturition. After a most careful exploration of the bladder by sounds of various kinds, including Sir Henry Thompson's, no calculus could be detected. I felt certain, however, from the symptoms that there was a small stone present, and determined to employ the aspirator for the purpose of diagnosis. I introduced a No. 14 catheter, and applied the aspirator. After going through the performance of pumping water into the bladder, and exhausting it once or twice, a distinct click was heard. The cannula was withdrawn, the lithotrite introduced, and the stone crushed. The fragments weighed eleven grains only. Next day the man was walking about quite well. In the above case a most careful search was made by sounds of various kinds, but no calculus could be detected till the aspirator was employed; when a distinct click was heard during the exhaustion of the water, due to the calculus being carried with force against the eye of the cannula by the outward stream. The sound of the fragments clicking against the cannula during aspiration in the operation of litholapaxy first suggested to me this mode of diagnosis, and I now always employ it when the symptoms of stone are present, and the sound fails to detect one. In this way I have detected several small calculi.

Not alone may the aspirator be usefully employed for diagnostic purposes, but by means of it a small calculus or number of small calculi may be removed entire without the necessity of having recourse to the lithotrite at all. Case 76 is a practical illustration of this. The patient, a warder in the Moradabad gaol, aged fifty, had been passing gravel for two or three years, when suddenly one day his urine

ceased to flow. He went to the hospital assistant, who passed a catheter and relieved the retention. Next day he had retention again, when he consulted me at my morning visit to the gaol. I sent him to the civil hospital, placed him under the influence of chloroform, and passed a No. 18 catheter at once with the greatest ease. The aspirator was then applied and the click of a stone heard. The calculus, which weighed only fifteen grains, passed into the apparatus, and was removed in this way without the use of the lithotrite. Next day the warder returned to his work quite well, having suffered no unpleasant symptoms. I had for some time previously contemplated the removal of a small calculus in this way by the aspirator alone; but this was the first opportunity I had of putting my idea to a practical test. Since then I have removed calculi in four or five instances in this manner without the aid of the lithotrite. For instance, in Case 81 I removed twenty-seven small hard uric-acid calculi, the whole weighing half a drachm, all passing through a No. 16 cannula into the receiver; and in Cases 98 and 109 small calculi were both diagnosed and removed by the aspirator alone.

During the process of aspiration, with each expansion of the indiarubber bulb, the fragments of calculi are carried against the eye of the cannula by the outward rush of water, and a clicking sound is thus produced, which, whilst it continues, indicates that some fragments remain in the bladder. There is, however, a peculiar sound sometimes produced, which I have not seen mentioned in any text-book or journal, and the occurrence of which the young litholapaxist should be acquainted with, as it is very likely to be confounded with the sound produced by a fragment. This "false sound," as it may be called, is produced by the mucous membrane of the bladder being sucked into the eye of the cannula during exhaustion of the water. It is most likely to occur towards the end of the operation, when all, or nearly all, the fragments have been exhausted, and especially when the bladder contains no surplus water, only that quantity which is pumped in and withdrawn during compression and expansion, respectively, of the bulb. It may, however, be produced at any time if, after compressing the bulb, the eye of the cannula be turned towards the sides or directed up against the fundus of the bladder, and then the bulb of the aspirator be allowed to expand. The sound itself, though difficult to describe, can never be mistaken when once recognised. The sensation communicated to the hand is of a fluttering jerky character, accompanied by a dull muffled sound as contrasted with the clear ringing click which the impact of fragments imparts to the instrument. On its occurrence the outward stream receives a sudden and complete check, whereas when a fragment obstructs the stream a portion of the water continues to flow. The sound does not recur if the cannula be partially withdrawn and raised towards the perpendicular position, so as to bring the eye close to the neck of the bladder, with the end of the cannula resting on the trigone; whereas a fragment will produce obstruction there as well as in any other position. On first practising litholapaxy I was deceived by this sound, and quite recently I have seen a brother officer of the British medical service, who performed his first litholapaxy operation in my presence, similarly deceived, I having forgotten to mention to him the possibility of its occurrence.

Towards the completion of the operation it will be found, as a rule, that the last particles of débris lie close to the neck of the bladder, just behind the prostate. This is due to the fact that the eye of the cannula being turned towards the fundus and sides of the bladder, the water is less disturbed by currents in the position referred to than in any other. Consequently, the last particles of débris gravitate towards this spot. Towards the end of the operation, therefore, the eye of the cannula should always be turned right round towards the prostate and water forcibly injected, so as to dislodge the débris from this position. This manœuvre is especially necessary where enlargement of the prostate coexists, otherwise a fragment might be left behind.

Litholapaxy was performed in three instances on female children, with the happiest results. The patient in each instance was running about the day after the operation, and suffering no inconvenience whatever. The operation is comparatively easy of performance in females, owing to the urethra being so short and wide. No forcible dilatation or disturbance of the parts was necessary, and consequently no incontinence of urine ensued; that troublesome sequel which so often results from the operation by dilatation.

Excluding the three cases in which the operation was performed in female children, there were 108 cases of litholapaxy in adult males performed by me, with four deaths, or a mortality of 3·7 per cent. Compare these results with the recognised mortality of one in four or five, or from 20 to 25 per cent., resulting from lithotomy in the adult. The accompanying table shows the results of 2592 lithotomy operations performed in the Indian hospitals during the year 1882. The figures are taken from the Medical Administration Reports of the various Provinces for that year, which, with the exception of that for the North-West Provinces and Oudh, are the latest available.

TABLE SHOWING THE RESULTS OF LITHOTOMY OPERATIONS PERFORMED IN INDIAN HOSPITALS IN 1882.

Presidency or Province.	Remaining on Dec. 31st, 1881.	Performed during 1882.	Total.	Result.				Remaining.	Percentage fatal.	Proportion fatal.
				Cured.	Relieved.	Otherwise.	Died.			
Bengal	6	181	187	148	5	5	19	10	10·5	1 in 9·5
North-West Provinces and Oudh ...	49	933	982	824	11	11	85	51	9·1	1 in 11·0
Punjab	50	949	999	768	25	28	127	51	13·4	1 in 7·4
Central Provinces	5	73	78	68	—	1	9	—	12·3	1 in 8·0
Bombay and Sinde	27	450	477	377	6	6	45	43	10·0	1 in 10·0
Madras	1	6	7	5	1	—	1	—	14·4	1 in 7·0
Totals	138	2592	2730	2190	48	51	286	155	11·0	1 in 9·0

I regret that I am unable to give the statistics of mortality according to age. The only administration report which is complete in this respect is that for the North-West Provinces and Oudh. Taking the latest statistics available for these provinces, those for 1883, I find that amongst 987 cases of lithotomy performed in 1883, the mortality up to the age of twenty years was 5·1 per cent., or nearly 1 in 20; between the ages of twenty and forty, 10·7 per cent., or about 1 in 9·5; and above forty, 31·9 per cent., or nearly 1 in 3. The mortality here recorded for the North-West Provinces is higher than that recorded for former years.

An impression seems to prevail in England as well as in India that lithotomy is a much more successful operation amongst natives of India than amongst Europeans. This impression is erroneous. According to the above table the mortality that occurred actually in hospital was 1 in 9, or 11 per cent. There were, however, 51 cases discharged otherwise than "cured," "relieved," or "died;" and it may be presumed that these, or the great majority of them, were taken away from hospital by their friends in a moribund condition to die at home. If these cases be added to those dying actually in hospital, the total mortality will be about 13 per cent., or nearly 1 in 8, which is practically the same as that recorded in Erichsen's Surgery as occurring amongst Europeans. In my own practice I have performed lithotomy in 182 cases; of these 50 were adult males, and amongst them there were 9 deaths, giving a mortality of 18 per cent., or about 1 in 5½. In the remaining 132 cases the patients were male children or boys under the age of puberty, and amongst them there was no death.

Lithotomy in the male child, when skilfully performed, has always been recognised as a successful operation. It

appears to me that litholapaxy is quite unsuited to such cases owing to the undeveloped condition of the genito-urinary organs, the bladder being small, the urethra narrow, and the mucous membrane of both extremely sensitive and liable to laceration. It must be remembered that, in order that the aspirator may be of any practical utility for removing fragments, a much larger cannula must be used than could with safety be introduced through the urethra of a male child. I am, however, unable to speak from practical experience in the matter, never having attempted litholapaxy in a male below the age of puberty; nor have I any inclination to do so whilst my success from lithotomy in such cases continues to be what it has hitherto been.

With litholapaxy in the adult male and females of all ages, and lithotomy in males below the age of puberty, the mortality from operations for stone should be extremely small. Second only to the reduction in mortality that litholapaxy can claim is the comparatively short period in hospital which the operation involves. It is no exaggeration to state that a disease which formerly involved weeks of confinement and suffering for its cure can now be disposed of in as many days.

I have referred to the impression which prevails that the mortality from lithotomy in natives is less than in the case of Europeans. There is also an impression prevalent to the effect that natives of India have no fear of the surgical knife. In fact, from the way some people talk and write it might be almost inferred that a native submits to a surgical operation as a kind of harmless diversion. This impression is altogether erroneous. A native of India will not, as a rule, submit to a surgical operation till all other modes of treatment fail, and he is driven to it through extreme pain, inconvenience, or danger to life. And it is for this reason that such large calculi are met with in this country, and that patients suffering from cancer and other diseases present themselves in hospital at a stage when surgical interference is useless. I can testify to the immense popularity of litholapaxy amongst the natives of India; and it may be reasonably hoped that when it becomes generally known that a small calculus may be removed from the bladder by an operation which involves no cutting, little or no pain, and confinement to hospital for a few days only, patients will present themselves at an early stage of the disease, when it is most amenable to treatment, and when the operation is almost unattended with danger.

In concluding this paper, I would venture to suggest that the time has now come when Bigelow's operation should be universally recognised as, what it undoubtedly is, a distinctly new operation. Shortly after the introduction of litholapaxy, Sir Henry Thompson assumed a position of opposition to this view. Sir Henry seems to have altered his opinions very materially since that time, for we find from his most recent writings that lithotrites and evacuating catheters which were then pronounced dangerous and unnecessary are now held to be admissible, and even necessary, when dealing with large calculi.

Now, everyone who knows anything about the history of lithotrity must be aware that previous to the appearance of Bigelow on the scene, in 1878, the tendency of all lithotritists was (1) to restrict to the lowest possible limit the time occupied at each sitting, four or five minutes being the utmost time allowed as safe; (2) to employ instruments of the smallest size possible; and (3) to leave the evacuation of the fragments as much as possible to natural efforts. The principles on which this practice was founded were: (1) That the bladder was extremely intolerant of the presence of instruments; and (2) that in direct proportion with the length of time instruments were manipulated there was the prospect of evil consequences resulting. There can be no doubt as to the teaching that prevailed on the subject. A reference to the latest editions of all the ordinary text-books published prior to 1879 will show that the authors were unanimous on these points; and there was no one who inculcated the principles and practice referred to more strongly than Sir Henry Thompson himself, as might be illustrated by numerous extracts from his writings. It was reserved for Professor Bigelow to show that these principles were altogether wrong, and to introduce a practice entirely at variance with the old proceeding. The hypotheses on which the new operation was based were: (1) That the bladder was much more tolerant of prolonged manipulation than was previously supposed, and (2) that the temporary manipulation of blunt and polished instruments in the bladder was less irritating than the continued presence in the organ of sharp fragments of calculus. For the purpose of working out his idea Bigelow introduced larger lithotrites than had previously been used, and invented an entirely new evacuating apparatus by which débris might be rapidly extracted from the bladder. In the introduction of the large evacuating cannulæ, Bigelow availed himself of the discovery of Otis that the urethra is much more capacious than was previously recognised. It is rather strange that Sir Henry Thompson should claim for Clover's syringe an efficiency as an aspirator which in its original and unmodified form it never possessed. The apparatus is referred to by most authors as a pretty and ingenious one for washing out the bladder. Its use in lithotrity is, however, deprecated, save in exceptional cases, such as where enlargement of the prostate or atony of the bladder coexists; and then the only efficiency claimed for it is that of washing out sand. Thus Mr. Cadge of Norwich writes:[1] "In doing this [removing calculi under the circumstances above referred to] I have sometimes used Clover's syringe, but more frequently have trusted to the quicker and less disturbing action of the scoop lithotrite." In 1869 Sir Henry Thompson, writing of the removal of fragments by Clover's syringe,[2] says: "The process is rather trying, however, for the bladder; and it costs rather more pain and time than an ordinary sitting for lithotrity." Again, in 1871, he writes:[3] "Having used it [Clover's apparatus] very frequently, I would add that it is necessary to use all such apparatus with extreme gentleness, and I prefer to do without it, if possible." And that, even so late as 1878, Sir Henry relied much more on the flat-bladed lithotrite for the evacuation of the débris (Fergusson's method) than on Clover's syringe is apparent from a passage in a lecture delivered by him in December, 1878, and published in THE LANCET, vol. i., p. 145, 1879.

Bigelow applied the name "litholapaxy" to his operation; but to this Sir Henry Thompson objects, suggesting "lithotrity at one sitting" as more appropriate. Now, I think there are many advantages in having a distinctly new name for a distinctly new departure in surgery. The word litholapaxy seems to me the one most expressive of the procedure involved in the new operation. Bigelow's operation involves much more than the crushing of the stone, the essential feature being its complete and rapid evacuation. Besides, as I have already pointed out, there are many cases in which a small calculus can be removed by the aspirator alone, in which no crushing is required, and to which, consequently, the name lithotrity at one sitting cannot be applied, whereas the word litholapaxy will also embrace these. There can be no doubt whatever that Bigelow's operation was a distinct innovation both as regards the principles involved and the means by which it was accomplished. The operation struck at the root of all previously held tenets regarding lithotrity; and its introduction caused at the time considerable astonishment to the profession all over the world. I must confess my surprise that Sir Henry Thompson, after employing Bigelow's operation in all its essential details during the past five years, and obtaining from it such brilliant results as those recorded by him, should still persist in saying[4] that "no new form of instrument is required by this operation."

Received at first with caution, the operation is steadily growing in favour with the profession in America, England, and Europe generally. In India it has as yet been adopted by a few surgeons only; but so thoroughly satisfied with its results in their hands is the Surgeon-General of the North-West Provinces and Oudh, Dr. W. Walker (always alive to the interests of surgery, and than whom no one has ever done more for its encouragement in India), that he has ordered several cases of the instruments required for employment in the most important hospitals under his administration. I believe I have pushed the operation, as regards the size and hardness of the calculi attacked, the ages and debilitated conditions of the patients operated on, as far as any other surgeon, and I cannot speak too highly of it. By it the surgery of the bladder has been truly revolutionised, and I confidently believe that, with increased perfection in the instruments and apparatus employed, larger calculi than any hitherto attacked will successfully yield to the operation.

Bareilly, India.

ELECTRIC ILLUMINATION OF THE VARIOUS CAVITIES OF THE HUMAN BODY, FARADISATION, GALVANO-CAUTERISATION, AND ELECTROLYSIS, BY MEANS OF POCKET ACCUMULATORS.[1]

BY FELIX SEMON, M.D., M.R.C.P. LOND.,
ASSISTANT-PHYSICIAN IN CHARGE OF THE THROAT DEPARTMENT OF ST. THOMAS'S HOSPITAL.

THERE are probably few members of the medical profession, whether engaged in general practice, pure medicine, surgery, or in pursuit of any of those specialties which necessitate a frequent examination of the cavities of the human body, who have not at some time or other been disagreeably struck with the insufficiency of the illumination offered to them in the residences of private patients or in the wards of hospitals. Even if the patient be able to walk about, the difficulties thus created are great enough; but they are increased tenfold if the patient be in bed and unable to move. Many kinds of apparatus have been devised to overcome these difficulties, but most of them are clumsy, expensive, and little calculated to meet the exigencies for which they were constructed, and none have come into general use. It is hoped that the apparatus herewith submitted to the profession will supply what is a real want.

Its history is briefly the following:—At a conversazione held at St. Thomas's Hospital a year ago, a little incandescent lamp attached to a rubber stem, and worked by a small bichromate battery, was shown by one of the students, Mr. Manners. The instrument was intended to illuminate the throat, its construction however was rather clumsy, and its illuminating power minimal. Some little time afterwards Mr. Arthur H. Vesey, a young civil engineer, and a friend of Mr. Manners, who was present, called on me and submitted a modified form of instrument constructed in accordance with some suggestions I had offered. Though considerably better, yet this instrument did not meet the requirements of the case, and ever since then we have been engaged in bringing it nearer to perfection. Our endeavours were mainly directed at first in constructing a useful laryngoscope; we thought we were near the desired goal when I left for the International Medical Congress held at Copenhagen in August of last year. On my way thither I spoke in Hamburg to a medical friend about the subject and described our instrument, when he told me the purpose for which we had so long been laboriously striving had already been accomplished by a Hamburg manufacturer of incandescent lamps, Mr. C. H. F. Müller. On visiting this gentleman I found the statement fully corroborated, and I now saw clearly before me the probability of being able to carry with me the light I required for a satisfactory examination, in a convenient form into the patients' homes, and at the same time of enabling me to perform those applications and operations which hitherto from the bulk of the apparatus and nature of the materials used in generating the electric current had practically restricted its employment to the practitioner's own residence.

All this is now overcome by the use of little accumulators and of the instrument to be hereafter described. Mr. Müller's laryngoscope was more perfect than ours, but still it was of little practical use, the mode of fixing the incandescent lamps at right angles to the stem of the mirror interfering with the patient's tongue, and rendering convenient use almost impossible. I explained these objections to Mr. Müller, who very readily fell in with my suggestions, and ever since has tried to comply with my wishes for further improvement in the accumulators and incandescent lamps. Since my return I have made further trials with Mr. Vesey, and Mr. F. Weiss has given us his invaluable aid. The instrument is the outcome of our joint labours after many patient trials. It may, perhaps, be thought that the following description enters too much into minute details; and I am myself quite conscious that a manipulation may appear very complicated if described too minutely; but, after mature consideration, I think it best to give as full a description as possible of its construction and mode of using, in order to furnish the practitioner with the information to which he may hereafter refer as a guide in any case of emergency. At the same time I desire to spare him those troubles and disappointments which I know from personal experience in the matter an autodidact would otherwise have to encounter.

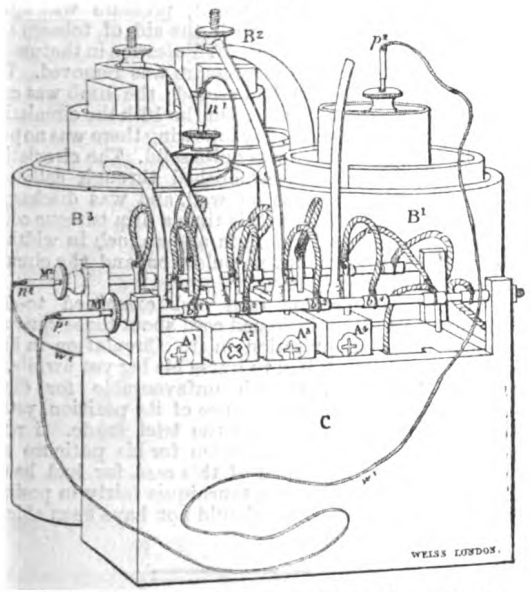
The fundament of the whole apparatus is formed by a little accumulator, which is four inches high, three inches broad, and three-quarters of an inch thick; its total weight, when filled with the exciting fluid, is only eleven ounces. The two openings through which it is filled must be closed, when it is carried about, by means of a small piece of indiarubber tube slipped over the projecting nozzles. If the accumulator be filled and charged with electricity, but not in actual use, it is desirable that one of the nozzles be left open, in order that any gas which may be generated may be allowed to escape, otherwise it would make an exit for itself through the casing of the cell, and injure it. Should the case be by any chance damaged in the foregoing or other manner, it may at once be repaired by the practitioner himself by means of an ordinary mouth blowpipe, which forms part of the apparatus, and a spirit-lamp. The method of doing so is as follows. A small piece of pitch is placed on the spot wherever the fault is found; it is then melted by allowing a jet of flame from the spirit lamp to impinge on it, and when melted is pressed firmly into place by the moistened finger or other suitable means. Care must be taken that the wick is divided in the flame in order that the jet of air may impinge on the flame, and not on the wick as well. The filling of the accumulators is accomplished in the following manner. A quantity of 10 per cent. solution of sulphuric acid is, by means of a little suction-ball, drawn into a pear-shaped glass bulb, tapering off into a pipette. The latter is inserted into one of the nozzles before mentioned, and emptied by slow steady pressure upon the suction-ball. The pressure must be slow, to allow all the air within the accumulator to escape. The pipette, when emptied, is withdrawn, filled with solution, and the injection is repeated. This process must be proceeded with till both nozzles overflow. It will be found that only very little fluid can be got into the second nozzle, and I have little doubt that there must be some communication between the two cells of the accumulator. Mr. Vesey, in fact, states that such is the case in many of them. In one or two of my accumulators I have even found that the whole cavity can be filled by one nozzle, and when quite full the liquid overflows from the other. The average amount of liquid required varies from one ounce to one ounce and a half. In order to charge the accumulator with electricity, all that has to be done is simply to connect its positive pole with the positive pole of the battery, and its negative pole with the negative pole of the battery. The battery used for the purpose is a Bunsen, consisting of two cells. *It is most essential that no mistake be made regarding the poles in connecting the accumulator with the battery*, for I am assured by Mr. Müller that the accumulator would at once be spoiled if such a mistake were to occur. Again, it is very important that the connexions should be kept clean. They ought now and again to be rubbed with a small piece of emery paper in order to ensure a good contact. The Bunsen cells may be charged in the usual manner—that is to say, with a 10 per cent. solution of sulphuric acid in the outer jar and nitric acid in the inner. As, however, this arrangement gives off obnoxious fumes, the nitric acid may be advantageously replaced by the so-called Ecker's fluid. This is prepared by dissolving one part of bichromate of potash in four parts of hot water, and adding two parts of nitric acid when the solution has cooled down. It gives off no fumes either when in use or at rest, and the power of the battery is hardly impaired. The Bunsen cells should be quart ones. It has been calculated that to charge one accumulator and two Bunsen cells with the requisite quantity of fluid costs about 2*s.*, but as the solution of sulphuric acid may be used from three to four times and the Ecker's fluid from six to eight times, the real cost of once charging will amount to only about 6*d.* When it is further borne in mind that from one to four accumulators may be charged at the same time from three cells, the cost is still further reduced.

According to Mr. Müller's directions the accumulators ought to be left only from one hour to one hour and a half in contact with the battery. Mr. Weiss and myself have, however, found that though this time suffices to charge them quite satisfactorily, yet after they have been properly

[1] A paper read at the Medical Society of London on Feb. 23rd.

"matured" they may be safely left in connexion from two to three hours, or even more. No doubt the difference between introducing fresh Ecker's fluid and sulphuric acid solution, and the length of time the battery has been at work without being refreshed, has a great deal to do with the length of time that the accumulators take to charge, so that the longer the battery has been in use without having fresh fluid the longer may the accumulator be left in contact with it. I am, however, not in a position to give reliable information with regard to the maximum of time during which the accumulator may be with impunity left in connexion, having had only a few to experiment with, for very different purposes. A simple way of ascertaining whether electricity flows from the battery into the accumulators, or whether, the accumulators having been fully charged and the battery being exhausted, it goes in the opposite direction, consists in disconnecting the battery and the accumulators after they have been in connexion for more than one hour and a half, and in testing the electro-motor force of each by means of the galvanometer. As soon as the

FIG. 1.



Showing method of charging several accumulators simultaneously. (The case is made for six accumulators, but only four are represented in the engraving.) A^1, A^2, A^3, A^4, Accumulators, the positive (+) poles of which are turned towards the spectator. B^1, B^2, B^3, Three Bunsen cells, connected together for intensifying. C, Charging case. w^1, wire connecting the positive pole of the battery (p^1) with the positive poles (p^2) of the accumulators. w^2, Wire connecting the negative pole of the battery (n^1) with the negative poles (n^2) of the accumulators. b^1, b^2, b^3, b^4, Branch wires connecting wires leading from the main connecting (M^1 and M^2) to the terminals of the accumulators.

indicator is as much, or even more, deflected by the accumulators than by the battery itself, it is conclusively shown that the charge of the accumulators is as complete as it can be. The whole time of filling four accumulators with sulphuric acid solution, charging three Bunsen cells with fluids, and connecting occupies less than ten minutes. It will prevent disappointment to know that a new accumulator neither takes nor retains the charge so well as a matured one, and that, in fact, it works better the more it is used. After completion of charging the accumulators should be disconnected from the battery, and the battery itself taken to pieces, the zinc plates rinsed in water and the porous pots be allowed to soak in a pail of fresh water in order that all sulphate of zinc which may have got into the pores may be dissolved out. A fully charged accumulator will retain sufficient power to illuminate an incandescent lamp for a period varying from ten to fourteen days. If the accumulators are in frequent use, it is desirable that a little of a 10 per cent. solution of sulphuric acid be introduced occasionally in order to make up any loss by evaporation or otherwise. After they have been in use some time, it is desirable to empty all the fluid out, and rinse them with clean water. The removal of the fluid is effected by simply shaking the accumulator over a basin. Several accumulators may be charged simultaneously. The number of elements required depends upon the number of accumulators to be charged. It has been found that three Bunsen cells are sufficient to charge four accumulators; four cells, six accumulators, and so on. I need hardly say that the primary battery by no means offers the only way of charging the accumulators. Those who have water power at command may easily set up a small dynamo-machine driven by a turbine. I may mention that should there be a sufficient demand for the apparatus, Mr. Weiss will set up a dynamo-machine in his workshop, where the accumulators may be sent when empty, and returned fully charged after a few hours. The accumulators are available for electric illumination of different cavities of the body, for faradisation, galvano-cauterisation, and electrolysis.

(To be concluded.)

RESULTS OF AMPUTATIONS AT THE NEWCASTLE-UPON-TYNE INFIRMARY DURING 1883-84.

BY FREDERICK PAGE,
SURGEON TO THE INFIRMARY, AND EXAMINER IN CLINICAL SURGERY AT THE EDINBURGH UNIVERSITY.

TABLE I. details the nature and the results of the major amputations performed antiseptically in the Newcastle-upon-Tyne Infirmary during the year 1884. Fifty-seven major amputations with three deaths (5·2 per cent.) is a good result. Two deaths followed amputations for injury. In one case a man was admitted with a severe compound fracture of the metacarpus; tetanus supervened, from which the patient died, after the forearm had been removed. The other case

proved fatal a few hours after primary amputation of the thigh from shock and loss of blood. Twenty-one amputations for injury, with two deaths (9·4 per cent.), is not, perhaps, a sufficiently satisfactory result. The remaining thirty-six amputations were for disease, and only one patient died—a man aged fifty-three years, whose tissues were in an advanced stage of fatty degeneration—forty-eight days after amputation through the middle of the thigh for spontaneous gangrene of the foot and leg. The cause of death was gangrene recurring in the stump. Thirty-six amputations for disease with one death—2·7 per cent—is very satisfactory.

Table II. gives the results of amputations in the infirmary during the years 1883-84. One hundred and five major

amputations in a large provincial hospital, spread over a period of two years, with six deaths—5·7 per cent.—none of which were due to hospital causes, is a result which a few years ago, certainly at the time Sir James Y. Simpson wrote his article on "Hospitalism," few, if any, hospitals could show, and speaks eloquently for the improved method of treating wounds, which Sir J. Lister has done so much to perfect.

Newcastle-on-Tyne.

ON A CASE OF

ILIO-FEMORAL ANEURYSM, TREATED BY INSTRUMENTAL COMPRESSION; CURE.

BY W. BERRY, M.R.C.S., L.R.C.P. & S. ED.,
HONORARY SURGEON TO THE ROYAL ALBERT EDWARD INFIRMARY, WIGAN.

THE notes of the following case of ilio-femoral aneurysm are interesting, especially as they prove the dictum of Mr. Bryant in his work on Surgery, page 463, second edition, where, in writing of ligature of the external iliac artery, he says: "This operation may be required for aneurysm of the common femoral for wound or for any other cause in which it is necessary to arrest the flow of blood through the lower extremity. It should not, however, be performed for any disease unless pressure of the artery, digital or instrumental, has proved ineffectual or is inapplicable; for Mapother,[1] Eck,[2] and Hilton[3] have all recorded instances of cure of inguinal aneurysm by these means." This case was sent to me by my friend, Dr. Hannah of Ashton-in-Makerfield, and my first intention was to ligature the external iliac, this operation to my mind affording the only chance of cure. At a consultation with my colleagues of the infirmary staff it was thought advisable to try pressure in the first instance, and if failure followed, then to ligature the vessel above the aneurysm. The application of compression was not easy to accomplish, and much credit is due to the indefatigable perseverance and ingenuity of our senior house-surgeon, Dr. Jackson, and also to the courage exhibited by the patient himself, which led to a successful result as a reward for their efforts. I am indebted to Dr. Jackson for the following notes:—

George S——, aged forty years, a collier, was admitted into the Royal Albert Edward Infirmary on Aug. 21st, 1884. He then stated that whilst following his employment seven weeks previously he had been injured in the right thigh by a runaway coal-tub. Immediately after the injury he felt a shooting pain in the region of the right groin, which lasted about fifteen minutes. There was no external wound or abrasion of the skin, but poultices were applied on account of the pain. Patient continued to work, and about two days afterwards noticed a small lump in the right groin, which had continued to enlarge. He continued to work until a week after the accident, when he was idle for three weeks, in consequence of a lock-out at the colliery; after this he worked one week, and then "strained" himself again, and was laid up. The patient has been married sixteen years, and has three healthy children; he lost one, aged fourteen months, from consumption of the bowels. There is no history of syphilis, but there is a circular scar about the middle of the dorsum of the penis, which he states was caused by a wound he received in the mine. He had gonorrhœa twenty years ago. On examination, a pulsating tumour, the size of a large walnut, was found immediately below the right Poupart's ligament, at a point corresponding with the position of the femoral artery. The patient was placed on milk diet, and ten grains of iodide of potassium, three times a day, were ordered. On Sept. 2nd he went home, against the wish of the house-surgeon, without any improvement having taken place. On Oct. 1st he was readmitted. The tumour could now be felt pulsating above Poupart's ligament and as far down as a point two inches below it, and was one inch in width. The patient was again put on milk diet and fifteen-grain doses of iodide of potassium three times a day, and after a consultation with the staff it was decided to apply pressure to the external iliac artery. On the 9th the patient was placed in a small ward alone, and at 2 P.M. had three-quarters of a grain of morphia hypodermically and the right leg enveloped in a fold of cotton wadding. Pressure was then applied to the external iliac by means of a Lister's tourniquet until the pulsation in the tumour ceased. In about half an hour the patient became very restless and complained of pain, and all circulation in the limb appeared to have ceased. He was then allowed to smoke, and, having been deprived of this (a favourite enjoyment of his) for over a week, submitted cheerfully to the pain for another hour. At 3.30 P.M. the pain was so severe that chloroform had to be administered, and this was continued until 6.15 P.M., making in all four hours and a quarter of continuous pressure, when the tourniquet was removed. On the 10th the pulsation in the tumour was slightly (?) diminished, the patient feeling comfortable. On the following day the patient was in much the same condition. The bowels were relieved by a dose of castor oil. On the 12th the pulsation in the tumour was apparently as strong as ever; the leg was flexed on the thigh and the thigh on the abdomen with a roller bandage in the groin, for one hour and a half both morning and evening. Next day the leg was again flexed, as before, for two hours and a half. No result followed this procedure. On the 14th the pulsation was as strong as at the commencement of treatment, pressure was again applied by Lister's tourniquet, with the aid of tobacco and chloroform, for three hours and a half. Pulsation in the tumour had entirely ceased when the pressure was removed. The following day the pulsation had ceased; the limb was cold but the patient was comfortable. On the 16th the circulation in the limb returned. On the day following there was no pulsation in the tumour, which was quite solid. The circulation in the limb was quite re-established through collateral channels. The patient went on well, and was discharged cured on Nov. 3rd, 1884. At this time a firm tumour could be felt an inch and a half in length and an inch in width at the seat of the aneurysm, but no pulsation, and the circulation in the limb perfectly good.

Jan. 27th, 1885.—Patient seen and examined to-day. Tumour now feels like a thickened cord about three-quarters of an inch thick; no pulsation in it. Circulation in limb keeps good, but he is advised to nurse his leg yet awhile.

Remarks.—This case, though unfavourable for direct pressure owing to the circumstance of its position, yet by the result amply repays one for the trial made. I must here tender my thanks to Dr. Jackson for his patience and perseverance in the treatment of this case, for had he not sat by the patient and kept the tourniquet fairly in position over the artery, I am sure we should not have been able to record this successful issue.

ON

SYNCOPE, AND A METHOD OF AVERTING IT.

BY WILLIAM J. NOTLEY, M.D., B.A. LOND.

IN whatever way syncope may be produced, whether by an impression made primarily on the higher cerebral centres, or by influences carried along the peripheral nerves to these centres, and thence in both cases reflected to the heart and other organs of the body, there can be no doubt that the unconsciousness, either partial or complete, which forms the principal symptom of the condition is due to a deficient supply of blood to the brain. Cases of syncope may be divided into two classes: first, those which are due to some mechanical obstruction to the circulation arising in the heart itself, or in the great vessels springing from it, and secondly, those which are the result of various impressions made either on the peripheral nerves or on the emotional centres in the cerebrum. To the former class belong those cases of valvular and aortic disease which terminate in fatal syncope, as well as those in which, from the weakness of the circulation at the end of exhausting maladies, ante-mortem clots are formed, which, by interfering with the exit of the blood, terminate the life of the patient.

In the other class of cases the cause is often external to the organism. A blow on the abdomen, by its effect on the mesenteric nerves, gives rise to an impression which, travelling along the spinal cord, reaches the medulla, and is thence transmitted along the vagi to the heart, resulting in a retardation or a complete stoppage of that organ. The same effect, it is well known, may arise from an impression made on the terminations of any of the afferent nerves

provided it be sufficiently strong to produce, not merely a sensation, but also a reflection. In other cases belonging to the same class the impression is made primarily on the higher centres of the brain, and is in the nature of an emotion of joy or fear, or some other strong passion. From these centres, if the impression is strong enough, or if the nervous system is in that state of mobility allied to weakness, in which the liberating forces are in excess of the inhibiting ones, the impression is conducted to the medulla, and from it to the heart, along the same channels as those before named.

Now, in all cases where the syncope is not complete, and where the heart continues to act, though feebly, measures are usually taken to restore the patient by adopting such means as are calculated to strengthen the action of the heart and facilitate the flow of blood to the brain. In many cases a person accustomed to faint from slight causes will be able to avert the syncope by adopting such means, and it is for this purpose that I wish to draw attention to the efficacy of heat applied to the head. In a person with a weak heart syncope may be produced by simply sitting with the feet in hot water, and, in like manner, it may be averted by the application of heat to the head. Anyone may convince himself of this by first producing faintness in himself artificially. This may easily be done by getting into a bath of about 110° F. In a few minutes he will begin to feel faint. Let him then plunge the whole of his head except the nose and mouth beneath the surface of the water, and in less time than it has taken to bring on the faintness all the disagreeable sensations will cease, and he will now be able to continue in the bath, perhaps for half an hour longer, without any inconvenience. From this it would appear that the application of heat to the head is a measure of some value in averting a threatened attack of syncope.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas at morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

ST. MARY'S HOSPITAL.

FORMER DESTRUCTIVE ARTHRITIS OF THE KNEE-JOINT; DISLOCATION WITH BONY AND FIBROUS ANKYLOSIS; RESECTION; UNION BY FIRST INTENTION AND WITHOUT SUPPURATION.

(Under the care of Mr. A. T. NORTON.)

OSSEOUS ankylosis of the knee-joint with backward displacement and rotation of the leg, rendering the patient quite unable to walk, as in the case described below, is usually the result of inflammatory changes following injury. It is now comparatively rare to meet with extreme degrees of such deformity, careful attention on the part of the medical attendant and improved methods of treatment preventing such result. The operation which Mr. Norton performed in this case, removal of a wedge-shaped piece, including parts of the femur and tibia with the patella, is the best when the deformity is the result of disease, as in his case; it permits of removal of any lurking mischief, as well as correction of the deformity. The other operations which have been practised for the cure of this condition are, briefly, fracture of the femur after subcutaneous drilling of the bone, excising a wedge-shaped portion of the femur above the joint, osteotomy of the femur and of the tibia, and subcutaneous division of the line of union by means of a chisel or other instrument introduced from the outer side, followed by gradual extension of the limb.

For the following notes we are indebted to Mr. French.

The patient, E. W——, a fairly healthy looking girl, aged ten, was admitted into St. Mary's Hospital on Sept. 30th, 1884. The family history was good. The patient herself had always been healthy but had suffered from corneal ulcers, the scars of which could be seen in the left eye. The history was that four years ago, without any known cause, the left knee began to swell and became painful, especially when the patient attempted to walk. To ease the pain she kept the joint flexed and used a crutch to get about. There had been no suppuration.

On admission the left knee-joint was found to be uniformly enlarged with a good deal of pulpy synovial membrane and firmly or immovably ankylosed with the leg almost at a right angle with the thigh, and the lower bones dislocated backwards, outwards, and rotated outwards. The patella was also ankylosed to the femur. The knee was not tender and only painful when weight was put upon it. There was wasting of the muscles of the limb. The ankylosis was so firm, not only within the joint but without it, and the dislocation of the tibia from the femur so great, that it was clearly evident that the deformity could not be overcome. The limb in that condition was quite useless to the child. She was unable to bring the foot to the ground and could only walk by means of crutches. It was, therefore, decided to resect the joint.

On October 15th, after consultation, the patient was taken into the theatre and put under ether, and Mr. Norton proceeded to excise the joint. The circulation was arrested by the Esmarch cord. The usual horseshoe incision was made, and the flap dissected up from the patella. The capsule and ligamentum patellæ were then cut through, and the tibia forcibly flexed on the femur, but it was impossible to break down the ankylosis, which was bony, even with the raspatory and lever. Almost the whole of the lower epiphysis of the femur with the patella attached, and a slice of the upper end of the tibia, were then sawn off. The ends of the bone were adjusted, and the edges of the wound were brought together with wire sutures. A small drainage-tube was inserted at each side of the joint, not through the wound, which was entirely closed, but through small openings made for the purpose. The operation was performed under the spray and the wound dressed with Listerian dressings and salicylic wool. After the operation the limb was put up on a back splint made to fit the child with outside splint attached, and interrupted in the region of the wound in order to apply the antiseptic dressings. Ice-bags were suspended on the leg both above and below the dressings. After recovering from the anæsthetic, the patient was very restless, so one-eighth of a grain of morphia was administered subcutaneously, and minim doses of sedative solution of opium ordered to be given every hour if necessary; but during the night three doses of one minim each were given.

On the following day the knee was dressed; there was a small amount of serous discharge. Tubes syringed out with iodine lotion (half a drachm to the ounce). The patient complained of slight pain in the knee. Morning temperature 99·5°, evening 101·3°.

The knee was dressed again on the following day, after which it was left for three days as no discharge came through the dressings, the highest temperature being on the third evening, 101·3°.

On the 26th the stitches were taken out, the whole wound having united by first intention, except where the tubes were. The tubes were shortened at each time of dressing, and finally left out on Nov. 6th, when the bones were found to be firmly united, three weeks after the operation.

The interrupted splint was left off on the 13th, and an iron back splint was applied; the Listerian dressings were also discontinued and the knee dressed with salicylic wool.

On the 18th a small superficial abscess formed in the upper flap, which was opened, and half a drachm of pus escaped; the cavity was circumscribed and did not extend to the bone.

On the 27th the note is as follows:—"The patient can stand without pain and walk without assistance and without crutches. On measurement there is found to be two inches and a half shortening of the affected limb, but this is not very visible when the patient stands up, even with ordinary boots on."

She was discharged with the wound perfectly healed on Nov. 27th, six weeks after the operation.

LIVERPOOL ROYAL INFIRMARY.

CASE OF COMPOUND DISLOCATION OF THE ELBOW-JOINT, WITH DIVISION OF THE MAIN ARTERY AND VEIN, HEALED WITH RESTORATION OF ALL MOVEMENTS; REMARKS.

(Under the care of Mr. RUSHTON PARKER.)

A WOMAN, aged twenty-eight, fell downstairs on April 13th, 1883, and was admitted into the Liverpool Royal Infirmary shortly afterwards. The house-surgeon on duty, Mr.
